With the coming of hot weather, the scenes of distress are repeated with the same poor hard-worked brute as the chief actor once again. So looking at it from all points of view, it would appear as if the commercial vehicle has the advantage in cold weather, in hot weather, and, of course, in moderate weather; in short, the advantage is at all times in the gasoline-driven machine.

RACING CONTROL IS NOW UNDER A REVISED PLAN

HARMONY in the automobile racing situation seems to be a well-nigh accomplished fact in this country, a condition which has been a stranger to American contest circles for many long months, and all this was secured as a result of a number of meetings held in Chicago during the show.

While the Contest Board of the A. A. A. will have matters in charge, with power to grant sanctions, in all of its actions it will be, more or less, advised by a committee representing the Association of Licensed Automobile Manufacturers, the American Motor Car Manufacturers' Association, and the Importers' Automobile Salon.

The movement which has culminated in this amicable agreement is not a new one and has been slowly attaining importance for some time. In January, during the Madison Square Garden Show, a number of manufacturers met and decided to form a Manufacturers' Contest Association at Chicago; and this was done, membership being limited to makers who have built fifty or more cars, and importers who have brought a like number to this country, although non-members will still be eligible to compete in events. The organization was completed by electing Benjamin Briscoe, of the Maxwell-Briscoe Motor Company, as president; W. E. Metzger, of the E. M. F. Company, as secretary-treasurer; Russell A. Field, of New York, as his assistant, and Howard E. Coffin, of the Chalmers-Detroit Company, as chairman of the committee on rules.

Of the twenty-five members constituting this body, the following five were selected, with Mr. Coffin, to act as an executive committee: Elmer Apperson, Apperson; George Weidley, Premier; Paul LaCroix, Renault; A. L. Riker, Locomobile, and one other yet to be announced. It was then that a committee was appointed which should confer with the A. A. A., and this was composed of Howard E. Coffin, Alfred Reeves, of the A. M. C. M. A.; E. P. Chalfant, of the A. L. A. M., and E. R. Hollander, representing the importers.

At the same time the Executive Committee of the A. A. A. was preparing to meet the manufacturers half way by authorizing the appointment of a committee to confer with them and composed of F. B. Hower, L. R. Speare, Powell Evans, and F. H. Elliott. This body, together with those from the M. C. A., composed the court which took up the matter of a joint and harmonious action in controlling automobile contests in America, on road and track, and the questions discussed were those which have been bothering autoists all over this country and have even affected the makers in Europe. Supporters of the A. A. A. have at times seen reason to criticize, but at the same time have realized that the only solution of the problem could be through a national body vested with complete but advised authority.

The result has been satisfactory so far, and with men who are thoroughly familiar with the conditions, discussing and arranging them, it is felt by those most vitally interested that a staple condition will be obtained. The manufacturers have made it plain that they do not wish to become identified with the promotion of the contests, but at the same time that they should be consulted, that they desire to have the number of races limited, and both the races and endurance runs supervised in regard to rules and other regulations. The A. A. A. committee has reported favorably upon the arrangement whereby it should have control of these affairs with an advisory board from the M. C. A., and it is assured that on March 2 this will be ratified at the meeting of the executive committee of the A. A. A. in New York

Of premier importance to makers was the proviso adopted that all rules for contests of a certain year must be published by September 1 of the preceding year, thus those for 1910 events will be given out next Fall, and at the same time this makes the rules adopted for this season's contests and already considered remain in force. One point which was brought up was the attitude of the A. A. A. toward racing on one-mile tracks, a practice which it has recently refused to sanction, and this difficulty has been overcome by the recommendation that the national body again sanction these meets, but with the understanding that some representative of the Contest Board must be in attendance.

Still another phase to be considered was that of the term "international," which will be so defined that a promoter cannot dodge the issue of obtaining a sanction by simply enlisting a few foreign cars and then calling the meet an international one. It is the general opinion that whatever differences of opinion have arisen in the past among the various motoring organizations as to the status of this term will not be reopened.

This condition of racing affairs is one that will undoubtedly be of great benefit to the industry, to the sport, and to the realization that there must be a national governing body, and that if the latter has been open to criticism in the past, that fact does not give a reason for belittling the necessity for it.

The Contest Board of the A. A. A. is composed of Frank B. Hower, chairman; Frank G. Webb and A. L. McMurtry, and the Advisory Board, A. L. Reeves, E. P. Chalfant and E. R. Hollander. Some autoists feel that it would perhaps be better to have a separate board for speed races, leaving touring contests under the control of the present body, but at present the existing arrangement seems to be the program.

TRANS-CONTINENTAL CONTEST TO SEATTLE FAIR

A TRANS-CONTINENTAL endurance run from New York City to Seattle on account of the Alaska-Yukon-Pacific Exposition, which opens in that city on June 1, is the latest competition proposal in autoing. From the interest already taken in the event it may become a real cross-country race with a goodly number of foreign and American entries. The trophy presented by M. Robert Guggenheim, valued at $2,000, gives this title to the contest: "An International Contest for the M. Robert Guggenheim Trans-Continental Trophy and Cash Prizes, under the auspices of the Alaska-Yukon-Pacific Exposition and of the Seattle Automobile Association."

John Kane Mills and T. Francis Moore, of New York City, have been given charge of the affair, and for two months they have been working upon routes, rules and plans in general, and on Monday evening of this week the latter member of the firm started for Seattle with the tentative rules and regulations in his pocket. With the directors of the exposition these will be taken up in detail and a definiate understanding made as to the conduct of the contest.

Starting either on May 15, as desired by the Westerners, or on June 1, as suggested by the New Yorkers, it is generally thought that the winner will take about twenty days to make the run across the country over a route about 3,900 miles in length, with few rules, few checking places and in many cases far enough away from railroads so that the cars will be competing under touring conditions. As proposed, the route taken will lead the cars from New York City to Albany, Buffalo, Cleveland, Chicago, Clinton, Ia., Dennison, Neb., Omaha, North Platte, Cheyenne, Wyo., Granger, Pocatello, Montpelier, Boise, Burns, Salem, Portland and into Seattle. The only new part of the course will be that west of Granger, nearly all of the others having been covered in previous contests.

Already five foreign car entries are promised, with famous touring drivers slated to appear on American soil to try again to

make a better showing than in the last race across the United States. American cars are assured by both makers and dealers, and the dates proposed will be such as to cause no conflict with the annual tour for the Glidden Trophy, which usually starts the second week in July.

Of rules there are few, advisedly so because the contestants will not travel in numbers, and the ones gotten up must be sanctioned by the Seattle people before being given out. It is known, however, that it will be a case of first into Seattle to win the trophy and $2,000 in cash, with enough intermediate checking stations to prove that the cars have been driven over certain routes. A list of hotels will be compiled at which the night and day clerks will be the official checkers. No observers will be carried, and the cars can be rebuilt if necessary, except in the case of the frame, which is considered the car's foundation.

The rule which has caused widespread comment, however, is that although drivers may be changed or relayed, yet they cannot leave the car in which they started, and when tired and sleepy must fall back into the tonneau to get their rest. Of trophies and prizes there are enough to satisfy those who qualify, the winner getting $2,000 besides the trophy; the second car taking $1,500; the third, $1,000; the fourth, $750, and the fifth securing $350. In case an amateur does not wish to take cash, plate may be substituted.

There is time enough before the start for such a thorough discussion of the points that it is expected that all will be clear and well arranged and there is extended interest even at present hinging over the rules. It has been suggested that to eliminate somewhat the grind upon the participants that at least two stops of twenty-four hours each shall be included, one at Chicago and the other at Cheyenne.

Just how this race will affect the one planned by the New York *Times*, to start for San Francisco on the fourth of July, is not known, some thinking that perhaps the one contest will do for both and that a second one would not be attempted, others thinking that perhaps both might be combined on the earlier date.

FOUR PERFECT SCORES IN ROCHESTER MID-WINTER RUN

ROCHESTER, N. Y., Feb. 15.—Of the sixteen cars entered in the Rochester Automobile Club's first annual mid-winter endurance run, four finished without a single demerit charged against them. Of these, two were in Class A and two in Class B. A source of great local pride is the fact that three of the four to go perfect were born and brought up in Rochester, so to speak.

To put it mildly, the weather conditions were fierce. The drifts encountered were fully as bad as those which the New York-to-Paris racers ran into just a year ago, the snow being fully four feet deep in places. The wind, a 40-mile gale, blew right into their faces for half of the trip. Not a few of the drivers had fingers or toes frozen, while all of them were bundled up so that movement of any sort was unpleasant. In one case this was the cause of a demerit, as Driver Davis of No. 1 Gaeth ran into a snowbank and while trying to throw the clutch his feet became entangled in the robe and the engine stalled. This cost him one point.

All of the starters reached Buffalo except two, but the road beyond that city was the scene of the first and only serious accident. This happened to No. 9, Selden, driven by Hector Caramella, which was going at a fair clip towards Rochester when, upon rounding a curve, another car was overtaken. Not having time to bring his machine to a stop, Caramella drove up an embankment at the side of the road. This caused the car to turn turtle, throwing the occupants out.

No. 7, Selden, driven by Charles Young, set out at the start to go over the route as quickly as possible, and was promptly disqualified for speeding. Young arrived in Buffalo two hours ahead of the pacemaking car and promptly started back. He finished over five hours ahead of the bunch. The result of the contest was that two cars finished with perfect scores in both classes. These are No. 5, Selden, driven by W. C. Barry, Jr., and No. 10, Gearless, driven by F. C. Shannon, in Class A; No. 6, Selden, driven by Henry Selden, and No. 15, Cadillac, with Richard Guyer at the wheel carried off the honors in Class B.

The club officials have announced that some day next week the double tie will be run off to determine the possessors of the silver cups. This run-off will probably take place over a different route than the contest, but this route has not yet been announced.

These were the participating cars:

Number	Car	Entrant	Driver	Result
5 A	Selden	W. C. Barry, Jr.	W. C. Barry, Jr.	Perfect
10 A	Gearless	Gearless Co.	F. C. Shannan	Perfect
6 B	Selden	H. R. Selden	H. R. Selden	Perfect
15 B	Cadillac	Mabbett & Betts	R. Guyer	Perfect
1	Gaeth	Outhout & Henry	O. W. Davis	1 Point
3	Cadillac	Mabbett & Betts	H. Pye	1 Point
2	Cadillac	Mabbett & Betts	Betts	.....
4	Oakland	L. B. Kirkpatrick	Mercier	.....
11	Buick	C. L. Whiting	C. L. Whiting	.....
13	E-M-F	Peck &Brooks	Peck	.....
14		Peck &Brooks	Brooks	.....
7	Selden	Geo. B. Selden	C. Young	Out for speeding
9	Selden	Selden Co.	H. Caramella	Out—overturned
12	Buick	C. L. Whiting		Out

FLORIDA'S 1909 BEACH RACES.

New events and classifications have been prepared for the annual races on the Florida beach, which will be run this year at Daytona from March 23 to 26, under the patronage of the Florida East Coast Automobile Association and promoted by the Motor Contest Association, Inc., of which Senator W. J. Morgan is manager. Price and piston displacement have been used to divide the cars in the longest of the events. Twenty-two races altogether have been scheduled, of which only ten are for autos, the others being for motorcycles, bicycles and aeroplanes.

At 200 miles each are the Florida stock car and piston displacement races, with first, second and third moneys in each and an additional one for the driver doing best in both. The regular race for the Minneapolis trophy will be held, as will also that for the Two-mile-a-minute Speed Crown and the mile time trials for the Sir Thomas Dewar trophy. An international free-for-all at one, five and ten miles; a Southern price and horsepower handicap; a Vanderbilt Cup competitors' race, and an invitation match race for George Robertson, Louis Strang, Herbert Lytle, Ralph De Palma and other noted drivers complete the list.

NATIONAL'S THOUSAND A DAY.

INDIANAPOLIS, IND., Feb. 16.—The National Motor Vehicle Co. has come to the front with a brand new proposition in automobile circles. One thousand miles a day for ten days is the modest feat the company will attempt some time in May or June.

Arrangements have already been completed to have the event on the track of the Indianapolis Motor Speedway Co., which is now being built, and will be completed some time between May 15 and June 1. The 1,000 miles a day for ten days event will be among the first on the speedway.

WANTED: A BRIARCLIFF QUORUM.

NEW YORK, Feb. 16.—Lack of a quorum to-day prevented, for the second time, a meeting of the manufacturers' committee in charge of the Briarcliff race, and again it was postponed, this time until next Monday, when it is hoped that all the members will have returned from Chicago and attend. In the meantime, as the date desired for holding the contest approaches, the probability of securing acceptable rules diminishes.

CLUB GOSSIP FROM FAR AND NEAR

OLD BICYCLE CLUB BECOMES NEW AUTO BODY.

PHILADELPHIA, Feb. 15.—On Friday evening last, at its handsome home, 1606 North Broad street, there was effected a reorganization of the Century Club (formerly the Century Wheelmen), whereby, by the addition of a half-hundred new motoring members to the score or more already on the rolls, the famous old organization will seek future fame under the title of the Century Automobile Club.

Something less than a decade ago the Centuryites had a strong automobiling element in their membership—so strong, indeed, as to warrant the officials in transforming the club's huge wheelroom into an up-to-date club garage. Two or three years later, with the formation of the local automobile clubs, Century's motoring element drifted away, and the bowling craze having just about that time hit the city, the club management effected another transformation in the erstwhile wheelroom by installing four up-to-date alleys, and the Century Club (the "Wheelmen" having been discarded some years before) pursued a quiet existence as a social club.

Always wide awake, the Centurians some time ago saw an opportunity of injecting new life into their organization by offering inducements to local motorists to join them. The principal one of these was the club house itself, the only other autoing organization in the city having one being the Germantown Automobile Club.

In announcing its future policy, a prominent official of the club said that endurance runs, hill climbs and other contests would be promoted by the club at suitable intervals, but that it would be the primary object of the contest committee—which, by the way, is to include only men not connected with the trade—to formulate a set of rules which will give the private owner a chance with the entrant who is in the trade, and who, therefore, has an undue advantage over the "layman." This will be brought about by making separate classes for private owners and trade members. To insure absolute justice in the contest committee's decisions, a rule will be formulaated to debar from service on the committee, for the time being, any owner who may have entered a car in the run or hill climb or other event than *en tapis*. This radical rule will. it is hoped by the Centurians, effectually prevent the bickerings, protests and heartburnings which have invariably followed the contests promoted locally heretofore.

NON-OWNERS MAY JOIN A. C. A.

NEW YORK CITY, Feb. 15.—A new class of membership has been adopted by the Automobile Club of America for persons interested in automobiles but not owners of them. This will be known as "Clubroom membership," with the privileges of the assembly, grill, billiard and general social rooms and the library, but without those necessary to owners of cars, such as the garage facilities, touring information and maps.

The new class is limited to 100, and will allow those elected to it to enjoy the benefits of the luncheons, lectures and entertainments given by the club. There is no initiation fee attached, and the annual dues are $25.

CHATTANOOGA PLANS CARNIVAL.

CHATTANOOGA, TENN., Feb. 15.—Under the auspices of the Automobile Club of Chattanooga a carnival will be held on March 16, 17 and 18. A hill climb will take place on Lookout Mountain. and speed contests on a mile track at Olympia Park. Three cups for the latter have been offered, one by the Chattanooga Automobile Club, one by the chamber of commerce, and the third by the Patten Hotel. The trophy for the Lookout Mountain climb has not been decided upon. The danger of the latter course has been lessened lately by the placing of heavy fences at danger points.

ILLINOIS STATE ASSOCIATION REJUVENATED.

CHICAGO, Feb. 15.—The effort to rejuvenate the Illinois State Automobile Association has been successful, a new set of officers being elected and an active campaign planned. L. E. Meyers, of the Chicago Automobile Club, was re-elected president of the State associations, while George W. Ehrhart, of Decatur, was chosen first vice-president; R. A. Whitney, of Peoria, is the new second vice-president, and E. W. McCready, of Chicago, third vice-president. F. H. Trego, secretary of the Chicago Motor Club, will officiate in the same capacity in the State association, while John Farson will look after the finances. Directors chosen were A. J. Olson, Woodstock; R. H. Colby, Aurora; R. A. Baker, Springfield; W. H. Van Dervoort, Moline; J. C. Dickerman, Rockford; David Beecroft, E. Lewis Kuhns, Joseph F. Gunther and Sidney S. Gorham, Chicago.

Committees appointed were as follows: Revision of by-laws, F. H. Trego, E. W. McCready and S. S. Gorham; State reorganization, George W. Ehrhart, R. A. Whitney, R. A Baker, J. C. Dickerman and H. Tucker; trade affiliations, Henry Paulman, E. Q. Cordner, Edward Rowen and David Beecroft; finance, P. J. McKenna, W. Hildreth and H. Paulman. The work of the association for the coming year will be along the line of securing favorable legislation for motorists, co-operation in the improvement of the State roads, signboarding, the securing of discounts on motor car supplies for members and uniform laws for the central West.

HARTFORD CLUB TO HOLD SPRING RUN.

HARTFORD, CONN., Feb. 15.—Four stages of fifty miles each, making a total of 200 miles, will be the distance to be covered by the contestants in the endurance run which will be held by the Automobile Club of Hartford on May 22, with Hartford the starting and finishing point of each lap, and roads in various directions being chosen as the routes. This was decided at a meeting of the club when plans for the contest were brought up. The idea of having the competing cars pass through Hartford as many times as possible was a popular one.

The first lap will be from the start to New Britain, Meriden and Farmington back to Hartford, a route which will give the cars some climbing over the Southington Mountain. The second stage is to the east, over some rough roads, through Manchester, Hazardville and Windsor; the third is down the Connecticut Valley to Middletown, Portland, Glastonbury and back to Hartford. The final lap will take in Bloomfield, Granby, New Hartford, Canton and over the Talcott Mountain to the finish. There will be three classes for cars: Class A, for cars costing less than $1,500; Class B, for those costing from $1,500 to $3,000, and Class C, for those costing more than $3000. There will be cups for first and second place in each class.

Time penalties will be figured at one point for each minute lost, and gasoline engines must be kept running except at the noon control. Stops for tire trouble and for traffic will not cause penalties if motors are kept running, and the time will be added to the schedule by the observer. For any breakage or deformation of springs, spring hangers. frames or axles there will be a penalty of 60 points for each part.

SAVANNAHIANS TO DINE JACKSONVILLIANS.

SAVANNAH, GA., Feb. 15.—On Washington's Birthday the Savannah Automobile Club will give an oyster roast at King's Ferry. This place connects Savannah with Bryan county, and to it is one of the most beautiful roads in the State of Georgia. The Automobile Club of Jacksonville will be invited, and so will be Governor Hoke Smith and Governor-elect Joe Brown. From the Savannah club will be Frank C. Battey, R. M. Hull, Mayor George W. Tiedeman and Harvey Granger.

Governor Magoon Uses Franklin Car in Final Cuban Inspection.

White Plows White Snow.—The record-breaking snowfall in Milwaukee last week furnished ample opportunity for Milwaukee dealers to demonstrate the worth of the motor car as a winter vehicle. D. W. Stewart, manager of the White Co.'s Milwaukee branch, and the Hokanson Automobile Co., agents for the White Steam car at Madison, Wis., the state capital, took full advantage of the snow and pushed through drifts that horses and street cars could not buck. In Milwaukee a White steamer pulled the plow that cleared off the snow on all walks in the plant of the Schlitz Brewing Co. At Madison the White made a trip from the garage to the car barns of the street railway company without a hitch and while all street cars were tied up by drifts.

Far Western Drivers Will Climb Hills.—One of the greatest events of the year on the Pacific Coast is the annual Pasadena-Altadena hill climb. This will be held on Washington's birthday, which is a few weeks earlier than last year, the change being made on account of the rainy weather of previous years. Nine classes have been listed, differing as to price, and one special for the four fastest cars in the other nine events. The latter was won last year by Apperson in 1 min. 36¼ sec., and Edgar Apperson himself will be on hand to drive the "Jackrabbit" this year.

Want Oldest Electric.—Two prominent historical museums of this country are now endeavoring to secure from the Baker Motor Vehicle Company for permanent ownership, the Baker electric which has the honor of being the first of its kind built in this country. This car is wanted to add to collections of the first cars made, to contrast with those of the present time as showing the advance made in methods of road locomotion and it will undoubtedly be donated. This electric is said to be a fine type to contrast with the modern beautifully finished machines because of its century-old and general thrown-together appearance.

New Tire From Trenton.—The United and Globe Rubber Manufacturing Company, of Trenton, N. J., has gone into the field of automobile tire manufacturing with a pneumatic tire which will bear that name. A section of the firm's factory has been set apart for the necessary machinery, vulcanizers, etc. John S. Broughton, secretary and general manager, as well as Watson H. Linburg and Welling G. Sickel, other members of the firm, have had their cars equipped with experimental tires for some time to give them road tests and have found them to be highly satisfactory.

Pittsburg Buys a Pierce Arrow.—The city of Pittsburg is now the owner of an automobile. The purchase has just been made by the department of public safety, bureau of police, the choice being a Pierce-Arrow of 40 horsepower. It is the intention to use the car principally for riot and emergency calls. To that end dash cabinets have been arranged to carry revolvers and handcuffs, while heavy holsters, large enough to hold three high-power rifles, are attached to the back of the front seat. On the running boards are two large-size fire extinguishers.

The Goodrich Girl for 1909.—Adele is the Goodrich girl for 1909; "messenger, advocate, sweet persuader, reminder—and withal a rare, wistful, restful companion—just the sort for a man to take into his confidence," is the manner in which her sponsors describe her. Adele is the girl of the poster that the B. F. Goodrich Company, Akron, O., is sending out for the year 1909, in accordance with the now long-honored custom of this company. The Goodrich girl has become as famous as the Goodrich rubber products.

Trenton Dealers Organize.—Automobile tradesmen in the Jersey capital have organized the Trenton Automobile Dealers' Association with the following officers: President, R. C. Manning; vice-president, U. G. King, and secretary-treasurer, John L. Brock. A committee on automobile exhibit is composed of S. E. Kaufman, Walter Slack and Harry Stout. The coming show was taken up for discussion and this committee will have it in charge. Sixty cars are expected to be shown.

Packard Warehouse in Long Island City.—Extensive plans for a nine-story warehouse to be built in Long Island City for the Packard Motor Car Company of New York City, have been made by architects Albert Kahn and E. Wilby, of Detroit. The building will be used to relieve the congestion at the New York house, and in it will be room for storing cars for future delivery, repair shops, body building, and repairing departments.

Wagner-Field Company.—Automobile advertising and publicity handlers, has found larger quarters necessary to accommodate a growing business and staff and has moved into offices on the first floor of the Thoroughfare building at 1777 Broadway, New York City. G. M. Worth Colwell has joined the literary forces, and Burr Edwards Giffon, formerly with the Bates Adevertising Agency, has taken charge of the art department.

Change in Sales Methods.—The "Long-Arm" System Company, of Cleveland, announces that dating from February 15, 1909, the sale of its products will be conducted by the company direct. This change is made with a view to getting clearer business understanding and closer engineering touch with customers. Correspondence relating to all matters should be addressed direct to the company.

Studebaker Officers Unchanged.—The Studebaker Automobile Company at its annual meeting re-elected its present officers for the ensuing year. They are: Col. George M. Studebaker, president; Nelson J. Riley, vice-president; Clement Studebaker, Jr., secretary; Charles A. Carlisle, purchasing agent; Hayden Eames, Cleveland, general manager.

PERSONAL TRADE MENTION.

E. T. Birdsall has resumed his practice as a consulting engineer in New York City, opening offices at 41 West 63d street, and intends to make a specialty of the design and operation of commercial vehicles. He will also design gasoline engines for all purposes, make tests and appraisals. An automobile brokerage department has been opened for the benefit of prospective purchasers either of new or second-hand cars, expert advice being given. Mr. Birdsall has now had ten years of experience in the automobile manufacturing field and twenty-two in general engineering.

W. McKean White, formerly a Philadelphia automobile writer, has joined the editorial staff of THE AUTOMOBILE. Mr. White has been handling the automobile news for the *Evening Times* of Philadelphia since the Glidden Tour of 1908, previous to which for two years he had charge of similar work on the Philadelphia Press. Before entering the news field he was connected with the automobile trade in sales capacity, starting with Martin & Hart, at that time the Philadelphia agent for the Thomas and Cadillac in 1905, and later being with J. Hervey Nichols, the agent in Denver for the Winton and formerly the Oldsmobile.

Walter C. White at Show.—Walter C. White, the second vice-president of the White Company, in visiting the Chicago Show made his first appearance since his accident last spring at Cincinnati. Six months of residence in hospitals followed that, but he has fully recovered and is again in charge of the selling part of the White business. His arrival at the show was the beginning of an impromptu reception at the White exhibit.

Charles S. Monson has been secured by Gray and Davis of Amesbury, Mass., to act as western sales manager. Mr.

Monson has been the manager of the Detroit G. and J. Tire Company's branch for the past three years, previous to which he was with the Hartford Rubber Works for about four years and from 1893 to 1900 was salesman and superintendent of agencies for the Gormully & Jeffery Manufacturing Company.

A. R. Pardington, vice-president and general manager of the Long Island Motor Parkway, Inc., has accepted the chairmanship of the automobile committee of the Queensboro Bridge celebration, which is to take place during the week of June 12-18. An elaborate program of special interest to automobilists will be arranged, and a large attendance is already assured.

E. Roger Stearns, formerly manager of the Buffalo branch of the Ford Motor Company, has become assistant to N. A. Hawkins at the Detroit factory. Mr. Hawkins will assume many of the duties of vice-president James Couzens, who is going to do some pleasure traveling in this country and abroad during the next six months.

M. B. Leahy, formerly assistant manager of the Buffalo branch of the Ford Motor Company, has succeeded to the managership through the transferring to Detroit of E. Roger Stearns. Mr. Leahy's promotion comes in line with conscientious and faithful service and is well merited.

R. A. McNeilly, who has been connected with the Pope Manufacturing Company of Hartford, Conn., for the past five years, has resigned from that concern and in the future will be connected with the Boston branch of the Rambler Automobile Company.

Alfred Reeves, James Couzens and D. J. Post.—This trio left on Wednesday for a "rest" round of the Florida resorts, intending to go South as far as Miami and catch sharks and other denizens of the deep.

Edgar E. Mason, who has been connected with the Oakland, Cal., branch of the Auto Vehicle Company, has been appointed manager of the San Francisco branch of the Durocar Manufacturing Company.

George Jordan is now the manager of the Cameron branch in New York City, located at 231 West Fifty-fourth street.

DINNER GIVEN BY WOODS.

CHICAGO, Feb. 15.—On the top floor of its new factory, where a dining room and vaudeville stage had been installed, the Woods Motor Vehicle Company last Wednesday evening gave a dinner and entertainment to a number of the visiting tradesmen and press representatives. It was conveniently held after the show had closed for the evening and when artists from leading theaters could be present. Woods electric batteries furnished a brilliant illumination. Among those present were the following: H. S. Firestone and R. J. Firestone, president and sales manager, respectively, of the Firestone Tire and Rubber Company; H. Harmon, of the solid tire department of the Diamond Rubber Company; G. H. Atkins, manager of the Electric Storage Battery Company, and William Neath, engineer of the same concern; W. H. Mason and E. P. Rowan, of the Hartford Rubber Works; C. E. Whitney, of the Whitney Chain Company; Courtland Cramp, of the Cramp Shipbuilding Company; L. M. Wainwright, J. W. Sprag and W. P. Culver, of the Diamond Chain Company; C. F. Van Sicklen, William Shepard, H. A. Goddard, and representatives of the daily and trade papers.

GENERAL MOTORS SEEKS SITE.

LANSING, Mich., Feb. 15.—The General Motors Company, the recently formed New Jersey corporation, is seeking a location for a plant for the manufacture of gasoline engines. C. R. Hathway, of Detroit, treasurer of the company, has just addressed a letter to the Lansing Business Men's Association, asking for proposals and information regarding taxes, lighting, power, water and other facilities, stating that the company will need about 100 acres of land.

IN AND ABOUT THE AGENCIES.

Studebaker, Baltimore.—Dixon C. Walker, one of the best-known members of the Automobile Club of Maryland, has just closed a deal for the local agency of the Studebaker electric and gasoline cars. Following this up Mr. Walker leased, late Saturday afternoon from the American Ice Company, the site at 1917-19 North Charles street.

Goodyear, Boston.—So great has been the increase in the business handled by the Boston branch of the Goodyear Tire & Rubber Company that enlarged space has been necessary. This led to the purchase of a lot and the erection of a large five-story building, which has now been occupied.

American, Hartford, Conn.—R. D. & C. O. Britton have added the American roadster to their line now comprising the Maxwell and the Stoddard-Dayton. This is the first time that the western car has been represented in this city.

Peerless, Olds and Apperson, Pasadena, Cal.—Harry D. Pyle, of the Central Garage has announced that his firm has taken the agency in Pasadena for the Peerless, Apperson and Oldsmobile lines exclusively.

Babcock Electric, Rochester, N. Y.—A new firm known as the Gable-Hill Company has taken the agency for the Babcock electric carriages. They will also carry on a general repair and jobbing business.

Gaeth and Chalfante, Baltimore.—The Gaeth and Chalfante cars are being sold in this city by F. W. Sandruck, who has been given the agencies. Mr. Sandruck is located at 915 North Howard street.

Haynes, Evansville, Ind.—The local agency for the Haynes automobile has been taken by H. R. Fullenwider, in connection with the Richmond and Auburn cars, which he is now handling.

Mitchell, Newark.—The newest Newark news note is that the newly formed Martin Automobile Company will handle the Mitchell. The DeCamp garage has been taken over and will be refitted.

Reo, Baltimore.—The local agency for the Reo car has been placed with "Little Joe" Weisenfeld, the sporting goods man of this city. The Reo salesrooms are situated on Hanover street.

Chalmers-Detroit, Houston, Tex.—A new automobile firm, Burton & Johnson, has leased quarters at 812 Farnin street, and will have the agency for the Chalmers-Detroit car.

American, Trenton, N. J.—The American Motor Car Company of Indianapolis, Ind., has appointed J. Chauncey Van Horn local agent for the American line of cars.

Dinner on the Top Floor of the Woods Motor Vehicle Company's Factory, to Visiting Tradesmen and Pressmen.

Executive and Selling Force of the Excelsior Supply Company, Enjoying Dinner at Chicago Athletic Association.

Rambler, Dallas, Tex.—The Rambler Automobile Company has established Southern headquarters in Dallas, having built a three-story building at a cost of $75,000.

Kisselkar, Newark, N. J.—The Weldon & Bauer Company has taken the agency for the Kisselkar, which will be handled in this territory in connection with the National.

Rambler, Baltimore.—The Auto Equipment Company, Madison, near North avenue, announces that it has closed for the local agency of the Rambler car.

Maxwell and Stoddard-Dayton, Utica, N. Y.—The Oneida Square Motor Car Company has been appointed agents for the Maxwell and Stoddard-Dayton cars.

Pullman, Boston, Mass.—W. A. Shafer, proprietor of the Crown Motor Car Company, has taken the agency for the Pullman car.

Acme, Chicago.—The George L. Schofield Company has been appointed local agent for the Acme car, made in Reading, Pa.

Studebaker, Philadelphia.—E. Z. Stratton has just assumed charge of the Studebaker branch at 330 North Broad street.

Pullman, Trenton, N. J.—Harry J. Stout has taken the agency for the York, Pa., product in Trenton and vicinity.

Nadall, San Francisco.—The Phoenix Rubber Company has been appointed agent for the Nadall demountable tire.

FISK DINED ITS ARMY.

The Fisk Rubber Company gave during the Chicago show a banquet at the Auditorium Hotel to its agents and branch managers. A novel feature was a set of miniature Fisk bolted-on and removable tires constructed of candy. President H. T. Dunn presided, and the occasion was one long to be remembered.

MAXWELL-BRISCOE ENTERTAIN

The Maxwell-Briscoe Company entertained its army of agents during the Chicago show with a big banquet, which was well attended and at which Maxwell enthusiasm was rampant. Both Benjamin Briscoe and J. D. Maxwell addressed the dealers, and it was no fault of theirs if every man present did not understand the Maxwell car and the Maxwell policy before the end of the evening.

EXCELSIORS HAVE DINNER.

CHICAGO, Feb. 15.—Taking advantage of the presence at the Chicago show of the traveling representatives of the Excelsior Supply Company, F. C. Robie entertained the executive and sales forces of the company at a dinner at the Chicago Athletic Association. The local representatives were:

H. N. Kirk, sales manager of the auto-cycle department; C. C. Boynton, manager of the automobile supply department; F. B. Hart, manager advertising; H. W. Cooper, in charge of the retail selling branch, and F. W. Suter, C. H. McCormick, J. W. Grossmith, E. W. Doliver, H. H. Dewey, of the city sales force.

The traveling representatives present were: F. A. Skinner, of the Pacific Coast; Gideon Haynes, of the Rocky Mountain district; V. B. Mearns, of the "Corn Belt"; J. B. Morrow, of the "Corn Juice" districts, and Fred Wiel, Harry Svensgaard, F. Y. Horn and Jake Meyers, who between them cover the rest of the automobile world.

G. T. Briggs and N. A. Minister represented the factory sales corporation.

The dinner followed an enthusiastic meeting at which prices and policies for the coming year were discussed.

Maxwell-Briscoe Motor Company Dinner, Given at Auditorium Hotel, Chicago, to Maxwell Agents.

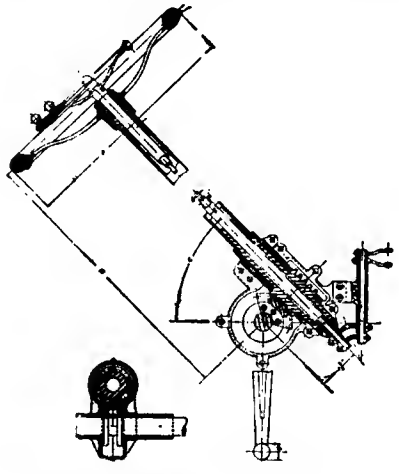
INFORMATION FOR AUTO USERS.

New Gilbert Specialties.—Two new specialties which will interest autoists because of their simplicity and utility are noticed in the advance catalog for 1909, just issued by the Gilbert Manufacturing Company, New Haven, Conn. One of these is the Gilbert pocket tool case, designed to fit flat in the hip pocket. The tools consist of a high-grade oxidized bicycle wrench, baby

GILBERT GAS TANK KEY AND BOTTLE OPENER.

screw driver and combination cutting pliers. The case is of neat design and made of chrome leather. The other article is a very convenient commodity—a gas tank key, with bottle opener attachment. It can be carried on a key ring, and either end is always ready for business. This specialty is furnished in malleable iron, with oxidized copper finish, or in bronze, nickel plated.

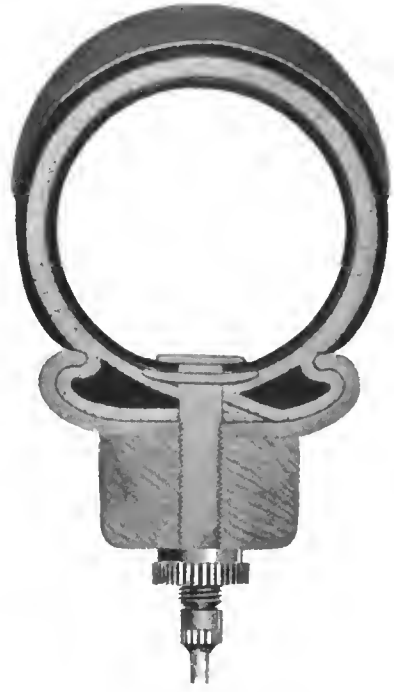
Gemmer Steering Gears.—During the coming season the Gemmer Manufacturing Company, Detroit, will produce a very largely increased number of its Model K steering gear, the details of which are shown by the accompanying illustration. This is of the worm and segment type, a ball-thrust bearing being placed above and below the worm to take all strain in the plane of its axis. The ratio is 5½ to 1, a quadruple thread, with a 2-inch lead, being employed, while the teeth of the sector are of 6 pitch. One complete turn of the hand wheel gives a throw of 65 degrees at the steering lever. Instead of being integral



MODEL K GEMMER STEERING GEAR.

with its support, the sector is made separately. All wearing parts are hardened and ground to an accurate fit, and, as a liberal amount of bearing surface has been allowed in every case, there should be little need for adjustment. The control levers are placed on the usual stationary sector over the wheel, the rods passing through the column and terminating in small bevels, meshing with similar pinions on an upright attached to the housing of the gear. This housing is cylindrical in form, and, as the gear is very compact, it takes very little room. The hand wheel consists of an aluminum spider carrying a mahogany rim, different diameter wheels being made to order. The Model K Gemmer steering gear has been specified on a number of well-known American cars for the coming season.

Simplicity the Keynote of Genesee Tires.—Prominent in the list of mechanical clincher tires which may be quickly removed and replaced in an emergency or otherwise is the Genesee. This tire, made by Thomas D. Buick Company, Flint, Mich., has a natural wedge lock which holds it very firmly in place when inflated. If the tire becomes deflated, on the other hand, so that this natural wedging effect would not obtain, it is still held by means of a



CROSS SECTION GENESEE TIRE.

mechanical lock, the valve of the inner tube passing through the wedge-shaped base of the shoe in such a manner as to form a perfect lock. The portion of the latter passing through the felloe is of an enlarged diameter, threaded. A nut pulls it down tight, this being milled for the fingers or pliers to grip upon. The wedging effect, previously spoken of, is obtained by parting the base of the tire, not as usual in the middle, but along a diagonal. Then, each side of the base, with its bead, runs out to a sharp point, when viewed in cross section. In position, these diagonally-parted ends overlap one another, and the inner tube as it is inflated presses upon the upper surface of them at the point of overlapping, thus forcing them apart and jamming them tightly into place against the clincher rim.

The entire absence of lugs, bolts, or anything else of this nature making as it does for simplicity, is an excellent feature. This is augmented by the manufacturers' guarantee, which extends over 5,000 miles of service. If there was any doubt in the user's mind, the latter feature should convince. This concern manufactures other automobile accessories, among which may be mentioned Mobilene sheet packing for packing all forms of joints, such as gear cases, crank cases, etc., and Genesee lubricating oil, Hi-Lo brand. This is a light-bodied oil for all the year use.

Joyce-Cridland Motor Truck Jack.—It comes as a sad shock to an autoist on the road to discover that no jack is at hand with which to take the weight off the car when it is necessary to do tire repairs. Or, if a jack is at hand and it is the kind which fails to satisfy, it is then

JOYCE-CRIDLAND MOTOR TRUCK JACK.

that the autoist will have to test his temper, and serve as a jack substitute. In view of the fair price at which a Joyce-Cridland can be purchased, it would seem as if the autoist who has to personally supplant an inferior jack becomes a "poor John." The Joyce-Cridland as here illustrated is a screw jack, and more, it has a high lift, and when it is all in it is short enough to stand under. Besides being a screw jack, which stands for ability, this jack is also of the quick return kind. The Joyce-Cridland jacks are made at Dayton, O., and handled in New York City by W. M. Briggs, at 136 Liberty street.

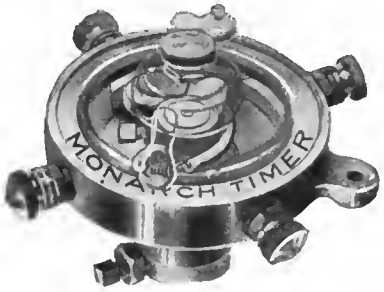
Swinging Coil for Curved Dash.—A coil made especially for use on low dashes with curved tops has been placed upon the market by W. H. Leland & Company, Worcester, Mass., the essen-

WORCESTER SWINGING SPARK COIL.

tial feature of which is its mounting. Swinging brackets are so arranged that they are not in evidence until needed, when the whole four-unit coil can be

swung forward and any units removed without disturbing the underneath wiring. On runabouts and other cars with low dashes this is valuable, while on all cars it can be used advisedly because when the coil box is pulled forward it exposes the commutator wire connections at the back. There is a concealed micrometer adjustment for varying the tension of the vibrator spring, which adjustment is independent of that of the platinum points and reduces the liability of excessive current consumption. The design of the coil is claimed to eliminate buckling and can be used in connection with magneto.

Benford's Monarch Timer.—This new timer, the product of the E. M. Benford Mfg. Co., Mt. Vernon, N. Y., is placed upon the market only after a long and severe test in actual service. It was developed by a practical, experienced mechanic, and its details and working parts are guaranteed by its makers to be absolutely correct and reliable and to be constructed of the best materials that can be found for the purpose. It is so designed that the electrical contacts, terminals and parts are not only well insulated, but they are sturdy. The shell is tight, sufficiently to assure that grease will stay in and dirt will not get in. The timing is precise because the means afforded are of a character to assure the very precision which is necessary to a motor of a plurality of cylinders.



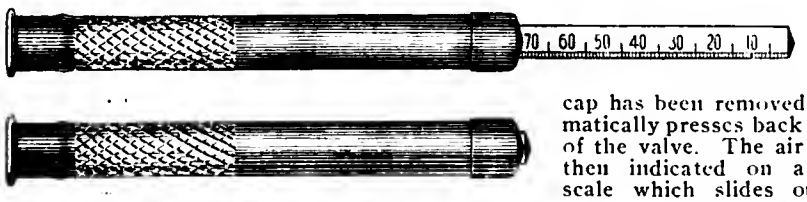
THE NEW MONARCH TIMER.

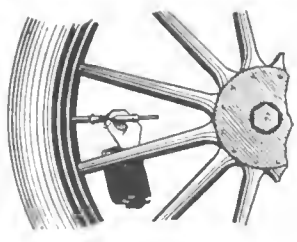
Connecticut Pocket Meter for 1909.—The Connecticut Telephone and Electric Co., Inc., of Meriden, Conn., has just placed on the market its new type 1909 dead-beat meter for testing batteries. These instruments have many improvements of note over the 1908 style. A new etched metal dial now replaces the paper card dial which is universally used for this purpose, and this dial is not only a handsome addition to the instrument, but adds greatly to its accuracy, also doing away with the common trouble of warping and bulging out, which causes the pointer to stick in taking a reading. The entire interior construction has been changed and is now made up on the deadbeat principle. A new type of pointer construction has also been added. The Connecticut Company is making a great many different styles of pocket battery

CONNECTICUT DEAD-BEAT METER.

meters. The volt ammeter is really two instruments in one, the voltage side being used for testing storage batteries, each cell of which should be tested individually, and should show 2.5 volts after the battery is fully charged and still charging. If they show less than 1.7 volts they should be recharged. A storage battery on open circuit when fully charged should show between 2 and 2.2 volts. The ampere side is used for testing the condition of dry batteries, each cell of which should be tested separately, and if any cell shows less than 6 amperes it should be replaced with a new one. This new type of instrument is a worthy addition to the already large line of high-grade Connecticut products.

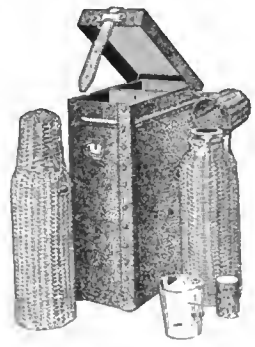
Twitchell Tire Gauge.—A tire gauge, which is only three and a half inches long, can be carried in the vest pocket and applied at any time, will be a welcome innovation to many automobilists who have been suffering from tire trouble due to insufficient inflation. This description applies to the Twitchell gauge, the invention of C. R. Twitchell, of Los Angeles, Cal., and perfected and controlled by the W. D. Newerf Company, of the same city. The gauge is designed to screw on the valve of the tire, after the cap has been removed; this automatically presses back the plunger of the valve. The air pressure is then indicated on a graduated scale which slides out through the other end of the gauge. Ordinarily the automobile user guesses at his tire pressure, and almost invariably the pressure is too low. His tires, time and patience, also his pocketbook, suffer accordingly. The illustration shows the Twitchell gauge closed, extended and applied to a tire. It can be applied in two seconds and the registration is instantaneous, and guaranteed by the makers to be correct. The W. D. Newerf Rubber Company is arranging to put the Twitchell gauge on the market all over the country from coast to coast.





TWITCHELL TIRE GAUGE, OPEN, SHUT, AND APPLIED.

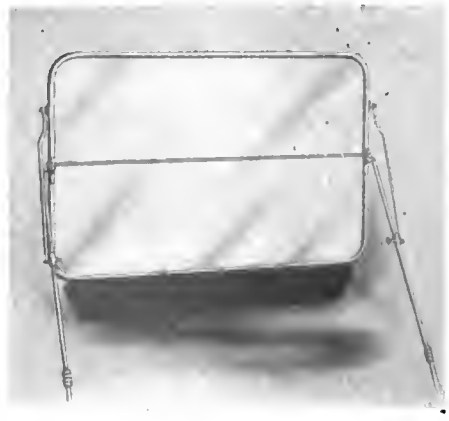
Many Styles of Caloris Bottles.—The great demand for the Caloris bottles which will keep liquids cold in the hottest weather, or hot in the coldest days, without the use of heat or fire, has become so large that the Caloris Manufacturing Company, of Philadelphia, is now putting upon the market several styles of bottles. In addition to those covered with metal and those covered by wicker, a new type of leather covered bottles is being sold known as the "Sterilo" Caloris bottle. This one is arranged so that the glass bottle can be taken from its case and be sterilized, a feature which is very important when used in connection with sickness. Inasmuch as the case is well padded, however, it is also useful where handled very roughly.



CALORIS BOTTLES AND CASE.

There has been perhaps no invention in recent years which has proven such a boon to tourists and others who are out of doors very much or are away from places where hot or cold refreshments may be obtained. Motoring is one of these enjoyments where such is the case, and it is rather seldom now that a party goes upon a long tour without a Caloris equipment. In leather cases two or more bottles can be carried at the same time with as many different liquids. In the new metal covered bottles the bottom is detachable, so that it, too, can be easily taken apart for cleaning, while a spring bowl and leather cushion protect the glass from possible breakage.

Lincoln Folding Wind Shield.—The Bi-Motor Equipment Company, 177 Portland street, Boston, has brought out an attractive line of wind shields under this name. They are made of French plate glass, set in polished brass tubing, with mahogany baseboards. The folding device is claimed to be "so simple that a child can operate it." The shield is guaranteed in every particular, and will fit any make of car. The same company also makes, at a slightly higher price, the "Portland" divided drop shield.



LINCOLN FOLDING WIND SHIELD.

Vol. XX New York—Thursday, February 25, 1909—Chicago No. 8

THE AUTOMOBILE

Through the Heart of ITALY

By Francis Milfoun

MANY an automobile tourist begins his Italian round at Naples, after having debarked his automobile at that port. A bee-line north covers the best and most characteristic Italian itinerary, and a detour here and there, as from Naples to Amalfi, from Rome to Subiaco, from Florence to Vallambrossa, and from Padua to Mestre, for Venice, gives quite all the variety that the hurried traveler usually has time for. It is not knowing Italy down to the ground, but one finishes the round with a nodding acquaintance with many things he hitherto knew not of. This is particularly true if the journey is completed—so far as Italy is concerned—by the crossing of the region of the Italian lakes and entering Switzerland over the Simplon, or France by Mont Cenis or the Petit Saint Bernard.

The detour from Naples south to Sorrento, Amalfi and Salerno, via Torre del Greco and Castellamare, is over about the only deservedly good road in south Italy, and even it is sadly cut up, dusty and stony, depending largely upon the season of the year as to its goodness or badness. A hundred and fifty kilometers out and back covers the distance, and the itinerary embraces the most romantic and historic succession of kilometers in all Italy.

Herculaneum, Pompeii, Sorrento, a boat ride to Capri, and then Amalfi and Salerno can all be done in a day by the owner of a swift automobile—that is, provided he does not want to spend a week or a month on the same trip. Lunch may best be taken en route where fancy wills, Pompeii will be too early and Amalfi too late; Sorrento will, perhaps, be the most likely place to take refreshment, say the Hotel Vittorio.

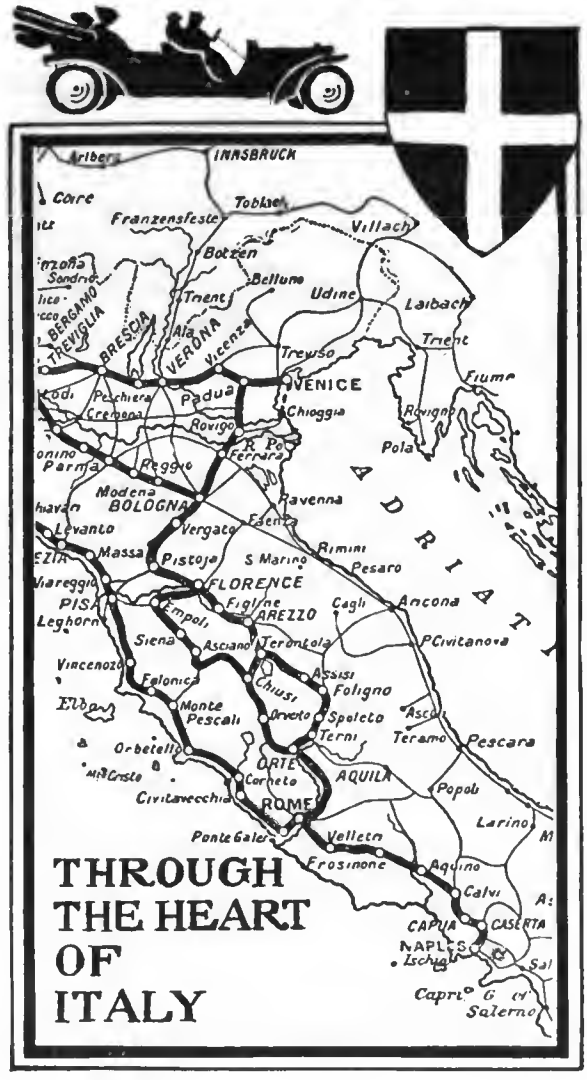
The road from Naples north to Rome follows the old Appian Way from Capua to the Eternal City. Straight through the Campagna runs the old Roman highway, due in the first instance to the genius and energy of Appius Claudius. It is not a "good road," as we who know the "good roads" of France will recognize, but it is direct and fairly flat for the whole 227 kilometers of its length, though not by any means does it pass through the most idyllic and attractive part of the Italian countryside.

Caserto and its Palazzo Reale, Capua with its memories of its fall to Hannibal, Cassino with its Monte, its Rocca and its Amphitheater, and Valmontone and Ceprano are the chief places of interest en route until one comes up with the Alban Hills and suburban Rome itself. There are two alternatives to the direct road from Naples to Rome. One follows the coast line as near as may be, a poor, mean road, but interesting because of the unexploited little towns through which it passes; the other branches off from the Appian Way at Frosinone, eighty kilometers before Rome is reached, and enters the capital via Subiaco and Tivoli.

Bologna's Picturesque Skyscraper.

To any one with a liking for the unconventional, the latter road especially is recommended. We did it, and were the happier for it, though we had never heard of any other automobilist who had made the detour, perhaps thirty kilometers more than by the direct road. This is the charm of Italy—to get away from the heaten track and the crowds of convention and every day humdrum.

The road from Frosinone to Subiaco rises from 180 meters to 958 meters in twenty kilometers, but the average of the grade is slight. From Frosinone to Rome the direct road runs at a normal



elevation of 250 meters. At Subiaco is a country inn which must be a near relative, in point of age, with the castle on the height above its rooftop. It is called "La Pernice"—"The Partridge"—and is typical of its class throughout central Italy, though in no sense an up-to-date tourist establishment, but much better than anything of a similar order in England or America. We have to come to these effete lands like Italy and France and Spain for some things; how to cook a chicken and make a salad, for instance.

The proprietor and the cook at Subiaco's "La Pernice" have learned their business and practice it well. The marvel is that they were able to learn anything in such a dull place as this little hill-town of mid-Italy. Four or five francs a day buys the best the inn has. What could one want more? It is said the Subiaco's inns used to have a flat rate of two and a half francs a day all in, but that happy time has passed. In the trail of the artist folk who originally exploited Subiaco now come occasional tourists by rail and road, and again by automobile, in twos, sixes and dozens in a day. And prices are soaring upwards—for the automobilist, at any rate; if you are an artist, the magic of your white umbrella gains you a very substantial discount off regular charges. Even the Italian landlord has an eye for business, if he has no business system. He is no robber, though; he leaves that to his smiling servants, with their everlasting itching palm which calls loudly *buona mano* whenever one is in sight.

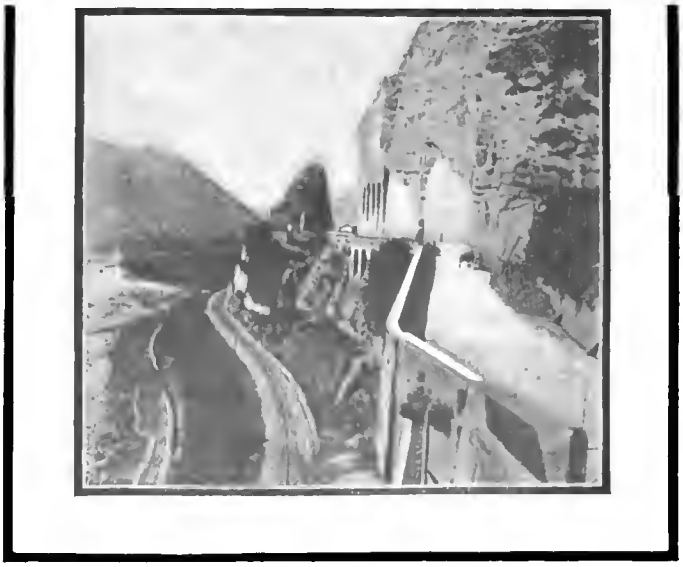
All the attractions of "La Pernice" are on the table; the table itself, the chairs and even the crockery would hardly pass muster on an emigrant ship.

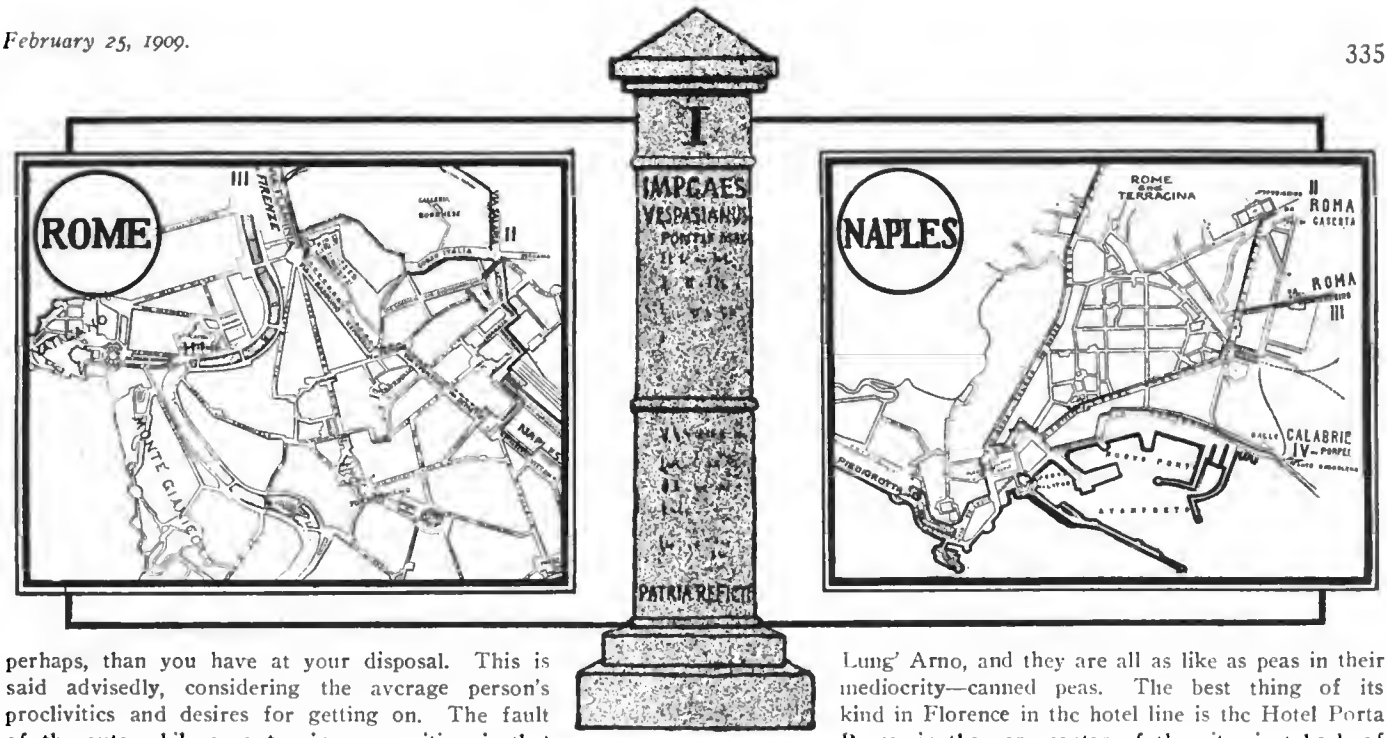
The art gallery of "La Pernice," the sketches left behind by several generations of artists, is a thing to see and marvel at. The works of art are beyond price; indeed, they are the lodestones which draw trade to the padrone's *tavola rotunda*. Some day, perhaps, art nouveau ideas will take root and branch under this modest roof tree, and then your arrival will be telegraphed to the journals of Rome and Paris as "en passage à la Pernice"—and then prices will go still higher—and then the partridge might as well be killed; it will die an early death soon after.

From Subiaco to Rome via Tivoli is an easy afternoon run. Rome is all things to all men and women, but it is nothing much for the automobilist, save for an excursion out on the Campagna, past the Circus, the Tombs and the ruins of the Aqueduct. Beyond this there is little for your chauffeur to occupy himself with while you are doing the guide book round save to hang around the nearest café and drink *"paleale"* and *"wheesky"* with others of his kind. All drink-purveying establishments in the stranger's Rome sell these liquids, though of dubious brands and invariably at outrageous prices. A chauffeur is a nuisance anyway; he is doubly so at Rome. The only thing he can interpret is the bill of fare; you have to count up his washing for him when it comes home from the laundry, and like as not he will make you pay for the pieces that have been lost. After Rome, a day, a week or a lifetime, you take the road again, north across Etruria via the Viae Aurelia.

The choice of roads from Rome to Florence is bewildering. You may go by Terni, Spoleto and Perugia, or by Viterbo, Orvieto and Siena, or by half a dozen other routes, each appealing in its own special way. You may not do all of them, though, without quadrupling the time necessary for one, more,

ORVIETO—LA PORETTA





Rome's Golden Milestone.

perhaps, than you have at your disposal. This is said advisedly, considering the average person's proclivities and desires for getting on. The fault of the automobile as a touring proposition is that its capabilities are so great that it has got us all hypnotized into doing a hundred, two hundred, five hundred kilometers in a day, when we should be better off by far if we did half that, or even less.

Three days in Italy, from Naples to Como, and then Switzerland, has been too often the itinerary of the hurried traveler. Naples-Rome and Rome-Florence, then, are bound to be covered at full speed and on a bee-line. What matters it that San Giminano and its towers lie but a dozen kilometers off the main road from Siena to Florence? One lunched at Rome; he must dine at Florence, and only stop at Siena because of the need of filling his tanks with benzina.

Three hundred kilometers between Rome and Florence have been done before now between meals. One had much better make two days of it and, above all, stop at Viterbo, Orvieto, Siena, San Giminano and Volterra. The hills will pull your speed down some, anyway. The country north from Rome is not as flat as was the Campagna. There is one bit, at Radicofani, between Siena and Viterbo, that rises four hundred and fifty meters in nine kilometers, and another just below Viterbo which takes a flight of five hundred meters in air in ten kilometers.

If one comes north via Perugia he will remember that city as well for its hotel as for its "sights." The chief rest house for travelers at Perugia is the Grand Palace Hotel. Its name lately anglicized. It has been considerably improved, doubtless, since the seventies of the last century, when a traveler wrote that in spite of the fact that it had one day sheltered sovereigns, popes, cardinals and princes, it was an unlovely and incapable establishment indeed. Now it is truly enough an up-to-date hotel—as nearly up to date as an Italian hotel can be in a city of twenty thousand inhabitants. It has a garage, the pleasing custom of serving *vin comptis* at table d'hote (this even if you be an inexperienced traveler in Italy) and of further allowing you a discount of ten per cent. for having bestowed your patronage upon it, though for this you have to give proof of your adherence to either the French or Italian Touring Clubs.

So much, then, for the changes which are coming to pass in Italy. They were needed, doubtless, but come they have, and are still coming. The automobile has done it.

Florence, in good weather, is easy getting in and out of; in bad weather it's a slough. The shady groves of Vallambrossa are at its doors and Fiesole nearer still. Each is a classic excursion to be made while at Florence. Hotels at Florence are of the tourist kind and unappealing from most, if not all, points of view. There is a whole battery of them along the Lung' Arno, and they are all as like as peas in their mediocrity—canned peas. The best thing of its kind in Florence in the hotel line is the Hotel Porta Rossa, in the very center of the city, just back of the Strozzi Palace. It is a sleepy, rambling, dingy old hotel, but not unclean, and the food is remarkably good, though remarkably Italian. This is one of the things that one comes to Italy for, or ought to be. You lodge your automobile in the stable with the railway bus and its equines for a franc a night. The other hotels chiefly haven't garages, and that of the F.I.A.T. concern is a mile away from the center of things.

To Bologna via La Futa Pass is 102 kilometers. The road lies through the heart of Tuscany, and is accordingly lovely, but considerably less so than that via Prato, Pistoja and the Pass of La Poretta. The latter lengthens the route by twenty odd kilometers, but is the easier, as fifty kilometers of the direct road run up hill.

All through this region one eats and drinks of the best of country fare, with nothing imitative of England, France or Germany, as in the cities and big towns. If a simple lunch of bread and cheese and salad and good Chianti is wanted, any wayside *osteria* will give you as good as any palace hotel in existence, no matter what may be the difference in price. One perforce, too, has to be content with this occasionally in Italy, if unforeseen circumstances keep him longer en route than he anticipated once and again.

On one occasion we were in just that position, and spent eighteen hours at Barberino di Mugello and fared well indeed at the Scudi di Francia, though the village is not marked on many maps and in no guide books we had ever seen. We just

happened there by chance, and stopped long enough to lift off a cylinder and put it back again—nothing serious, though it looked bad at first. The local blacksmith lent his aid for the best part of six hours for two francs, and the drug store supplied the *benzina* the next morning to speed us on our way.

Bologna was reached at dusk through the frowning Porta Saragossa, and following a long line of tram track over interminable kilometers via "Greater Bologna." Bologna has a couple of skyscrapers which would put New York's Flatiron Building to shame were they side by side. The photograph tells the story.

From Bologna to Ferrara is forty-six kilometers of straight, flat, uninteresting roadway. In sunlight its esthetic qualities improve, but all the same to Ferrara, and to Padua, seventy-five kilometers beyond, it is hardly more than a dyke road running between swamps and morasses, a land half aquatic and half terrestrial, wrenched from the very sea itself ages ago.

Ferrara should be made a stopping place for the sake of contemplating its old castello, where the beauty and gayety-loving court of the d'Estes dominated the whole esthetic life of Italy in Renaissance days. You can take the opportunity, too, of lunching at the Albergo Europa, which is very, very good indeed—and they will make no distinction as to price or fare whether you come on foot or in a "Sixty," say half a dollar. *vino compresso.*

If you *will* rush things, and won't stop at Ferrara, you may skip it by passing the Strada di Circonvallazione, joining up with the Padua road on the other side of the city. You are grateful for this, knowing that you have avoided the busy traffic of the center and the possibility of losing an hour.

Almost immediately after Ferrara, perhaps three kilometers beyond, you come to the little town of Portelagascoro and plunge precipitately, almost before you realize it, into the midst of a great market house or *loggia* of some sort. You inquire for the Strada di Padova, and they tell you that this is it. You keep on through this gloomy tunnel of a street for a hundred meters or more, when suddenly the sharpest right-angled turn you ever met with is directly before you. It descends like the side of a house, a slimy, muddy, ill-kept back alley of a road—really the Strada di grande Communicazione of these parts. It now takes an even stiffer plunge and crosses a bridge of boats over the Po. Keep your wits about you just after leaving Ferrara, or you will meet with an untimely death, and there will not be enough left of your automobile to pay for fishing it out of the river and ship back home for your heirs to quarrel over.

Rovigo, Este and Monselice are passed in turn just north of Ferrara, and the landscape aspect improves in quality and appeal, though still all is flat and miasmatic. Padua is lovely from all points of view, and the entrance is monumentally fine. The Albergo Stella d'Oro has all needful accommodation for men, women and automobiles. One eats well in the *ristorante*, but the Italian officer at the next table eats bètter. He knows what to order and you don't. He gets the best and most characteristic fare and you get poor imitations of the roast beef of old England and a thin watery soup when what you wanted was spaghetti, ravioli and a coteletto di vitello.

It is 38 kilometers to Venice, or rather Mestre, a place of 10,000 inhabitants, great railway affairs and innumerable automobile garages. Of the latter the Auto-Garage Internazional is perhaps the best. You may not approach Venice in your automobile nearer than Mestre. From there you may take the train over the stone arches of the six-kilometer bridge, or better still, hire a gondola for a dollar at the very door of your garage and make your entry to the City of the Lagoons in that fashion.

From Mestre to Vienna one's road lies via Udine, Pontebba-Villach and the Semmering Pass, between 500 and 600 kilometers. To Innsbruck via Cadore-Tolbac and the Brenner Pass it is about 300 kilometers. Westward through the Italian Lakes and to Switzerland via the Simplon or the Saint Gotthard is approximately 500 kilometers and to France via Susa and the Petit Saint Bernard or via Susa and Mont Cenis, say, 600 kilometers.

PARIS, Feb. 20.—Boulogne-sur-Mer has been fixed upon as the scene of the French voiturette race, the only pure-speed contest to be held in France this year. A triangular course, bearing a very strong resemblance to that of Dieppe, but only measuring 25 miles round, has been selected on account of its varied nature, comprising excellent straightaways and grades that the little cars will not be able to rush. Starting from the outskirts of the town, high up on the cliffs overlooking the sea, the cars will run first of all over an ondulating national road of excellent surface and having a straightaway of nearly seven miles, where the highest possible speeds can be attained. At the end of the first triangle the cars will have to make a sharp turn through the village of Alinethun, the run to Desvres being over a very winding road. At Desvres a sharp turn to the right, followed by an easier one to the left, then an abrupt grade of 12 to 13 per cent., that will call for the use of a low gear and all the power that the engine can develop. From Desvres to Bainethun there is a succession of switchbacks of a very accentuated nature, all of which can be tackled without great difficulty by reason of the great impetus gained on the descent. Three miles before the Boulogne corner of the course there is a mile hill with a grade of 9 per cent. that will severely test the cars, for, owing to a turn at the bottom, it will be necessary to climb it from a standing start.

The race, which will be run on Sunday, June 20, promises to have about 60 starters, among them being a greater proportion of foreigners than ever before.

France will be represented by Sizaire-Naudin, Delage, Peugeot, Alcyon and other less known makes.

England, which has never before taken part in a voiturette race, has promised to send over a formidable group, comprising Humber, Vulcan, Adams, Star, B.S.A. and N.S.U.

Austria will put in three Laurin-Klement cars.

Germany will send three Adler and three N.A.I.

Switzerland will provide a Martini team.

Italy will bring forth three of Lancia's small cars and a team of Isotta-Fraschinis.

There is every probability of America being represented in the race.

National colors are: America, white body, red chassis; France, blue; German, white; England, red; Italy, green; Belgium, yellow; Switzerland, yellow body, blue chassis.

The modification in the rules regarding cylinder area is doubtless responsible for the increased foreign entries. Formerly bore was limited and stroke left unfettered. This produced an exceptionally long stroke engine, last year's single-cylinder winner having a bore of 3.9 inches and a stroke of 9 4/5 inches. It is now considered that the efficiency of a long stroke engine has been fully demonstrated, no technicien being found to maintain that engines of equal bore, but varying in stroke, are of the same power. Thus, though the long stroke is still encouraged, bore is not rigorously limited.

For a single-cylinder engine it is permitted to increase the bore above 100 millimeters (3.94 inches) to a maximum of 120 (4.72 inches) on condition that the stroke is decreased in proportion. Starting from 100 by 250 (3.94 by 9.84) bore and stroke, the former may be increased to 120 (4.72) on condition that the latter is decreased to 120 millimeters, the stroke being stipulated for each millimeter bore from 100 to 120. The same applies to multiple cylinder engines.

FRANCE HAS 43,550 AUTOS IN USE.

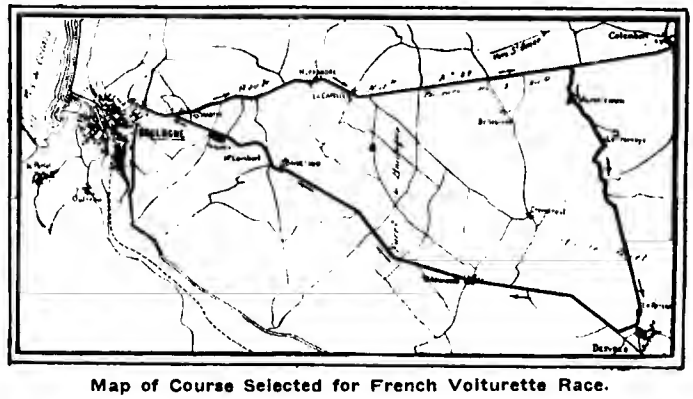
PARIS, Feb. 20.—France possesses a total of 43,550 automobiles in active service. The number seems small compared with the 83,000 claimed to exist in England, but from this latter figure a considerable deduction should be made for double declaration owing to change of ownership. The French figures are obtained from the annual declarations of owners for taxation purposes. Cars in course of manufacture, in stock ready for sale, out of service through old age or accident, are naturally not declared by their respective owners, for declaration means taxation. Thus the French figures, taken on February 1, 1909, apply only to cars on the road or ready to be put on the road, and totally exclude double declarations.

Paris is responsible for 7,400 automobiles, and in this respect is a long way ahead of any other city in France. The rest of the Department of the Seine claims 1,950 automobiles, and is followed by the Rhone district, comprising the manufacturing city of Lyons, with 1,765 autos. Other districts having more than a thousand automobiles are Alpes Maritimes, Bouches du Rhone, North, Rhone and Seine et Oise. Corsica is at the end of the list with only 10 automobiles. Motorcycles are not included.

FRANCE TO TEST SMALL COMMERCIAL CARS.

PARIS, Feb. 18.—Small commercial vehicles will be put to the test over the rough roads in the neighborhood of Paris from April 22 to 30. The test, which is a repetition of the one held last October, is provided for the lighter type of delivery automobiles, taxicabs, hotel and station omnibuses and motorcycles with a luggage carrying capacity. The distinctive feature of the trial is the use of various fuels, comprising gasoline, White Spirit, carbureted alcohol and benzol. As the same course is followed on each of the eight days devoted to running, it will be possible to make close comparisons between the relative cost and efficiency of the different fuels, as well as comparisons between the vehicles using them. Regularity of running is essential to qualify, but the basis of classification will be economy in fuel and lubricating oil. The total distance to be covered is about 100 miles a day.

All the patents, models and manufacturing rights of the Voisin aeroplanes at Paris-Billancourt have been acquired by August Euler, of Frankfort-on-the-Main, who will erect a factory on a very large scale in that city.



Map of Course Selected for French Voiturette Race.

Motoring Aloft Continues to Develop

PAU, FRANCE, Feb. 20.—The work of training pupils to handle the Wright aeroplane has begun on the Long Pont aerodrome, on the outskirts of the city. Wilbur Wright, in accordance with his usual custom, first flew over the ground alone at a very low altitude, made a further flight at an increased height, then took his pupil, Paul Tissandier, for a short skimming trip. The contract calls for three pilots trained to handle the machine perfectly, the three men chosen being Paul Tissandier, Comte de Lambert, and Ernest Zens. There are a number of others, however, who have given orders for Wright machines and are anxious to be trained by the American pilot.

Wright declares that the ground at Pau is perfection. Even at this time of the year there is very little wind, and with an open plain extending for nearly thirty miles, it should be possible to make some record flights. Wilbur Wright, however, is more anxious to finish his work in France than to make further experiments, and it is doubtful if he will for the present attempt more than the training of his pupils. It is now absolutely certain that Wilbur Wright will not attempt to win the Monaco prize of $15,000, though two of his machines may be entered for the event before the end of March. M. Michel Clémenceau, the selling agent of the French syndicate formed to exploit the Wright patents in France, states that he will have two machines ready in time, and that Comte de Lambert will pilot one, and that he will steer the other himself. It remains to be seen whether two men who have never yet driven an aeroplane can become sufficiently expert in one month to make the flight across the four miles of water as required by the Monaco rules. If this can be done it will be a distinct triumph for the Wright system, for it will prove that the superiority is in the machine, and not in a specially skilled pilot.

Fournier's Début in Aeronautics.

PARIS, Feb. 20.—Henry Fournier, ex-racing cyclist, motorcyclist, and automobile-race driver, with the winning of Paris-Bordeaux and Paris-Berlin among his records, has now joined the ranks of the aeronauts. Flying machine "Henry Fournier No. 1" has just received its last coat of varnish and is waiting for its power plant at the Voisin Frères factory, near Paris. It is a biplane type of machine, in all essentials similar to the one handled by Henry Farman and Delagrange last year. Fournier, who is looking after the power plant himself, intends to fit a four-cylinder Itala motor developing not less than 50 horsepower, and only differing from those used on cars by a little paring away of unnecessary metal. It is his opinion that better results can be obtained by a reliable and comparatively heavy type of engine than by a featherweight mechanism only fit for short spells of power producing.

Henry Fournier has just left Paris for Turin, to be present at the final test on the bench of his aeronautical engine. If this is satisfactory it will be fitted to the aeroplane at once and trial flights made within a few days. If everything works satisfactorily, Fournier intends to compete for the Monaco prize, the last date for which is March 24. Should, however, his apprenticeship in the flying school not be completed by this time, it is his intention to fit himself and the machine for all the most important flying-machine races to be held in Europe this year, including the Gordon Bennett race, the Aero Club Grand Prix, and the Rheims carnival.

Unlike the Farman aeroplane, the Fournier flyer will not have its propeller mounted direct on the engine shaft, but will make use of a reducing gear, which will give a propeller speed of about 1,000 revolutions a minute. The weight of the motor, complete with oil, water and all accessories, will not be less than 440 pounds. Fournier himself is decidedly a heavyweight compared with Farman, Wright, Delagrange, and Santos-Dumont, and now turns the scale at 207 pounds. Thus when the biplane leaves the ground it will doubtless have the record of weight lifting. Fournier is convinced that his own weight and that of his engine will not hinder him from making long flights.

Farman to Build for Himself.

PARIS, Feb. 20.—After flying for nearly two years with machines of other men's construction, Henry Farman has decided to build for himself, and according to his own ideas. Two aeroplanes are now on the stocks, one of them being a biplane in which the principal modification is an increase of the distance between the bearing surfaces from 58 to 78 inches, with a view to obtaining greater sustaining power. The front elevation plane will be thrown out a little further than usual, and will be made larger in order to give more power. Winglets may be fitted, and the rear planes may be built with flexing tips. If this is done, the rear rudder will be abolished. The second aeroplane will be of an entirely different type, the forward equalizer being abolished, and the wing tips made flexible as in the Wright machine. The rear bearing surfaces will be cellular, as on the present machine, but will have a variable inclination at the will of the operator. Farman has completed arrangements for a number of these machines.

Rheims to Have Aeroplane Meet.

PARIS, Feb. 20.—Rheims, the old cathedral city in the East, has become enthusiastic over the aeroplane, since Henry Farman fluttered down on its outskirts, and now announces an aeronautical week for the last days of August, or the opening days of September. The old city, in addition to its famed cathedral and champagne cellars, possesses vast plains all around it, the extent of which can be gathered from the fact that in 1901 a review of 150,000 troops was held before the Czar of Russia and masses of spectators. It is on this land, known as the Bethany plain, that it is intended to hold the aeroplane races with a minimum prize list of $30,000.

There will be separate classes for big-bearing surface, slow-speed flyers of the multiplane-plan type, and for high-speed monoplanes, each type being tested for speed and endurance, for high flying, and for performances with passengers on board. The local committee responsible for the raising of funds to hold the races, has secured the co-operation of the Mixed Aerial Commission—a body composed of members of the Aero and Automobile Clubs of France and of the National Aerial League—and will doubtles produce really competitive events. The races will be within the reach of all the leading aeroplanists, the committee being more anxious to obtain twenty machines, each capable of flying ten miles, than a single aeroplane with an ability to cover 100 miles. Thus unlike some of the aeroplane "races" projected in France, and which are in reality disguised publicity schemes, there should be real sport at Rheims.

By the end of August at least twenty Wright machines should be in the hands of capable pilots; thus although the American pilot himself may not be there, an opportunity will be afforded of matching this type of machine against the best that France can produce. This alone should be sufficient to draw enormous crowds of spectators. The nature of the ground will allow a course about eight miles.

TREND IN TRANSMISSION PRACTICE

By Thos. J. Fay

Chapter IV

IN automobile work diametral pitch of teeth, as used, ranges between 4 and 10, as 4, 6, 8 and 10; it is not usual to adapt the odd numbers as 5, 7 and 9, although 5 pitch is used to some extent. Above 8 pitch, it is rarely that the teeth are used, exccpting in planetary gearsets, when 8 pitch abounds to quite somc cxtent. In sliding-gcar scts 6 pitch is the most used, and that this is a good selection is assured, on the ground that the strength is adequate for the purpose, and the teeth do not make a noise excepting in the cases in which the pitch-line velocity in feet per minute is abovc 1000.

Relation of Diametral to Circular Pitch.

Diametral Pitch.	Circular Pitch.
4	.785
6	.524
8	.393
10	.314

For other concrcte dimcnsions the formula is as follows:

$$(1)\ \text{Circular pitch} = \frac{\pi \times \text{pitch diameter}}{\text{number of teeth}} = \frac{\pi}{\text{diametral pitch}}$$

$$(2)\ \text{Diametral pitch} = \frac{\text{number of teeth}}{\text{pitch diameter}} = \frac{\pi}{\text{circular pitch}}$$

$$(3)\ \text{Pitch diameter} = \frac{\text{number of teeth}}{\text{diametral pitch}}$$

If internal gears are to be used, it will be well to remember that "doctoring" will be avoided if the pinion has less teeth than the internal gear by at least twelve. In all gear work it is much to the point to avoid undercutting, which is a matter of using enough teeth in the pinion. As a general rule it is not considered good practice to use less than 14 teeth in the low-gcar pinion of a transmission gear set. There is one other point which will save the embryo designer sleepless nights, *i. e.*, in planctary work, if there is a sun and planet in one radial plane, all gears must have an even number of teeth.

In the selection of gears, which becomes a nccessity, in order to establish a suitable ratio between the motor and the road wheels, it is generally possible to fix upon such a number of teeth as to avoid fractional dimensions of the pitch diameter. This is not a grave necessity, yet even so it is just as well to have even relations, in possible cases.

As to the width of teeth, little can be said by way of establishing a standard. All the attempts at fixing upon the width (face of gear) has led to nothing thus far, largely because the practice has failed to demonstrate that "rock-bottom" has been reached, either as respects the quality of material or the life in service, under well-defined conditions. In some cascs gears have been made for automobile gearsets less than ½-inch face, for 6 pitch, as the greatest width, using a 30-horsepower motor, in cars of the touring class. These gears served very well indeed, and in other cases with gears 2 inches face, the life was short.

That hard material must be used if the facc is narrow seems to be good reasoning; on the other hand, it is generally considered that the teeth do not contact all along the face, and if this is so, what is the gain if the facc is wide? That thcre is a gain if the "flywheel effect" is kept down is assured, and it does seem as if the life of narrow-faced gears is, on the whole, better than if the facc is wide. The average designer adapts

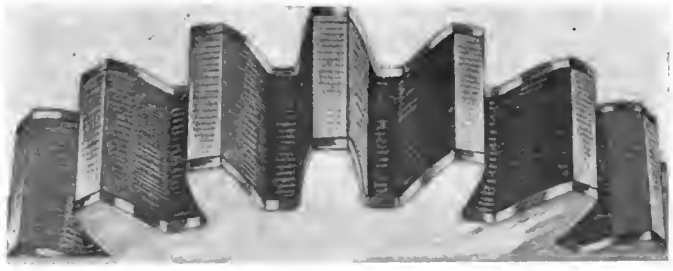


Fig. 18—Example of rawhide, shrouded involute teeth gear.

what he calls a happy medium, and in doing so shows lack of originality on the one hand, and a certain conservatism on the other.

That the old practice of machine designers bears any relation to the true situation, is not believed, unless cast-iron gears are used for the purpose, and it is assured that they would fail in automobile service, just as would gears of fine material fail, were the old methods of design (cast-iron methods) coupled with good material; in the later case the failure would be due to "inertia" rather than to the inferior material.

Proportions of Teeth of Gear Wheels.

This is a phase of the subject which has been the mark for designers for many years. The present trend is in favor of values as follows:

P = diametral pitch in these cases.

(4)	Whole depth of tooth	= 2.157 | P
(5)	Addendum (depth of tooth above pitch line)	= 1 | P
(6)	Working depth of tooth	= 2 | P
(7)	Dedendum (depth of tooth below pitch line)	= 1.157 | P
(8)	Clearance at root	= 0.157 | P
(9)	Thickness of tooth	= 1.57 | P
(10)	Width of space	= 1.63 | P
(11)	Backlash	= 0.6 | P

There are what is called short-tooth gears, and it is claimed by the advocates of short teeth that the strength of the gears so devised will average some 25 per cent higher than that due to the form as above outlined. The short-tooth form, as devised by C. W. Hunt, is probably the best known. Cutters have to be special, and it is a question if the game is worth the candle. On the other hand, the "stub-tooth" gear is now used, in which the base section of the tooth is greater, and the manner of cutting takes into account the principle of the gear shaper rather than the use of fixed cutters. Of course, the angle changes, in the stub tooth, as compared with the regular involute.

Speaking again of the face of teeth, considering the pitch, it is to point out that the rigidity of the spindle is something to take into account and in this connection it is plain that the rigidity depends upon the length to a vast extent, and the length in turn will be far longer for the progressive form than for the selective type of gear. If the spindle is not rigid, it is then plain that the face of the teeth of the gears will contact at a point only, and the face is of no value unless to afford strength of the tooth to resist bending. As against bending, the best guarantee

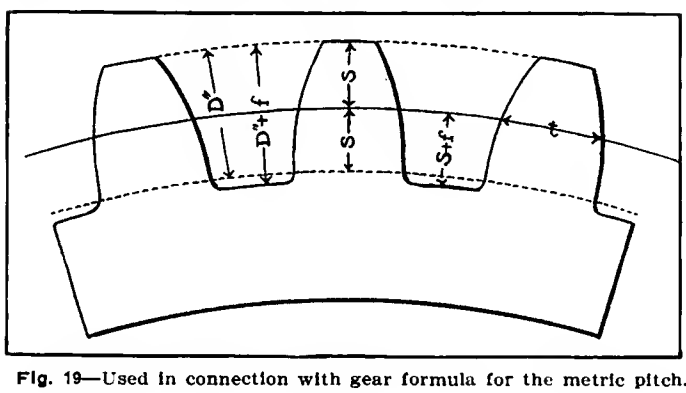

Fig. 19—Used in connection with gear formula for the metric pitch.

is good material, and with a view to defeating other ills, it is best to keep the weight and the diameter low—very low indeed.

For a pair of gear wheels the general formula is usually given as follows, and it will be repeated here as a matter of completeness:

Formula for a Pair of Gear Wheels.

(12) $b = 2aP$;

(13) $N = \frac{nv}{V}$;

(14) $n = \frac{NV}{v}$;

(15) $N = \frac{bv}{v + V}$;

(16) $n = \frac{bV}{v + V}$;

(17) $n = \frac{P D' V}{v}$;

(18) $v = \frac{P D' V}{n}$;

(19) $v = \frac{N V}{n}$;

(20) $V = \frac{nv}{N}$;

(21) $D' = \frac{2aV}{v + V}$;

(22) $D = \frac{2a (N + 2)}{b}$;

(23) $d = \frac{2a (n + 2)}{b}$;

(24) $a = \frac{b}{2P}$;

(25) $a = \frac{D + d'}{2}$;

(26) $d' = \frac{2aV}{v + V}$;

In which,

P = diametral pitch (the number of teeth per inch of the pitch-diameter).

D′ = pitch diameter in inches (of the large wheel).

D = whole diameter in inches (of the large wheel).

N = number of teeth (on the large wheel).

V = velocity (of the large wheel).

d′ = pitch diameter in inches (of the small wheel).

d = whole diameter in inches (of the small wheel).

n = number of teeth (on the small wheel).

v = velocity (of the small wheel).

a = center distance in inches of the two wheels.

b = sum of the teeth in the two wheels.

t = thickness of tooth in inches on the pitch circle.

s = subdenda.

D″ = working depth of tooth in inches.

f = bottom clearance of tooth (allows for radius) in inches.

D″ + f = whole depth of tooth in inches.

P′ = circular pitch = center to center distance of teeth, measured on the pitch circle, in inches.

Formulæ Used in Metric Pitch Gear Designing.—In many of the cars, notably of the foreign design, gears are designed along lines, taking into account the "metric pitch," in which the "module" is equal to the dimension marked "S" (see Fig. 19), which is the distance from the pitch line to the bottom line of the tooth. In foreign gear work, the further difference is by way of "stub-teeth" in many cases, which to be sure, is a modification of the "involute." The module is given in millimeters, and it follows that all the other dimensions should be in the same units. In many of the foreign cars, as they come to America, the practice (considering the gears in the transmission) is to use gears of a pitch equal to the 4 module. This pitch is equal to 6.35 diametral pitch in the English system.

In general in this work, the module is equal to the pitch diameter in millimeters, divided by the number of teeth in the gear. In the same way it is possible to say that the pitch diame-

ter of a gear in millimeters equals the module multiplied by the number of teeth, and in a comprehensive way, the general formulæ of the metric gear system can be set down as follows:

Let,

M = module in millimeters;
D′ = pitch diameter in millimeters, of the gear;
D = whole diameter, in millimeters, of the gear;
N = number of teeth in the gear;
D″ = working depth in millimeters, of the teeth of the gear;
t = thickness in millimeters, of teeth on the pitch line;
f = bottom clearance, in millimeters, of the teeth of the gear;

then,

(27) $M = \frac{D'}{N} = \frac{D}{N+2}$;
(28) $D' = NM$
(29) $D = (N+2)\,M$
(30) $N = \frac{D'}{M} = \frac{D}{M} - 2$;
(31) $D'' = 2\,M$
(32) $t = M\ 1.5708$;
(33) $f = \frac{M\ 1.5708}{10} = 0.157\ M.$

The question of relative advantages of gears cut in accord with the metric system as compared with the best American practice is an idea depending upon whether or not the whole car is designed in one way or the other. If all the rest of a car is in compliance with the metric system, it is then good practice to use the same system for the gears. The involute form of cutter for metric work is now to be had in stock from Brown & Sharp Mfg. Co., and such other firms as cater to the class of trade using the metric system.

Bevel and Miter Gear Work.—It is now considered that well-cut bevel or miter gears are not only strong, but they are noiseless performers as well. In the early days of the automobile the several questions in relation to this class of gears were not given the attention they deserved and the results were below a fitting standard. As the result of more exacting requirements, gear shapers were brought out, and the end is that "fixed cutters" are now little used for the purpose if it is desired to afford noiseless performance.

It is well understood that bevel gears produced with fixed cutters are not theoretically correct; they cannot be, for the reason that the curve in the teeth, when they are properly formed, changes constantly, from one end of the tooth to the other. Fixed cutters cannot, of course, conform to the changing requirement, and as a result, gears produced by fixed cutters are not accurate, and the difference is enough to produce noice, which is the phenomenon to be avoided.

The Angle of Pressure or Obliquity Must Be Considered.—In bevel gear work in particular it seems to be a fact that the old standard angle of obliquity makes for noise. In this connection, it may be well to say that in spur gears the same question is sometimes given attention. The old angle (as originally brought out by Professor Willis, some fifty years ago) was 14 1-2 degrees, while in the most modern work the angle of obliquity is over 20 degrees, and in some cases of good results, this angle was fixed at 22 1-2 degrees.

It is true, to be sure, that the spindles (shafts) should be more rigid on the ground that, with the higher angle, the gears crowd more than if the angle is 14 1-2 degrees. This is but a detail which can well be cared for in the design, whereas, noise due to the angle of obliquity cannot be cared for at all. With the fine materials to be had at the present time there is no use in having the face of the gears so very wide; the wider the face, the greater the chance of having trouble from the point of view of noise.

In any event, it is not well to have pinions with a small number of teeth, and this is even more to be considered in connection with bevel gears than will be the case if the gears are square cut. There is no good reason for having less than 18 teeth in the pinion of bevel drives, and it is an advantage by way of a reduction of noise to maintain the statue of the bevel drive as follows:

(a) Keep the pitch-line velocity below 1,000 feet per minute;
(b) Use pinions with more than 14 teeth;
(c) Adopt an angle of obliquity of more than 20 degrees;
(d) Design with a view to symmetry of section;
(e) Fashion the teeth to the theoretical shape;
(f) Mesh the gears to run on the pitch line;
(g) Support the thrust so rigidly that the gears will not spread away from each other; if they do, it is equal to setting them off of the pitch line;
(h) profuse lubrication is essential to noiseless performance;
(i) use thrust bearings which can be adjusted while the gears are in motion; it will then be possible to adjust the meshing members by sound; absence of noise will indicate that the gears are rolling on the pitch-line;
(j) make the case strong enough to take the thrust; have the walls thick enough to vibrate at a low rate; the sound will be less noticeable;

Formulæ Used in the Designing of Bevel and Miter Gears.

There are divers ways of approaching the matter in hand, and it is more a question of getting used to some one way than than it is of the virtue of any one scheme. At all events, if the designer does not furnish all the means by which the machinist can proceed it is assured that the work will not come out in first-class shape, on the count that what the designers cannot reduce to practice the machinist cannot guess at, and deliver all the cardinal virtues with success. The formulæ, as follows, will scarcely require further explanation; they are used in the haunts of designers; they are of no value outside:

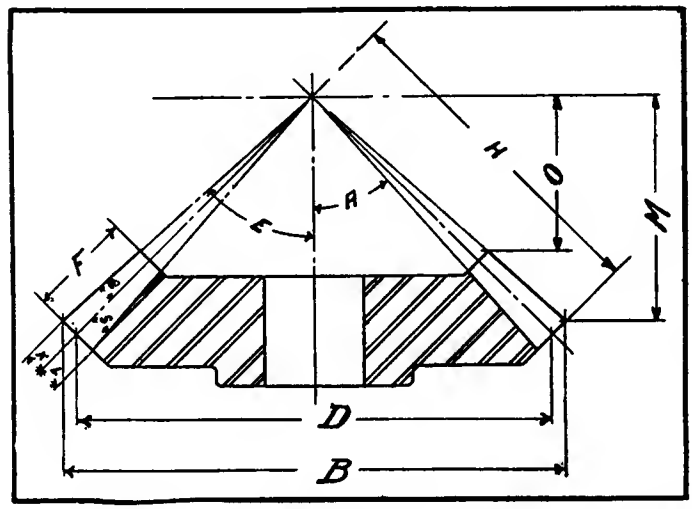

Fig. 20—Diagram of a miter gear for use in connection with formula of the same.

Formulæ for Miter Gears.

P = Circular Pitch; N = No. of Teeth.

(34) $D = \frac{N\,P}{\pi} = .3183\ N\ P$;
(35) $B = D + (.6366\ P\ SIN.\ 45°) = D + .4497\ P$;
(36) $A = 45° - S$;
(37) $TANG\ S = \frac{L}{H} = \frac{.368\ P}{D \times .7071} = .5204\ \frac{P}{D}$;
(38) $E = 45° + C$;
(39) $TANG\ C = \frac{K}{H} = \frac{.3183\ P}{D \times .7071} = .4501\ \frac{P}{D}$;
(40) $M = \frac{D}{2} - (SIN.\ 45° \times .3183\ P) = \frac{D}{2} - .2250\ P$;
(41) $O = M - (F\ COS\ E)$;
(42) $H = D \times .7071$;
(43) $L = .368\ P$;
(44) $K = .3183\ P$.

NOTE.—The letters used in the formulæ for the miter gears are explained in Fig. 20. All dimensions are in inches, and in view of the clearness of the figure it will not be advantageous to complicate the situation further.

Miter gears are not much used in automobile work on the count that in the bevel drive it is generally the case that the ratio is not unity. It is true, however, that in some makes of motors the miter gear design has a resting place, and in such cases it is the custom to use a good grade of carbon steel, as a rule, the same to be quite low in carbon, of the acid open-hearth genera. and case-hardened. In other cases, with a view to noiselessness, it is the practice to use alloy steel in the normal state in order to avoid the deformation which is so prone to follow heat-treatment of any sort. This is especially the case when the parts to be treated are in the shape of bevel gears. The reason for using alloy steel in the cases in which heat-treating is avoided is with the view of securing hardness and strength sufficient for the needs. In a few cases which came under the observation of the author the nature of the work was not well considered, and the untreated miter gears of soft carbon steel failed to take kindly to

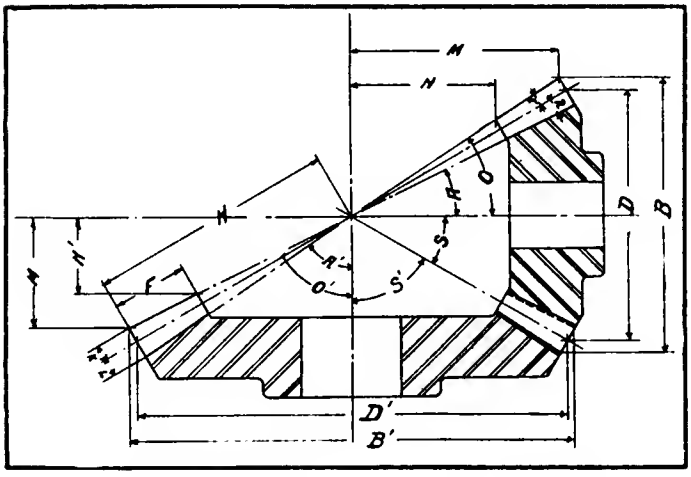

Fig. 21—Diagrammatic Layout of Bevel Gear Set.

the rather peculiar service. It will be remembered that the torque is far from constant; the cam pressure is of an intermittent nature, and that the maximum pressure is a little high and must be allowed for if the life of the gears is long.

Formulæ for Bevel Gears.

Y = No. of Teeth in Pinion; Y′ = No. of Teeth in Gear; P = Circular Pitch.

(45) $D = \frac{Y\,P}{\pi} = .3183\ Y\ P$;

(46) $\text{TANG } S = \frac{Y}{Y'} = \frac{D}{D'}$;

(47) $B = D + (.6366\ P \text{ COS } S)$;

(48) $\text{TANG } E = \frac{.3183\ P}{H} = \frac{K}{H} = \frac{2 \text{ COS } S'}{Y}$;

(49) $\text{TANG } R = \frac{.368\ P}{H} = \frac{L}{H} = \frac{2.3122 \text{ COS } S'}{Y}$;

(50) $O = S + E$;

(51) $A = S - R$;

(52) $M = \frac{D'}{2} - (.3183\ P. \text{ SIN. } S)$;

(53) $N = M - F \text{ COS } O$;

(54) $D' = \frac{Y'\,P}{\pi} = .3183\ Y'\ P$;

(55) $S' = 90° - S$;

(56) $B' = D' + (.6366\ P \text{ COS } S')$;

(57) $N' = M' - F \text{ COS } O'$;

(58) $M' = \frac{D'}{2} - (.3183\ P \text{ SIN. } S')$;

(59) $H = \frac{D}{2 \text{ COS } S'}$;

(60) $K = .3183\ P$;

(61) $L = .368\ P$;

(62) $O' = S' + E$;

(63) $A' = S' - R$.

NOTE.—The letters used in the formulæ of the bevel gears will be found in Fig. 21, there afforded for the purpose of rendering the formulæ as clear as possible; the dimensions are all in inches.

Characteristic Bevel Gear Work.—The diagrammatic cut, Fig. 21, in conjunction with the formulæ of the bevel gear set, will serve in the ordinary course of events, provided the details under which the gears have to serve are taken into account. In this class of work as it relates to automobiles it is generally the case that the gears are used in conjunction with sliding gears to make the right-angle drive, and advantage of the opportunity is taken to reduce speed, using the bevel gear set for the purpose. In this service the torque is maximum and the gears have to do all the work required to drive the car; it is also a fact that the "working" brakes (in many cases) transmit through the bevel drive. It follows, therefore, that the bevel drive must be capable of sustaining under severe service and conditions that are not so very good from the point of view of weak parts.

In view of the fact that the bevel drive is in cramped space, it is difficult to afford long distances between the sustaining bearings, and unless the work is well done it is assured that the gear-set will be pinched in the process, and it is noise which will follow. True, bevel gears can be rendered quite noiseless if they are well cut and provided they are set to run on the pitch-line, assuming that the housing is so strong as not to deform under pressure, allowing that the bearings are capable of doing all the work, part of which is as a thrust.

This question of the thrust load is difficult to handle, in view of the extent of the same, and in further view of the fact that the distance between the bearings is short, as before stated. Then it is true that but slight displacement will be enough to allow noise to creep in, and it is this noise which is to be aborted at any cost. The time has passed when autoists will be satisfied with cars merely because they will run; they must perform in a noiseless manner as well. To assure noiseless performance the bevel drive must be devised, taking into account the fact that the thrust does introduce disconcerting details, under the circumstances.

Materials Used in Bevel Gears.—While it is true that bevel gears do not "clash" and do not have to withstand the resultant shock load, the fact remains that the materials to use should be of a character such as will sustain under very severe conditions. Case-hardened steel is much used in this class of work, and if it is of a good grade it will do the work in a manner to leave little to be desired. On the other hand, in gears such as are subject to a double process in heat-treatment, warping becomes the more pronounced, and on this account some designers prefer to use alloy steel in which the carbon content is so related to the alloys as to bring about hardness as a result of quenching without having to resort to the cementing process.

As an illustration of materials such as would serve for this class of work and be hard enough for the purpose in the absence of a cementing process, reference may be had to the following:

Carbon.	Chromium.	Nickel.	Manganese.	Silicon.	Sulphur.	Phosphorus.
.35	.66	3.50	.40	.20	0.28	0.25

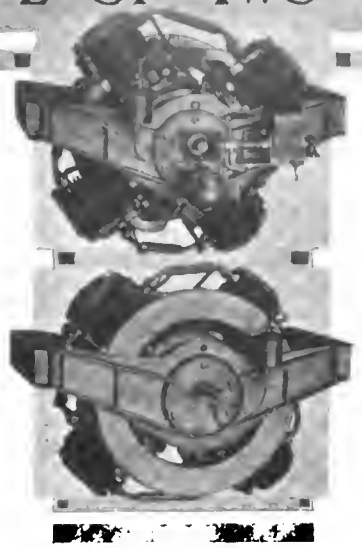
It is also possible to use steel somewhat as above, with nickel as low as 2 per cent., increasing manganese somewhat.

It is also practicable to take into account the use of nickel steel in which the carbon should be very low if the steel is to be cemented. Some makers prefer to employ this same grade of steel high in carbon, and hardness is attained through the quenching process in the absence of cementing, while an attempt is made to impart dynamic ability in the subsequent annealing process.

If vanadium is taken into account it is the idea to limit the percentage of the same in the composition to less than .15 per cent., on the ground that the performance of materials in which this element enters is far from good when the element assumes greater proportions. This is especially so in parts to be cemented, and it is enough of a factor to be taken into account, no matter what the heat-treatment may be.

If any alloy steel is used it must be considered that such products are difficult to machine and more difficult to handle in the gear-shaper. On this account many makers prefer to rely on the use of "cementing" carbon steel, in which, as before stated, the carbon content should be held below 16 points.

REVOLVING TYPE OF TWO-CYCLE MOTOR



INSTEAD of using a fan to force air over heated surfaces of the cylinders of a motor, one idea is to force the hot surfaces of the motor through the air, and in this way produce the maximum cooling effect in the absence of any special device for the purpose, as a fan. When a car is making about 20 miles per hour it is quite well understood that the amount of air displaced by the car in its transit is that which will cool the motor. This has small bearing upon the case unless to make the point that the motor as shown is so designed that the heated surfaces of the cylinders cut through the air at the rate of about one mile per minute; the amount of air which sweeps by the cylinders is therefore more than the amount which is looked upon as necessary for the purpose, if it can be assured that the air is allowed to brush the heat off of the interior surfaces of the cylinders, as it should be able to do.

In view of this expectation it is the idea in this case to not only do away with water, but to resort to the two-stroke-cycle principle as well. It is well understood that in the motor of this type there is the advantage of double the number of power strokes, and if any means can be devised so that the impulses can be given the same vigor as in the four-cycle motor, double the power will follow, considering a given cylinder diameter and a given stroke. To accomplish all these things is something of a job, but it is the task of N. O. Allyn, of Hiram, O., who has worked along these lines until now he has something to show by way of a motor, the performance of which looks so promising that he proposes to see more of it. In this motor the use of a flywheel is not necessary, since the moving mass is adequate for the purpose for which a flywheel is generally used in conventional work.

The illustrations here afforded will show at a glance the exterior details of the motor, and, as will be noted, the power is that due to the use of four cylinders, each of which has a bore of 4½ in., with a 4-in. stroke. The motor, according to the designer, makes 900 revolutions per minute, and at that speed develops 33 hp. It is claimed that in repeated tests in duration equal to three hours in each case, the cooling was effective and the power maintained with indications of excellent stability.

The ignition is by means of a high-tension magneto in the absence of a battery and coil; the manner of gearing the magneto is shown to be a bevel drive located at the side of the frame, and in a position to be examined at will. The carbureter is also located on the frame in a position near the magneto, and on the whole, despite the fact that the cylinders rotate, the parts are accessible.

The frame is somewhat heavy, as would be expected, in view of the load, and that this is a detail which the inventor proposes to treat with is assured. The piping between the cylinders is nicely done; account is taken of the centrifugal force, and the kinetic balance of the rotating mass is well cared for, which means that all the parts are machined to size. Symmetry is aimed at, and care has been exercised in the assembling of the parts.

Locally, this motor has been the cause of considerable interest, and that local capital will be interested is assured, rather with the hope, perhaps, that in time the plan will prove to be as good as it looks, taking into account the splendid performance reported, despite the disappointments which always attend a first model.

MORGAN TRUCK HAS ORIGINAL FEATURES.

WORCESTER, MASS., Feb. 22.—The new truck recently produced by Ralph L. Morgan, of this city, bids fair to take a high rank in the automobile world. This is the result of several years' labor on the part of Mr. Morgan, and possesses many original features. The biggest claims made for it are in the line of simplicity, in which respect it is said to be a model for others to copy, all superfluous, unnecessary or complicated parts having been eliminated.

Rated at five tons nominal load the parts are proportioned for a 40 per cent. overload despite which fact the weight of the car light is kept down to 7000 pounds. The features of the truck which differ from the normal car are the differential lock, pressed-steel wheels, extra high clearance, unusually large and powerful brakes, 24-inch steering wheel, chrome nickel-steel gears in the all-spur gear planetary transmission.

The motor is of the four-cylinder, four-cycle vertical type, of 5-inch bore and 5-inch stroke. To decrease the length of the whole vehicle, the wheelbase and consequently the effective turning radius, the driver has been placed over the engine. The first trucks produced have seen hard service in and about Worcester in the past year, one of them hauling 333,000 pounds of steel and wire in a five days' test. Another hard tryout was the hauling of four tons a distance of 146 miles in thirteen hours. Normally geared to twelve miles per hour on the low speed under full load, the car has been able, so it is said, to climb a 16-per cent. grade with ease, and to perform under severe conditions quite in keeping with exacting commercial requirements.

MOTOR-DRIVEN VS. HORSE-DRAWN TRAFFIC.

NORRISTOWN, PA., Feb. 22.—Two parallel roads, built of the same material, one for the use of horse-drawn vehicles and the other for automobiles, to study the general effect of the two classes upon the surface, a plan that has often been advocated but rarely, if ever, tried, will probably be the result of the speech made by former Assemblyman John H. Rex last Thursday evening before the road supervisors of Montgomery County.

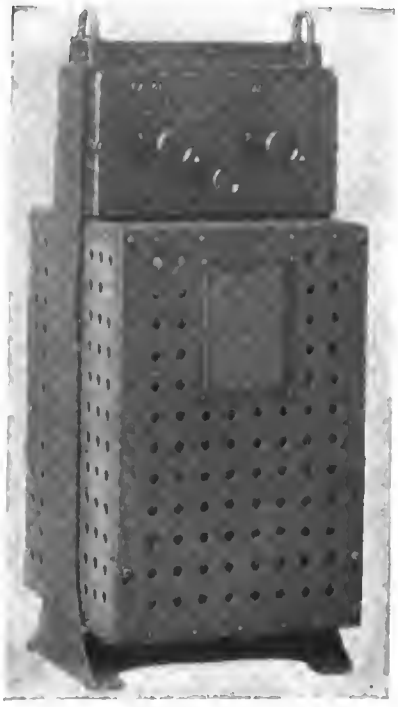
Mr. Rex had been invited to speak upon the subject of taxing automobiles to maintain the improved highways, and his talk was novel and interesting, and he advocated some measures that were recognized as fair to all. Among them would be a tax upon both autoists and horse drivers, according to the damage done by each as shown by the proposed test; another would be a different set of taxes for cars with a wide touring radius as distinguished from those doing duty in any one place.

BRITISH DISCOVER NEW TOOL STEEL.

Alloy steel is of such great importance to the automobile maker that the most recent discovery now being heralded in the papers is entitled to "space." In automobile work "tungsten steel" has been relied upon as the mainstay for fashioning parts of alloy steel, and the present claim is to the effect that the new tool steel is superior to anything ever before known for the purpose. Prof. Arnold of the Sheffield University, England, in his discussion of the discovery lends stability to the claims. The exact nature of the new steel is not disclosed.

MERCURY RECTIFIERS FOR CHARGING BATTERIES

GENERALLY speaking, to charge an ignition battery is to waste much of the energy in the process because the charging circuit, if it is that of the regular service from the street, will be of a far higher electromotive force than the counter electromotive force of the battery, with the result that a dead resistance has to be inserted in order to regulate the charge, for the battery would be destroyed in the absence of some suitable device. That is, assuming a direct current is used. With an alternating current it would not be feasible to charge a battery at all, for the reason that the charging would be as the algebraic sum of two forces in a zero equation. This is true in the absence of some device which is capable of rectifying the alternating current, which device should at the same time render the current acceptable in point of electromotive force.



Type A Mercury Rectifier for Charging Vehicle Batteries.

In many places, however, the alternating current will be available where the direct current cannot be obtained, for the reason that "static transformers" used in connection with the alternating current make it possible to transmit the current at a high electromotive force, and step-down the voltage when it is desired to use the current for lighting, power or charging purposes. The loss in transmission, considering an electrical circuit, is directly proportional to the length of the circuit and inversely proportional to the sectional area of the conductor (copper wire). Since the direct current cannot be transformed (in the absence of a rotary transformer), the alternating current possesses an enormous advantage.

Mercury Rectifiers Render Alternating Current Potent.—Taking into account the fact that an ignition battery with, say, three cells of secondary batteries in series, has a maximum charging potential difference of 7.8 volts, to which should be added the drop in volts in the system, making the total not more than 10 volts maximum, it is plain to be seen that a rectifier should be so designed as to enable the same to work on a lighting circuit, the voltage of which is generally 115 volts. Besides acting as a step-down transformer, it is necessary to rectify the alternating wave. This is the function of the mercury rectifier, one of which is here illustrated (see Type E Westinghouse ignition battery rectifier), of convenient size, and in which there are no rotating members.

The Type E Westinghouse rectifier is made especially for rectifying alternating currents to be used in sparking battery charging. It is small, since the capacity does not have to be great in view of the size of the battery, and it is mounted on a panel in such a way as to afford all the advantages of a self-contained unit. The Type E unit is in principle the same as the Type A Westinghouse rectifier, which has greater capacity for larger work. In both cases the efficiency is high, which is fortunately an advantage of the mercury method, and the life is long, so that the cost of upkeep is nominal. In the plan there is nothing to take into account from the danger point of view, for the rectifier is provided with all the protecting devices dictated by experience and a high regard for utility in the absence of drawbacks of every character.

Purpose of the Type A Rectifier.—In many cases it is desired to charge batteries for vehicle work, in which the batteries are large in proportion to ignition batteries, and for this purpose the Type A mercury rectifier is adapted. It is of a capacity to handle the largest battery used in vehicle service, which takes into account 44 cells, each of which, on charge, demands 2.6 volts (maximum) for a correct charge. The result is that the rectifier must deliver $44 \times 2.6 = 1144$ volts, not including the loss in the system. On the whole, it requires a system affording an adequate current at about 220 volts electromotive force, and the Type A rectifier is intended to care for this. It also is a self-contained, and on account of its high efficiency is looked upon as a very desirable equipment for the purpose.

There is one more point to be considered—battery, in any given case it must be charged on a basis to maintain the temperature within limits, and means must be provided to prevent overheating it. These rectifiers are almost automatic, and they are devised to enable a novice to do the work. If a battery comes in "hot" the charging current must be limited to suit the lowered counter electromotive force, which is one of the manifestations of the heated condition of the battery. There is the question of a full corrective charge to be considered, and means are provided such as will enable the operator to taper off the charging current at will in full accord with the exacting needs of the occasion.

Increased Range of Utility of Electrics.—Because the mercury rectifier will do the work for which it is devised it is of great importance to the industry, for it affords the advantages of being enabled to utilize the alternating current in charging. Nearly every hamlet in the land is provided with an alternating current lighting plant, and as a result every hamlet may be a center of electric vehicle activity, since the batteries can be readily charged by the use of the alternating current rectifier. In private service there is nothing more in keeping with the needs for comfort and convenience than a garage in the yard of a residence.

Type E Mercury Rectifier for Charging Ignition Batteries.

TEN YEARS' PROGRESS IN MAGNETO IGNITION*

By J. A. WILLIAMS, President of the K-W Ignition Company, Cleveland

IT is an indisputable fact that the gas and gasoline engine of to-day, as far as the engine itself is concerned, is practically perfect, and is not susceptible of further great improvement.

There remain, however, two very important functions of the gasoline engine which, when developed up to a stage as perfect as the engine, will make the internal combustion meter not only the most economical, from a technical and commercial standpoint, but the most reliable source of power extant. These two functions are those of ignition and carburetion. I have chosen for my subject, ignition. Not that it is of greater importance than carburetion, for they are equally important to the successful operation of the engine, but as I have devoted years to the study of ignition, I feel more competent to discuss it.

Hot Tube the First Type of Ignition.—The first type of ignition which achieved any commercial success was the hot-tube type, which has been superseded by electric ignition, either of the make and break or jump-spark type. The former is more commonly used on large and slower-running engines, while the jump-spark type is more applicable to smaller-powered, higher-velocity engines. The reason for this is, that the mechanical circuit-breaking mechanism for make-and-break ignition is extremely difficult to make of sufficiently small size and light weight as to render it positive at very high speeds.

The jump-spark system of ignition is capable of being successfully operated at very high speeds, as the problems in it are more of an electrical, than a mechanical nature. In other words, the difference between the two has been aptly defined as follows: The make-and-break is complicated mechanically, but simple electrically, and the jump-spark, simple mechanically, but complicated electrically. As to virtue, both are good, and as far as I have ever been able to ascertain, equally good, provided that the apparatus and mechanism employed are of a substantial and satisfactory nature. In either system, the two most important factors to be borne in mind are the creation of a spark that is intensely hot and the proper timing of it.

On make-and-break ignition the spark which is created is composed of what is termed, dynamic electricity, the heat value of which is estimated by multiplying the voltage across the terminals of the arc, by the amperes of current flowing through the spark. The product is the heat units expressed in watts. Now, this same law applies to the estimation of the heat units of the jump spark, provided that the jump-spark is composed of dynamic instead of static electricity. A great many sparks that are used in jump-spark work are static instead of dynamic. The static spark makes a snappy sound, but will only indifferently ignite the charge, whereas a jump-spark that is composed of dynamic electricity, has a reddish appearance, does not have a snappy sound and is intensely hot.

Coils Produce Two Kinds of Sparks.—The spark coils that produce either a dynamic or a static jump-spark look alike, but the defects which make a static spark are: First, that its windings are improperly proportioned to each other, and to its condenser capacity; and, second, through dampness in the insulation of the coil, producing a leakage, which forms a partial internal short circuit in the secondary winding, the result of which neutralizes the self-inductance of the primary winding, consequently permitting the condenser discharge to oscillate at enormous frequencies through the primary winding. This sets up a static current of high voltage and frequency in the secondary winding.

A properly designed and constructed spark coil should simply act as a transformer to transform low-voltage dynamic current into high-voltage dynamic current, but where there are faults in the design or construction of the coil, which permit high frequencies to come into play, it delivers from its secondary winding, static instead of dynamic current. In the design and construction of the spark coil, the object should be to keep down the frequency of oscillation to just as low a point as possible, so as to get just as pure a dynamic current out of the secondary as possible. A static spark is composed almost entirely of high frequency, high voltage, with no appreciable amperage or volume, consequently it has not sufficient heat units.

Which Spark Gives Most Power?—There is no doubt that the majority of jump-spark coils in use to-day are not delivering pure dynamic sparks, but largely static sparks. This feature calls to mind the much-discussed question as to which of the two sparks, make-and-break, or jump-spark, give to an engine the more power. Some have said make-and-break, and some, jump-spark. No doubt when a good make-and-break spark is compared with a poor or static jump-spark, the evidence is all in favor of the make-and-break spark, but in reality if a good hot, dynamic current, jump-spark is compared with the same character of current in a make-and-break spark, there will be found no difference in the power developed by the engine with either of the two systems of ignition. The power given to the engine, therefore, does not depend upon what system of electric ignition it has, but entirely upon the current used.

In make-and-break ignition, there is no way to make a static spark, consequently all are dynamic, but in jump-spark ignition, with cheaply constructed coils, the majority of the sparks in use, are static, and consequently very low in heat units.

The timing should be so arranged that the engine will receive the full force of the explosion at its dead-center position or immediately thereafter, as in this position the mixture is at its highest point of compression, and occupies the smallest space. The spark, however, should occur slightly before this, the amount in advance depending, first, upon the character of the mixture, its homogeneity and chemical composition; and, second, upon the heat of the spark. For instance, take a mixture that is either of an improper proportion or that is poorly mixed, and it will require more spark advance than a mixture of proper proportions that is homogeneous and well mixed, or a weak spark will require considerably more advance to light any mixture than will a hot spark.

Hot Spark Creates Complete Combustion.—This is one reason why a hot spark gives more power than a weak spark, and is the principal reason, for the hot spark does not start combustion until the compression stroke is nearly or entirely completed and it propagates through the charge more rapidly, thus creating complete combustion when the gas is compressed in its smallest volume, consequently raising it to a higher temperature, giving a greater thrust to the piston and maintaining its thrust at greater pressure through the entire power stroke.

In multiple cylinder engines, the timing of the spark must be exact. In other words, there must be synchronism or equal time between the occurrence of the spark in the different cylinders. In further explanation, the spark must occur at exactly the same point on the crank-shaft circle for every cylinder. Let us take for example a three-cylinder engine; should the explosion occur at exact dead center, in cylinder 1, 20 degrees before dead center in 2, and 20 degrees after dead center in 3, you would have only one cylinder giving its full quota of power, namely, cylinder 1. Cylinder 2 would spend part of its power trying to reverse the engine while cylinder 3 would fall 20 degrees short of giving a full-power stroke. This example is by no means a common condition, but it seems to be the rule rather than an exception.

With make-and-break ignition on multiple-cylinder engines, it is hard to maintain exact synchronism, owing to the wearing of

* Paper read before the National Gas and Gasoline Engine Trades Association at Chicago, February 9, 1909.

the ignitor points and circuit-breaking mechanism. With jump-spark ignition, where the timer segments are equally spaced, and where a master vibrator is employed to break the circuit for all the coils, no such difficulty is encountered, but exact synchronism is established, and maintained all of the time between all of the cylinders. Where a master vibrator is not employed, it is difficult to adjust the vibrators of the different coils so as to get exact synchronism. It is possible, however, to build coils which will synchronize without a master vibrator. In other words, coils which are auto-synchronous, no matter how their vibrators are adjusted.

The Two Sources of Current.—There are two sources of electric current for ignition. One is the magneto, which generates a current by mechanical means, the other is a battery, which generates current by chemical means. There are three types of magneto ignition. The most recent type is the inductor type of magneto which has no moving wires, commutators or brushes, and which generates a sine wave of alternating current. The second is a dynamo type, has a commutator, brushes and a drum-wound armature, also has a permanent magnetic field. This type is merely a dynamo with permanent magnets instead of electromagnets for its field. The third is an alternating-current magneto which is equipped with its own circuit breaker and distributor, and is commonly called a high-tension magneto. This type is also often made with a circuit breaker, distributor and a primary winding on it, which operates on a coil, external to the magneto. It is a low-tension magneto, but is frequently incorrectly called a high-tension magneto.

In this article we will refer to magneto ignition as used on the make-and-break system of ignition, and on the jump-spark system of ignition where a timer and vibrating spark coil are used. The magneto system is, of course, more expensive in first cost, but if a properly designed magneto is used, there is no appreciable maintenance charge. If batteries are used, while the first cost is lower, the maintenance charge begins with the starting up of the engine and never stops as long as the engine is in use.

Ignitors Last Indefinitely.—On make-and-break ignition there is a very decided reason for using magneto over battery ignition, for with a properly designed magneto, the ignitor points in the cylinder of the engine last indefinitely, and may be made of very cheap material, such as steel, or German silver, for the voltage which the magneto delivers is sufficiently high to overcome any ordinary resistance, such as oxidized or dirty points, whereas the ordinary battery which only delivers from four to six volts for make-and-break ignition, requires clean contact points of a metal which will not oxidize.

The dynamo type of magneto which has a commutator, brushes and governor, and which operates through means of the ordinary kick coil, just as batteries do, is no better in this respect than batteries. The proper type to use for make-and-break ignition is the inductor type, which requires no coil, as the winding on the magneto itself acts as a kick coil, so that when the circuit is broken, the voltage across the ignitor points will range very close to seven hundred volts, according to winding of the magneto and its speed, although the amperage will be small.

Voltage Very Low with Batteries.—With battery or ordinary dynamo-type magneto, the first voltage, that is, the one used in charging the primary or kick coil, is necessarily extremely low, from four to six volts, and the voltage across the points when they break is about sixty volts. Now, assuming that both sparks have the same amount of energy, the one from battery or dynamo type of magneto would have ten times the current and ten times the destructive effect upon the ignitor points of the engine than would the inductor type of magneto. It is not voltage that burns out points, but it is the amperage.

The inductor-type magnetos that I am most familiar with have a primary voltage of about 70 volts, which is ample to go through any set of ignitor points, no matter how burned, pitted or oxidized they may be, and as this is multiplied about ten times by the breaking apart of the ignitor points, there is about 700 volts with a consequently small amount of amperage thrown across the ignitor points as they separate. An additional advantage of the inductor type of magneto over the dynamo type for make-an-break ignition is, that the former can be positively gear driven at crank-shaft speed for engines of one, two and four cylinders, and at one and one-half times crank-shaft speed, for engines of three and six cylinders. The inductor type has the further advantage of passing current through the ignitor points in a very much smaller interval of time than a battery or dynamo type can charge a primary coil, therefore the circuit-breaking mechanism on the engine can be so constructed as to close the circuit for a very small interval of time, thereby taking up a lot of the lag in the circuit-breaking mechanism.

Now, when using a primary or kick coil with battery or dynamo-type magneto, it takes such a long time for the primary coil to become charged with current that the circuit-breaking mechanism on the engine has to keep the contact points together for a considerable period of time in order to charge the coil, and then when the tripping mechanism operates, the circuit breaker has to swing through a long arc of its travel before it breaks the contacts apart, thus causing a considerable lag in the circuit breaker. The inductor-type magneto permits of the use of a circuit breaker for make-and-break spark which will operate the engine at engine speeds fully as high as any jump-spark system could operate under.

Coil Is the Most Important Factor.—In jump-spark ignition the most important factor in the apparatus is the spark coil, which looks very simple, but there is enough electrical science employed in the construction of one to fill volumes in describing it. All that we can say about it here is that it must be so designed and built as to produce a dynamic instead of a static spark. It must have a very quick time constant, permitting it to operate on timers of very short segments, thus economizing battery current. Furthermore, is should have a vibrator constructed with reference to the time constant of the coil and so constructed that a careless user could not possibly adjust the vibrators so as to make the coil take more current than its insulation would withstand.

Soft platinum points should not be used, but an alloy of such a percentage of iridium and platinum as will permit a very hard and dense point and one which will not weld itself together as soon as it heats up. It must be borne in mind that pure platinum is a very soft, and spongy metal, and will weld together at extremely low temperatures, while iridio-platinum contact points require a very much higher temperature before they will weld. In the construction of spark coils the very best of insulating materials should be employed, and after the windings are made, they should be pumped out in a hot vacuum, thus exhausting all of the air and moisture. They should then be impregnated while under vacuum with a dielectric of heat-and-moisture-resisting qualities, thus preventing all electrical discharges and leakage between its turns and layers.

This method of treating coils is quite recent, and is by no means as yet universal among the various coil builders. If spark coils were all built properly with the proper kind of windings, the proper kind of vibrators used, and the coils used in connection with the proper kind of timers, that is, timers which do not have an unnecessarily long period of contact, it would be found that the battery consumption could be reduced very materially.

Inductor Magneto Gives a Hotter Spark.—As to source of current for jump-spark ignition; two kinds of magnetos may be employed, or battery ignition. The inductor-type alternating-current magneto, the voltage of which increases directly as the engine speed increases, gives a much hotter spark at normal rates of engine speed than either the dynamo type of magneto with governor, and which has a fixed voltage owing to its having a fixed speed controlled by governor, or a battery which we know has a fixed and non-increasable voltage.

The reason that increased voltage is required as the engine increases in speed is because the timer contact points in passing over each other rapidly do not come into as intimate electrical contact with each other as when the engine is running slow.

LETTERS INTERESTING AND INSTRUCTIVE

TIME RATE OF EXPLOSION OF ACETYLENE.

Editor THE AUTOMOBILE:

[1,763.]—Since acetylene is an explosive of more than ordinary ability the question is, why is it not adopted for use in automobile work in view of the fact that gasoline is becoming more costly, as time, and it is possible that more power would follow the use of acetylene, considering a given cylinder displacement?

Deep River, Conn. PAMPER.

Acetylene would prove the more expensive of the two. Enough "carbide" is not available to do the work. Mechanically, there is the question of the time in which the acteylene will explode, relative to the time required for gasoline. It is generally considered that acetylene is five times faster than gasoline, and the question is, would not this fact lead to mechanical complications? Acetylene is regarded as suitable for use in fuel mixtures in which gasoline will play a part, and in time, as the fuel problem becomes more acute, acetylene is bound to be utilized, to some extent, at any rate.

If acetylene is capable of exploding five times faster than gasoline it would look as if the question of timing would have to receive more than a little attention, and the compression would have to be very closely regulated. On the whole, it may be that acetylene has not been fairly dealt with in that it has been experimented with but little, probably under conditions which might satisfy the characteristics of gasoline, rather than acetylene. That an increase in power would follow the use of acetylene is probably true, assuming that the mechanical device could be perfected in such a way as to assure results in conformity with the energy in the acteylene; the mixture would be about 3.28 times more powerful than mixtures of gasoline and air.

WET MULTIPLE DISC CLUTCHES.

Editor THE AUTOMOBILE:

[1,764.]—I have a car in which the discs are not lubricated and while the clutch works (when it is in good order) the point is that it does not last long enough to suit me; it could be made to hold oil, with but little work, and the question of the lubricant to use is uppermost in my mind; what is the best practice?

Chicago, Ill. DRY DISC CLUTCH.

The coefficient of friction will be lowered, and if the clutch, with the same number of discs and the same pressure, is rendered "wet," it may not then possess the requisite negative torque. The clutch oil can be half and half light lubrication oil and kerosene oil. If the surfaces are small and the heat generated is enough to run up the temperature to the "flash point" of the oil, it is then that a fire will have to be quenched. If the space is adequate, it is possible to maintain the coefficient of friction, despite the use of oil, by taking advantage of the qualities which reside in "cork inserts." If the clutch will hold, then the heat will not run up to a point such as will approach the flash-point of the oil and the question of a fire will not have to be taken into account.

WHAT IS THE FASTEST MOTORCYCLE TIME?

Editor THE AUTOMOBILE:

[1,765.]—Kindly tell me in "Letters Interesting and Instructive" if a motorcycle ever attained a speed of 135 miles per hour.

Washington, D. C. H. T. CHITTENDEN.

The fastest time recorded as having been made upon a motorcycle is that of a mile in 44 2/5 seconds, a speed of 81.08 miles per hour, made by William Wray on a Peugeot on the Florida beach. This, however, is not recognized by the Federation of American Motorcyclists as a record, because Wray was using a machine with more than 61 cubic inches cylinder displacement, rated at 14 horsepower. The recognized record for the straightaway is 46 2/5 seconds, a speed of 77.58 miles per hour, made by G. H. Curtiss on a Curtiss. The circular track record is 54 seconds, a speed of 66.66 miles per hour, held by Fred Huyck, using an Indian.

SEVERAL THERMOMETER SCALES COMPARED.

Editor THE AUTOMOBILE:

[1,766.]—I do not understand the relation between the several thermometer scales in use and I will be glad to have you enlighten me on the subject; it is possible that others are in the same fix.

Portland, Me. ICE COLD.

Equivalents of temperature scales are quite easy to reduce if the matter is given but a moment's thought. There are three scales in common use: (a) Celsius, (b) Reaumur, (c) Fahrenheit; they relate to each other as follows:

The melting point of ice equals:

Celsius degrees.	Reaumur degrees	Fahrenheit degrees
0	0	32

The boiling point of water equals:

Celsius degrees.	Reaumur degrees	Fahrenheit degrees
100	80	212

(a) To change from Fahrenheit to Celsius:

$$\text{Celsius degrees} = \frac{(\text{Fahrenheit} - 32)\ 5}{9}$$

(b) To change from Celsius to Fahrenheit degrees:

$$\text{Fahrenheit degrees} = \frac{(\text{Celsius degrees} \times 9)}{5} + 32$$

(c) To change from Fahrenheit to Reaumur degrees:

$$\text{Reaumur degrees} = \frac{(\text{Fahrenheit degrees} - 32) \times 4}{9}$$

(d) To change from Reaumur to Fahrenheit degrees:

$$\text{Fahrenheit degrees} = \frac{(\text{Reaumur degrees} \times 9)}{4} + 32$$

The scale Celsius is sometimes called "centigrade"; it is much used in scientific work and it has the advantage of dividing the scale into 100 equal parts, with magnitudes quite up to the requirements as respects utility.

A DIVERGENCE FROM SCOPE OF SUBJECT.

Editor THE AUTOMOBILE:

[1,767.]—I wish to take exception to a statement you make in the February 11 issue of "The Automobile," since I believe the statement to be partial or due to insufficient knowledge on your part of the subject of ball bearings. You say: "If the balls cannot come into contact with each other it is true that noise will be aborted, and since there is no occasion for having a full complement of balls it is the practice to turn out 'silent' ball bearings with separators to aid in the process."

It is possible in but few cases to completely fill the space between two concentric rings with balls so that usually there is left a space not occupied by balls. The result is that in a ball bearing running dry every time a ball is carried over in the direction in which it is moving it bumps the ball in front of it, producing a slight click: if the speed of the rotating shaft is sufficiently great, these clicks follow one another with sufficient rapidity to produce a continuous sound or hum. However, ball bearings are usually lubricated with a light or medium grease, the viscocity of which is great enough to prevent the balls from dropping over. In this case the sound is no longer heard and it is a misstatement of facts to say that the full bearing is not as silent as the cage bearing. In fact, the full type bearing under these conditions is the more silent, as will be shown.

In a full bearing the balls do not press against one another, except sometimes with their own weight, but this is negligible. Between every two balls there is a point contact, and, since the pressure is practically zero, the friction between the balls is negligible and the sound due to the rubbing of the balls against one another is inappreciable. With a cage bearing, there is likewise little if any pressure between the balls and the cages, but the balls now have a surface contact instead of a point contact and the sound due to the rubbing of the balls against the walls of the cages, although very slight, is greater than with a full bearing. It should be remarked, however, that in either case the sound is so

slight that no reasonable objection could be held against either type of bearing as a noise producer.

Are not all cup and cone bearings of the full type? No complaint, so far as I know, has ever been made that these bearings are noisy. Further, it may be of interest to many automobile manufacturers in this country to know that most French cars are equipped with full bearings. Has complaint been made that these bearings are noisy?

The statement that there is no occasion for a full complement of balls, as well as the statement that full bearings are noisy has been used to cover a multitude of desires on the part of ball bearing manufacturers to make a full bearing without any filling slots. And the inability of these manufacturers to do this has been used as a pretext for stating that a full complement of balls is not required. Why not? Will a bearing with four balls in it carry as much load as one with twenty balls of the same size? Let us take for example two bearings having similar grooves or races and balls of the same diameter and made of the same material. The carrying capacities of these bearings will be directly proportional to the number of balls in each race. As a concrete case, if a cage bearing has six balls and a carrying capacity of 1,000 pounds, a full bearing of the same dimensions having, say, twelve balls, will carry 2,000 pounds. Doesn't this mean a better distribution of the load and consequent longer life of the bearing? Why, then, is there no occasion for a full complement of balls?

One can readily understand that a full bearing without a filling slot has certain advantages which cannot be claimed for a full bearing that has such a slot. A radial bearing should not, under any circumstances, whether made with or without a filling slot, be used to carry a thrust load. This applies particularly to bearings carrying great loads at comparatively low speeds. However, designers persist in using radial bearings to carry thrust loads, and it remains to ameliorate conditions until, by education, these designers are convinced that excessive thrust loads should be carried by thrust bearings. When a radial bearing having a filling slot is subjected to end thrust, the balls are pinched at the slot resulting in rapid wear to both balls and races. In a bearing without a filling slot pinching of the balls cannot occur.

When a radial bearing is subjected to a radial load only a few of the balls carry the load, but when such a bearing is subjected to thrust load, this load is carried by all the balls, and the greater the number of balls the greater is the thrust-carrying capacity of the bearing; in other words, other conditions being the same, the greater the number of balls the better the bearing. Then, why do you say there is no occasion for a full complement of balls?

New York City. ASHER GOLDEN.

There is no occasion for having a full complement of balls, if the bearings without a full complement are properly selected. There is no law against having a full complement; they are to be had in the open market. Nowhere in the letter you referred to is the full type discussed at all.

There is small occasion for discussing what will happen in the absence of lubrication. All makers of bearings recommend the use of lubricating oil.

As respects the "foreign practice," no doubt the American makers will greatly appreciate the information you so kindly offer.

You say, "if a cage bearing has six balls and a carrying capacity of 1,000 pounds, a full bearing of the same dimensions having, say, twelve balls, will carry 2,000 pounds." You show utter lack of knowledge of the subject in thus attempting to maintain that a ball bearing increases in ability in direct proportion to the number of balls used.

What you say about thrust loads on radial types of bearings is so foreign to the practices of the day, and of the years back, that force is conspicuous for its absence. If you are right, many builders of automobiles should be willing to pay you a large sum to act for them as nurse.

Don't know why you go to so much trouble to tell how "annular" ball bearings should be built to fit them to work under thrust loads, if they are not to be used for the purpose.

You say that with cages the balls have a surface contact and that sound will follow as a result of rubbing of the balls against the walls. When next you take up the subject, kindly tell us what the oil is for—if the pressure is slight; if the surfaces are oiled, how will the balls squeeze the oil out from between the surfaces?

It is quite useless to discuss the question of what ball bearings to use in slow speed work, in view of the fact that in automobiles the speed is high.

USE A SLIDING GEAR FOR A HEAVY AUTO.

Editor THE AUTOMOBILE:

[1,768.]—I am about to assemble a four-passenger roadster which will have a four-cylinder motor rated at 28-30-horsepower. The car will weigh, when complete, without passengers, 1,800 pounds; will it be practicable to use a planetary gear? If not, why not?

Atlantic Highlands, N. J. SUBSCRIBER.

The car you outline is well within the class called "touring," and should have a sliding-gear transmission with three forward speeds. The reason for this lies in the fact that the motor does not possess the ability to deliver torque on a fitting basis at low speed, and it is torque which must take the place of speed. With a three-speed transmission set it will be possible to run the motor at a speed fast enough to realize power to an adequate extent, and the gear ratio can be adjusted to a point such as will enable you to enjoy that wide range of flexibility so desirable on bad roads in particular.

THE AUTOMOBILE CALENDAR.

AMERICAN.

Mar. 1-6.....Buffalo, Convention Hall, Annual Show, Automobile Club of Buffalo. D. H. Lewis, Secretary.

Mar. 6-13.....Boston, Mechanics Building, Seventh Annual Automobile Show, Boston Automobile Dealers' Association. C. I. Campbell, Manager, 5 Park Square.

Mar. 8-13.....Kansas City, Kansas City Automobile Dealers' Association Show.

Mar. 8-14.....Portland, Ore., First Annual Automobile and Sportsman's Show, Portlsnd Automobile Club. W. F. Lipman, Secretary.

Mar. 11-13.....Milwaukee, Wis., Hippodrome, First Annual Show of Milwaukee Automobile Club.

Mar. 13-20.....Minneapolis, Minn., National Guard Armory, Second Annual Show, Minneapolis Automobile Show Association. F. E. Murphy, Secretary.

Mar. 15-20.....Rochester, N. Y., Convention Hall, Annual Show, Rochester Automobile Dealers' Association. Charles J. Moran, Exhibition Manager.

Mar. 22-27.....Toledo, O., Coliseum, Annual Automobile Show, Toledo Automobile Dealers' Association.

Mar. 27-Apr. 3..Pittsburg, Duquesne Garden, Automobile Show, Pittsburg Automobile Dealers' Association.

Races, Hill-climbs, Etc.

Mar. 5-12.....Palm Beach, Fla., Lake Worth, Fifth Annual Regatta. Palm Beach Power Boat Association.

Mar. 23-26.....Daytona, Fla., Seventh Annual Florida Beach Races, Florida East Coast Automobile Association. New York Representative, W. J. Morgan, Thoroughfare Building.

Mar. 24-27.....Syracuse, N. Y., State Armory, Automobile Show, Syracuse Automobile Dealers' Association.

April 5-10.....New York City, Carnival Week, New York Automobile Trade Association.

April 10.....New York City, Fort George Hill, Second Semi-Annual Hill Climb of New York Automobile Trade Association.

April 27-30.....Detroit, Mich., Four-Day Endurance Run, Detroit Automobile Dealers' Association.

June 11-12.....New York City, Two-Day Mountain Tour and Reliability Contest to Catskill, N. Y., and Return, New York Automobile Trade Association.

Sept. 11-19.....Italy, Bologne, Florio Cup Race, Automobile Club Bologne.

Sept. 19.....Austria, Semmering Hill Climb.

WHAT IS GOING ON IN CLUBDOM'S REALM

BOSTON'S BIG CLUB IS REORGANIZING.

BOSTON, Feb. 20.—If present plans are carried out Boston will have a new motoring organization, larger and stronger than any that now exists. It will be brought about by the amalgamation of the Bay State Automobile Association and the Boston Motor Club, the organization of which was begun a few weeks ago, but has now been halted because of the larger project. Many of the parties interested in the Boston Motor Club are former members of the Bay State. having resigned recently on account of differences of opinion regarding the management of the association.

Realizing that it would be impossible for the Bay State to continue to hold its important position in the motoring world with a diminished membership, and that less could be accomplished for the cause of motoring by two small clubs than by one large one, the directors of the Bay State made overtures to the organizers of the Boston Motor Club looking toward an amalgamation.

The result of these overtures was an agreement between committees of the two clubs to organize a new and third club, which shall include the members of the Bay State and the Boston Motor Club. After the new club is organized the others will go out of existence and the new organization, with a new name to be decided upon later, will occupy the clubrooms of the Bay State Automobile Association. This plan has been ratified by the Boston Motor Club promoters, and it will shortly come before the members of the Bay State. If it is accepted and goes through, it is believed that Boston will have one of the best motoring clubs in the country, and one that will worthily uphold the dignity and prestige of the Hub and the Bay State.

Where the Diners Assembled in the Grillroom of the A. C. A.

NEW HOUSE FOR LONG ISLANDERS.

BROOKLYN, N. Y., Feb. 22.—Fronting on Prospect Park Plaza, at 918 and 920 Union Street, a four-story building, well suited for the needs of automobilists, has been secured for the new clubhouse of the Long Island Automobile Club and will be occupied at an early date, according to a special announcement made by the Board of Governors. The building will easily accommodate 150 cars, with a large elevator for carrying them to the various floors or to the basement for storage, cleaning or to the top floor for repairing. A fully equipped shop is at hand, with all the necessary machinery to enable owners to do their own work, if desired, upon their machines. The clubrooms will be located upon the second floor, with a fine view of the Plaza, and will be arranged and furnished very shortly.

The committees for the ensuing year have been appointed and their chairmen are as follows: Law and Legislation, W. P. Richardson; House and Entertainment, Edwin Melvin; Auditing, J. H. Emanuel; Garage, William Schimpf; Membership, A. C. Alderman; Contest, A. R. Pardington; Technical, Louis T. Weiss; Good Roads, C. J. Edwards.

SCHEME OF ONE CLUB'S ENDURANCE ROUTE.

NORRISTOWN, PA., Feb. 22.—The local automobile club has such a variety of opinions as to the best route for the two-day endurance run it proposes to hold next May that it has adopted a novel scheme to reach a decision. At a smoker in its new clubhouse next Thursday evening, to which all the prominent owners and tradesmen in Norristown, Philadelphia, Lancaster, Reading and other nearby cities have been invited, all will be invited to express their opinions in the matter. That unique organization of Philadelphia automobile writers, "The Shock Absorbers," will come up from Philadelphia.

A. C. A. TO REPEAT DINNER DANCE.

NEW YORK, Feb. 22.—Owing to the very evident success of its first dinner dance, held on the evening of February 17, the Automobile Club of America has decided to repeat the affair in the near future. The attendance of some 160 persons at the first, and their pleasure, was such as to cause the chairman of the entertainment committee, Orrel A. Parker, to announce that similar events will be put upon the programme. At the first one, the first, also, when ladies took a prominent part in a social function held by the club, the dinner was held in the grillroom and was entirely informal, there being no speeches. The dance itself was held in the big ballroom later in the evening, and this arrangement met with universal favor. The second affair is to be held at a date to be announced soon.

DETROIT MAY HAVE ANOTHER CLUB.

DETROIT, Feb. 22.—Detroit is to have a new automobile club, if present plans materialize. The pioneer organization locally is the Detroit Automobile Club. During the Summer, there is always something doing at the Pine Lake clubhouse, thirty miles from Detroit, but in Winter everything lies dormant.

The proposed organization will be built along broader lines, corresponding to similar ones in Buffalo, Cleveland, Rochester and elsewhere. Every automobile owner in Wayne county is eligible, and any motorist outside the county can become an associate member. Headquarters will be established in one of the downtown hotels, club rooms maintained, and the organization, which promises to enter the field with not less than 500 members, will take an active part in framing legislation for motorists and in the advancement of the good roads cause.

ADDITIONS TO PENNSYLVANIA FEDERATION.

PITTSBURG, Feb. 22.—Two new clubs have been added to the Pennsylvania Motor Federation within the past month. They are the Automobile Club of Du Bois, of which J. H. Fulford is secretary, and the Beaver Valley Motor Club, of Beaver Falls, whose secretary is J. A. Snyder.

LEGISLATORS WITH NARROW VISIONS.

Strange things are sometimes said by worthy legislators in the Congress of these United States at Washington. How forcibly has this been impressed upon the public at large recently through the animated discussions as to whether or not the President-elect shall be allowed to ride in comfort in the tonneau of a big touring car or be made to use the old method of horse-drawn transport. Yet it is a fact that the advisability of allowing automobiles to supersede horses in the White House stables was seriously questioned. That has been, at last, permitted, but still the subject of automobiles crops up, and still some of the members of that venerable body, the Senate, are prone to show either narrowness of vision or what little they know by telling all they know.

The present session has been remarkable for the amount of time devoted to the discussions of automobile matters, and it has developed that the automobile has more friends than enemies under the great white dome. The last debate was an interesting one between Senators Tillman and Bailey, occurring when the salary for a District of Columbia official, as a member of an "automobile board," was discussed. Senator Tillman stated that he favored the automobile, but thought that the police should be made more strictly to enforce existing speed regulations. Imagine the answer from Senator Bailey: "I am frank to say that I do not believe there is progress in commercial or political conduct that substitutes factory products for those of the farm. I protest against the government still further accelerating this. * * * It is the intention of the President-elect to discard horses and substitute the automobile, and then everybody will want to imitate the President, thus depriving the farmers of a valuable customer for one of the necessary products of the farm."

Senator Tillman's rebuttal was to the point, saying that his colleague's position was untenable and that he was mistaken in his dread of the effect of automobiles on rural life, without taking into consideration that they are parts of the progress of the world in locomotion.

If Senator Bailey fears that growth of the automobile industry will deaden that of raising horses, it is wondered what he said when gasoline engines were substituted for the old treadmill, or what in answer to the fact that the use of automobiles is taking more real money, in cash and bills, out into the country than any other step in the progress of the nation.

* * *

PRICE OF STEEL HAS SMALL BEARING.

Taking into account the distribution of the several items which enter into the cost of automobiles it is to be noted that steel represents no more than one-tenth of the whole cost, providing the steel used is of the finest grade the market affords. On the face of it, a cut of even 20 per cent. in the price of steel would only amount to 2 per cent. in the cost of a car; hence it is plain that the automobile industry is only passably interested in the present "slash."

In a well-built automobile it is the labor that counts, and it is on the labor that the general expenses must be computed. In a general way the manner of fixing the cost involves items and mode of procedure as follows:

(a) Labor, plus fixed charges.....54 per cent.
(b) Material, plus cost of handling.....16 per cent.
(c) Advertising, selling, delivering.....20 per cent.
(d) Profit to the maker.....10 per cent.

In the item (c) is the profit to the "agency," and in the item (b) is the cost of the accessories as usually furnished by outside makers, thus involving a separate profit.

Even a cursory examination of the situation, taking into account the fact that the steel must be a small proportion of the total cost of a car, leads to a conclusion in which it will be impossible to see wherein a cut in steel can have any material, direct bearing upon the cost of automobiles, unless in the long run competition among the steel makers will result in an enhanced quality of the product, which, however, is a separate question.

What the automobile industry wants is an increased mileage of "good roads." There is the South to "tap"; the wide, wide West is crying to be opened up, and in our own East roads are much wanted. It will be many years before the question of the price of steel will have any substantial bearing upon the situation. In the meantime one good road, say from Atlanta, Ga., to Washington, D. C., would sell more cars than can be turned out in the plant of the greatest producer in the land at the present time in twelve months, under pressure such as would assure a "fat" lighting bill. Plainly, then, the automobile industry is not acutely interested in the price of steel, nor is this to be construed as indicating that "robber" prices should be paid for quality. In the meantime the agitation for good roads should go on because it is the great main question.

A WHITE FOR THE WHITE HOUSE.

NEW YORK, Feb. 22.—Ever since it was learned that autos would be used by the coming Chief Executive of the nation and would supersede the equines in the White House—no longer stables, now to be a garage—there has been considerable competition among the various manufacturers, and G. W. Bennett, Eastern manager of the White Company, is receiving the congratulations of his friends at his success in obtaining an order from President-elect Taft for a White car for his own use. The United States coat of arms is artistically painted on each of the doors, and the color choice is a little unusual, being a harmonious blend of subdued greens. The car has left the factory en route for Washington and will be delivered to the White House some time during the present week. Mr. Taft has been using the White cars in a number of cities he has visited.

The White Company is considerably gratified at the further endorsement by the United States of the White car, as the Eastern branch has recently delivered a White limousine to Gen. J. Franklin Bell, chief of staff, and a Model "M," seven-passenger White touring car to the War Department.

ATLANTA WANTS ROAD FROM WASHINGTON.

ATLANTA, GA., Feb. 22.—A good highway, stretching in a generally direct line of 700 miles, from Atlanta to Washington, D. C., kept up by the several counties in the various States through which the roads would pass, is now the subject of promotion on the part of the Good Roads Club of Georgia. The need of better roads is keenly felt throughout the South, and it is felt that if a good beginning is made that the work will rapidly progress.

The idea is to get each county to round up, roll and ditch one of its existing roads from border to border, and as soon as possible to chart, macadamize or otherwise permanently improve it. This action would give a through route from this city to the national capital, and the roads chosen in each county must be nearly in a direct line with the straight line between the two points. Several of the counties already have fine macadam roads, but it is probable that much of the distance would have the ordinary dirt surface for some time rolled and scraped with the wood drag.

The movement is backed by farmers and autoists alike, and with the co-operation of the organizations in the other States should meet with great success.

E-M-F SELECTED AS GLIDDEN PATHFINDER.

BUFFALO, Feb. 22.—Although the course for the 1909 tour of the American Automobile Association for the Glidden trophy has not as yet been publicly indicated, the first step toward definitely deciding just where the cars will be sent has been the selection of the E-M-F 30 as the official pathfinder for the route of the coming contest. Bids for this privilege were opened on February 16, and the Everitt-Metzger-Flanders Company was the highest bidder, its offer being accepted by the Contest Board of the A. A. A., of which Frank B. Hower, of this city, is chairman.

It is understood that Dai H. Lewis will be sent out earlier than usual this year because the western roads will permit it, but the probable route will not be announced for fear that hotelkeepers and others en route will be influenced to raise their rates.

HOTCHKISS TACKLES HIS HARD JOB.

ALBANY, N. Y., Feb. 18.—William H. Hotchkiss to-day assumed his new duties as State superintendent of insurance, taking the oath of office in the Secretary of State's office. Mr. Hotchkiss is the well-known president of the American Automobile Association, though it is among the possibilities that he may decide to relinquish that position because his new duties will call for most conscientious attention.

Mr. Hotchkiss was elected to the A. A. A. presidency in December last for the third time, and his administration has proven very successful.

A PIERCE-ARROW FOR WHITE HOUSE.

BUFFALO, Feb. 22.—Considerable self-congratulation has been indulged in, in this city, by leading business men during the past four days over the announcement that a Pierce-Arrow car will be included in the equipment of the White House garage, for the use of President-elect Taft and his family. A contract has just been signed by officials of the federal government and the Pierce-Arrow Motor Car Company by which a six-cylinder 48-horsepower suburban car will be delivered at Washington as soon as it can be finished. So far this is the only enclosed car which has been purchased for the use of the chief executive.

The main color of the car will be royal blue, with the door panels a rich russet and a single narrow strip of the same color following the lines of the moulding. Emblazoned upon the doors will be a facsimile of the great seal of the United States. The interior of the machine will be upholstered with blue broadcloth, and the fittings will be in the same style as those used in all Pierce suburban cars. This is true also of the exterior finishings, and it is expected that within a few days the car will be on its way to the White House for use at the inauguration.

PACKARD FOREIGN TOURING PLANS.

PARIS, Feb. 20.—After a brief visit to headquarters at Detroit, Manager H. D. Wilson has just returned to Paris and taken up duties at the new Packard branch at 177 Boulevard Pereire. The new offices of the Packard European touring department are centrally situated within two-minutes' run of the Avenue de la Grande Armée, the automobile avenue of Paris. Manager Wilson declares that arrangements have been made for carrying in stock all necessary parts of new and old models of Packard touring cars; thus any Packard part which may be required while touring in Europe can be forwarded within an hour of receipt of telegram. The call for parts is not great, the sales by no means sufficing to pay the expenses of the office. It is a great convenience to tourists, however, to be able to obtain spares for an American car in Europe, just as quickly as if the car had its home on this side of the Atlantic.

A record number of tourists is expected this year, and the information department has been revised and brought up to date to meet the demands which will doubtless be made upon it.

CARRIAGE CONCERN TURNS TO TRUCKS.

YORK, PA., Feb. 22.—Despite the fact that the York Carriage Company's plant is running overtime on orders for carriages, the company recently closed a contract for a new building, which will be used exclusively for the manufacture of commercial vehicles. This will be 200 feet in length by 50 feet wide and two stories high, but provision will be made for more stories in the future. The building will be of brick and ready for occupancy the first of May. The members of the company are convinced of the growing demand for power vehicles, and, although the carriage works will be continued, the commercial end will be pushed to the limit. Experts have been busy for some time on the design, but the details have not been announced. At the start employment will be given to over 100 men.

TRYING TO REVIVE BROOKLANDS.

LONDON, ENG., Feb. 22.—The first race meeting at the Brooklands track, which has just been announced, will be of interest to Americans because of the new track projected in Indiana, the latter being more or less of a copy of the famous oval.

The race meet announced will last two days and, coming as it does during Easter week, the sixteen events carded are expected to draw well. In the list of events two innovations are noticed, namely, the abandonment of the standard classes and the limit placed upon the stroke of the motor in three of the races. The latter will be watched very closely to see if it will have as much effect upon the industry as did last year's Four Inch Race.

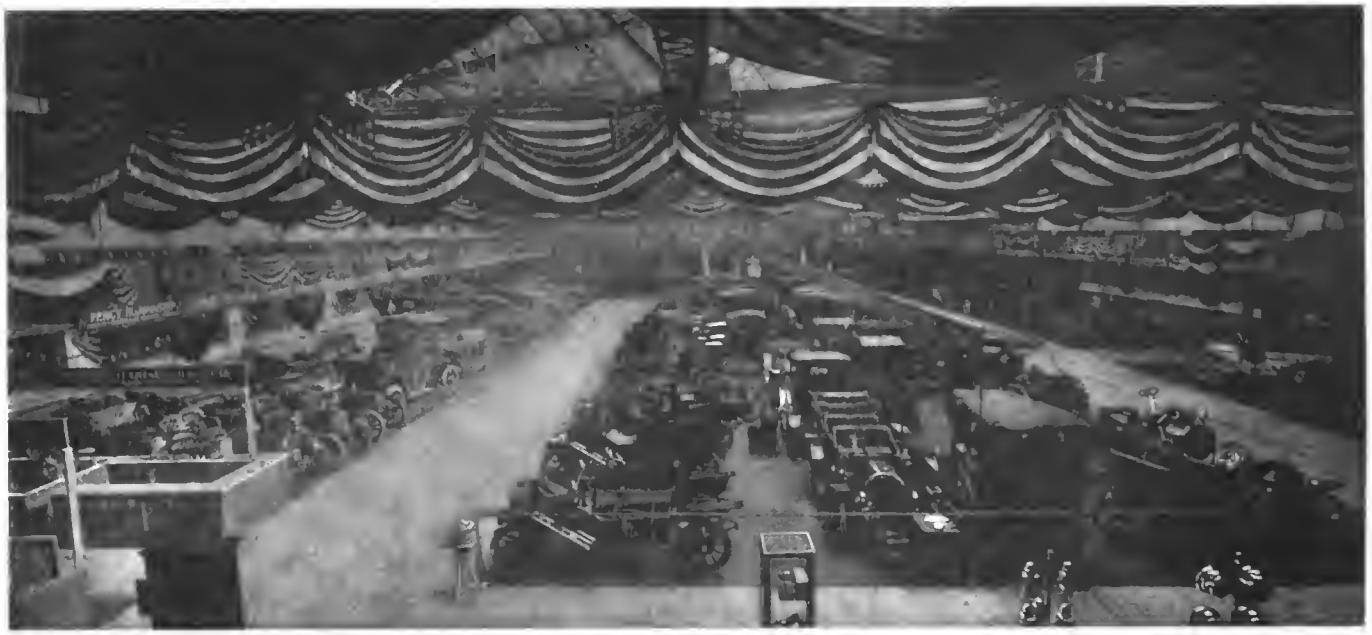
NEW JERSEY'S SHOW IS ATTRACTING THOUSANDS

NEWARK, N. J., Feb. 24.—In the Essex Troop Armory, on Roseville Avenue, what answers as the automobile show of the State of New Jersey most successfully opened on Saturday night, had another bumper crowd on Washington's Birthday and has now settled down to a substantial daily attendance containing interested and willing buyers of cars.

It was George E. Reeve, president of the Newark Board of Trade, who "officially opened" the show in a very apropos speech, which pleasingly contained optimistic facts of the industry.

There are on exhibition some 75 cars, represented by 30 dealers, the list comprising top-notchers and the most reasonably priced cars produced. One new face in metropolitan showing is the Oldsmobile, the Newark agent of which displays, among other models, the latest one listing at $1,200.

The decorations are of a very pleasing but simple nature, consisting principally of bunting, covering the rafters and draping the balcony. In addition, a myriad of American flags, well scattered around, lent a patriotic air, as was very appropriate on Washington's Birthday. The show spaces themselves are the acme of simplicity, gaudy and glittering trappings being conspicuously absent.



Broad, Roomy Aisles, Plenty of Space and Simple Decorations Characterize the Newark Automobile Show.

This show, one of the very best of the smaller local shows, is conducted by the New Jersey Automobile and Motor Club and the New Jersey Automobile Trade Association. The committee in charge consists of George W. Paddock, president, and W. H. Ellis, secretary for the dealers, and Paul E. Heller, president, and H. A. Bonnell for the club. The latter has direct charge of the exhibition as general manager, and considerable credit is due to him and his capable assistants for their able efforts, which resulted in the work being completed so that the exposition was not only finished, but also opened on time, often unusual in the automobile show realm, and as pleasing as unusual.

Although spoken of as the second annual exhibition, this actually is the third that has been held. The first of these, however, was not an exclusive show, but simply a corner of a sportsman's display given up to a few automobiles. It is well to mention right here that the tail wagged the dog, so to speak, in that this little corner attracted more attention than the rest of the exposition. Since then the show has been a separate as well as an annual affair, held in a separate building.

Considerable attention is given to the medium-priced cars, thus reflecting the modern tendency. Although the few larger and consequently higher priced machines attract their quota of people, the smaller cars are in the majority as far as mere numbers are concerned. Of these, in turn, by far the greater number come in the so-called "$1,500 class," which would include all those listing at between $1,250 and $1,750.

The steam division is monopolized, as usual, by the White Company, which has one of the most prominent spaces as well as one of the largest. Here three of the latest model steamers receive much attention.

The Ellis Motor Car Company, the Pierce-Arrow agents in Newark, have the only car enclosed by a railing. This is one of the smaller Pierce-Arrow sizes, with a natty runabout body.

Motorcycles are not on view in any great quantity, owing to the smallness of the space available for them, but the few shown win enough notice to more than make up for this. The growing popularity of this form of motive power, shown so plainly at other shows, is in evidence here, and each one of the few exhibitors is surrounded by a small but enthusiastic crowd at all times.

While the throng present at the opening was mostly a curious one, subsequently a great deal of serious business was done, so that all of the exhibitors exprcss themselves as very well pleased with the amount of business being transacted, both on the opening night and thereafter. Many sales are being made, one peculiar fact about the first sale of the show being that it came at 4 o'clock in the afternoon, about three hours before the show actually opened. Thereafter sales followed steadily, and the demonstrating cars outside were kept busy at all times.

One feature of the show is the moving picture exhibit. Promptly at 10 o'clock the lights are turned out and an excellent series of pictures shown, including the Vanderbilt Cup, Savannah Grand Prize and other famous races.

The attendance has been excellent thus far, and, aided by special night programs on Wednesday, Thursday and Friday, the show bids fair to make a record that future shows may try for.

Several very important meetings are scheduled for the Thursday "club" night, when legislative and other important matters will be discussed by representatives of the Associated Automobile Clubs of New Jersey.

One of the exhibits attracting much attention is that of the Rickey Machine Company, East Orange, N. J., which is now directed by Mrs. Rickey, who has successfully continued the business since her husband was killed over a year ago in an automobile accident. Mrs. Rickey is thoroughly competent mechanically, and she has effected the sale of many Marmon cars in Newark and the surrounding country.

Herewith is the list of car exhibitors:

Acme—Cordner, Flinn & Toppin, 76th street and B'way, New York.
Brush—Brush-McLaren Motor Co., 47 William street, Newark.
Cadillac—Motor Car Co. of N. J., 291 Halsey street, Newark.
Chalmers-Detroit—Paddock-Zusi Motor Car Co., 215 Clinton avenue, Newark.
Crawford—Mitchell Automobile Co., 282 Halsey street, Newark.
E. M. F. (30)—H. J. Koehler Sporting Goods Co., 845 Broad street, Newark.
Ford—Essex Auto Co., Inc., 518 Broad street, Newark.
Fiat—Fiat Automobile Co., F. L. Apgar, Manager, Newark.
Grout—P. H. Johnston, 9-11 Hill street, Newark.
Isotta-Fraschini—J. M. Quinby & Co., 21-39 Division street, Newark.
Jackson—Essex Auto Co., Inc., 518 Broad street, Newark.
Kissel-Kar—Weldon & Bauer Co., 200-202 Halsey street, Newark.
Locomobile—The Green Motor Car Co., 90 Washington street, Newark.
Marmon—Rickey Machine Co., 92 Eaton place, East Orange.
Maxwell—J. W. Mason, 350-352 Halsey street, Newark.
Middleby—Middleby Auto Co. of N. J., 457 Washington street, Newark.
Mitchell—Martin Auto Co., 284 Halsey street, Newark.
National—Weldon & Bauer Co., 200-202 Halsey street, Newark.
Oldsmobile—Oldsmobile Co. of New York, 88 Washington street, Newark.
Overland—Overland Motor Car Co. of N. J., 16 Railroad place, East Orange.
Peerless—Carl H. Page & Co., 237 Halsey street, Newark.
Pennsylvania—J. M. Quinby & Co., 21-39 Division street, Newark.
Pierce-Arrow—Ellis Motor Car Co., 124-126 Washington street, Newark.
Premier—O'Neil Motor Car Co., 55 Bank street, Newark.
Rambler—Rambler Automobile Co. of New Jersey, Newark.
Regal—P. H. Johnston, 9-11 Hill street, Newark.
Reo—O'Neil Motor Car Co., 55 Bank street, Newark.
Stevens-Duryea—A. G. Spalding & Bros., 29 West 42d street, New York.
Stoddard-Dayton—Atlantic M. C. Co. of N. J., 228-230 Halsey street, Newark.
White Steamer—The White Co., 494 Main street, East Orange.

NEW YORK CARNIVAL PLANS MATURING.

Marked progress in the plans for the annual automobile carnival of the New York Automobile Trade Association, has been the result of active work during the past week of the committee in charge and the liberal support of the trade, financially as well as otherwise, has been secured. There was less of the preliminary work to be done this year because the ideas are generally understood and appreciated. Subscriptions to the fund for covering expenses have been in order and a number have been received, enough to show that the tradesmen are going to stand back of the committee. Further meetings of the committee will be held at short intervals until the festive week arrives, when all subjects of importance will be considered, to insure readiness at the proper time.

The increase of registration of automobiles at Albany after the festivities of last Spring has been considered as a conclusive proof of the value of such an event to stimulate interest not only in the city but also in the surrounding country and the consequent sale of cars. This is shown by figures secured from Albany, where previous to the 1908 carnival there had been a large decrease in the number of autos registered each month over that of the same months in 1907. After the carnival the increase is shown in figures which have spoken for themselves.

Month.	1907.	1908.	Increase or Decrease.
January	547	497	50 decrease
February	501	396	105 decrease
March	1,138	992	146 decrease
April	2,147	1,785	362 decrease
May	2,160	2,102	58 decrease
June	1,963	2,398	435 increase
July	1,662	1,868	206 increase
August	1,176	1,400	224 increase
September	907	1,313	406 increase
October	799	1,118	319 increase
November	600	761	161 increase
December	367	783	415 increase

What a Famous Sculptor Conceived to Represent "The Spirit of Motoring."

This artistic effort, at the entrance to the Detroit Automobile Show, was set agsinst a black background, and brilliantly illuminated. It is a work of art by Sculptor Wagner, and attracted so much attention that it is to be modeled in wax by the artist, and reproduced in gold by the Detroit newspapers and offered as a trophy for reliability contests.

FROM WHICH CAME "THE SPIRIT OF MOTORING"

By E. LE ROY PELLETIER.

DETROIT, Feb. 20.—When Sculptor Wagner, at the suggestion of the writer, essayed to model a group to typify "The Spirit of Motoring" he had little else on which to base a conception than the bare title. It was but natural therefore that the artist should fall into the common error of believing that the racing river—the sporting side of motoring—was typical of the industry. So, in his first miniature clay model the central figure was a racing chauffeur—low browed—the type of fellow who as a factory tester exhibits certain "dare devil" qualities, and as a consequence is given a chance at a race of greater or less importance. The kind of man who risks his life—because it is the only thing worth while he has to risk. It is his one chance to rise from the obscurity to which, save for accident, he is destined. If he wins he will be famous—fleeting though the fame may be. If he loses—well, he is still a $3-a-day mechanic.

It wasn't Wagner's fault entirely that he had accepted this type of person as the personification of motoring. Every artist who has furnished figures for automobile shows has made the same mistake. I had given Wagner but a faint idea of what was in my own mind—and that idea was very faint in itself. Besides, an artist of Wagner's reputation and standing could hardly be expected to take so brief an event as a one-week automobile show very seriously. I felt sure the assignment was more or less of a joke to him.

But, artist like, he was visibly hurt and indignant when, on seeing his first model, I exclaimed, "Oh, no—no—that won't do at all." Then seeing I had been too brash, I continued in a milder tone, "It wasn't a racing driver I had in mind; not a figure steering a car, but one who is directing the destinies of an industry."

"Industry?" exclaimed Wagner. "Why, then, the idea of speed?"

"Because the automobile industry is the highest speed industry, the most spectacular commercial proposition the world has ever seen. Fortunes are made in a year—or lost as quickly. The failures are due to incompetence, but the successes are not accidental. Let this group represent something more serious; something of vastly greater consequence than all the dare devil drivers in the world."

Wagner had already modeled various types of drivers—all excellent. Supporting the upper basin of the fountain were heads typical of the foreign drivers, who, seated round a table, four or five of them together, the night before a race, each wagers with the others that he will be killed on the following day. The wagers constitute a pot which, in the event of one of the party being killed, will go to his widow or family. On the bases of the columns he had given us another type of driver—the type whose skill consists of a certain negative appreciation of the dangers he risks—who has a meteoric career of a season and ends a heap of broken bones in a hospital—or just ends.

"Detroit is the center of the world of motordom," I continued. It became so, not by chance, but because there happened to be here certain men of wonderful manufacturing and commercial ability—men who could drive a business at a terrific speed, keeping always just ahead of a demand that was mushroom like in growth, yet never dare devil, never for a moment reckless or taking undue chances, though to the uninitiated wayfarer it might appear so. Our character has a firm grip on the wheel; on his brow sets intelligence; his eye is so clear that it sees farther into the future than most, and he is ready for anything that may appear in the road beyond the next blind turn. It may be a strike in the factory; or a financial panic such as a year ago cancelled thousands of orders. Overworking his capital to expand his young business, he yet must convince his bankers that he is steering a safe course. He must have speed, else would he soon be outstripped by his competitors in their chariots racing for fortune. But he drives not so much with daring as determination; steers not so much with his hands as with his head. The type of character I have in mind is——"

"Enough! I have it—I have it!" exclaimed the artist as one inspired. Grasping the miniature model he had formed, he dashed it into the mass of moist clay at his feet and feverishly began to model, as a child makes mud pies, another, the original of the group which has been so much admired during the week.

From that moment Wagner worked, not for his stipend, but for the love of the work. He is a true artist and he had an inspiration. It is from such material masterpieces are made. And it is not too much to say that this is a masterpiece. Destined originally for a brief life of six days, the group has created so much comment and been so highly commended by eminent authorities that the Publishers' Association of Detroit has decreed that it shall not perish with the show, but that Wagner shall reproduce it in miniature in the form of a gold trophy to be presented to the Detroit Auto Dealers' Association for their next reliability contest.

CONNECTICUT'S SHOW HELD IN HARTFORD

HARTFORD, CONN., Feb. 22.—Housed in the Armory of the First Company of the Governor's Foot Guard, with more brilliant and lavish decorations than ever before as a setting, strings of electric lights that throw a pleasing glow over the great hall, an electric fountain which spurts tiny jets of perfumed water into the air, and with all arrangements so completed that it was a perfected exhibition when it was ready to open, the second annual automobile show of the Hartford Automobile Dealers' Association was begun here on last Saturday evening, with twenty-three makes of automobiles, represented by thirteen different exhibitors.

When at 8 o'clock on that evening the doors were thrown wide, there had already gathered a large crowd, and when the interior was seen it was the general opinion that the promise of the show committee, F. W. Dart, S. A. Miner and E. G. Biddle, that it would give an event of which Hartford might be proud, had been lived up to, and this city feels that it has an attraction worthy of a metropolis.

The showing of cars is excellent and, considering the available space, very good use has been made of it. In fact, the same cars could be well displayed in a hall three times as large. Some of the best cars of the country are here gathered and the exhibition is representative. A few newcomers make their initial bow to the public and all, save for two or three, are shown on the ground floor and the stage. A large aisle runs through the center of the hall. To the right on entering is the exhibit of the Miner Garage Company, with the Pierce-Arrow, Knox and Buick. The Knox is shown in two models, a red runabout and a silver gray touring car. The Pierce is also well displayed. On the opposite side of the aisle is the Mitchell exhibit, with the battered winner of the Hartford to Pittsfield endurance run of a few weeks ago. A runabout and two touring models are displayed. In the basement is another car of the same make fitted with a 'bus body for the Allyn House. The Thomas Flyer rubs elbows with the Mitchell and is present in several natty models in fours and sixes. A feature of the Thomas contingent is the six-seventy model, the largest in the show. The Thomas, Oldsmobile, Waverly electric, E-M-F and White steamer are shown by the Palace Auto Station Company.

Across the aisle the Packard 30 is shown in touring, landaulet and runabout types, natty and trim and much admired. Brown, Thomson & Company display the Packards as well as the Cadillacs and Stevens-Duryea. The Cadillac 30 polished chassis is a great drawing card. The Stevens models of fours and sixes are shown to good advantage. The Packard, Stevens and Cadillac exhibit is one of the most comprehensive of the show. Opposite the dark blue Packard 30 runabout is the low-hung American road in its glistening coat of white paint. This is the first appearance of the American, shown with the Maxwell and Stoddard-Dayton by R. D. & C. O. Britton. The Maxwell is shown in the $500 models as well as larger powers, and the setting is very effective. The Stoddard-Dayton looks classy, and the crowd looks it over thoroughly. On the elevated stage the Ford is shown in two models.

The Display of the Hartford Automobile Dealers' Association Had an Effective Setting in the Foot Guard Armory.

At the other end of the stage are shown two Overland runabouts. The Overland is popular in this city, and the local representative has sold many. To the right of the main entrance, in a side room by itself, is the Rambler exhibit. Two models are shown, and the Rambler in its short stay has become known as the car with the spare wheel. C. P. Rockwell and W. J. Wall, of the Boston branch, are at the show. The Rambler is not at present represented in this city. To the left of the entrance, adjoining the Mitchell space, is that of the two-cycle Elmore, a car which is becoming more favorably known each season here. Three models are shown, including a landaulet. In a room off the main hall the Franklin is shown in three models, the sole air-cooler here and a make that has many admirers. In the basement the Stanley steamer runabout is shown by W. J. Hickmott, Jr. This and the White are the only steam models shown. There are many steam enthusiasts in this city at this time, and naturally they look to cars of this class when they enter the hall. The White is shown in a touring model painted a dark red, with a big, roomy body. The Jackson is shown in two models by A. E. Lazarro, for the first time in this locality.

A new car of local manufacture, the McCue-Hartford, is shown in a runabout model, and it looks to be a proposition that would have to be reckoned with on the road. The Jewel, another newcomer, is shown by J. A. Wood in two models, Stanhopes. The Simplex and Palmer and Singer were to have been shown by T. Dudley Riggs, but unfortunately Mr. Riggs could not secure his cars in time for the exhibition. The Atlas was to have been shown, but was unable to get cars through in time.

The show will continue until next Saturday evening. On Thursday evening the Dealers' Association will hold a banquet at the Allyn House at which Governor Lilley and Mayor Hooker are expected to be present. This is the list of exhibitors:

Palace Automobile Station Company, Thomas Flyer, Oldsmobile, E.-M.-F., White Steamer and Waverly Electric.
Miner Garage Company, Pierce Arrow, Knox and Buick.
R. D. & C. O. Britton, American Roadster, Maxwell and Stoddard-Dayton.
Brown, Thomas & Co., Packard, Stevens-Duryea, Cadillac.
Capitol City Auto Company, Mitchell.
Dunbar & Mansir, Elmore.
Elmer Automobile Company, Ford.
W. J. Hickmott, Jr., Stanley Steamer.
Thomas B. Jeffery & Company, Boston, Rambler.
McCue Company, McCue-Hartford.
A. W. Peard, Overland.
J. A. Wood, Jewel.
A. E. Lazarro, Jackson.

Ætna Life Insurance Company, liability insurance.
Travelers' Insurance Company, liability insurance.
Alling Rubber Company, tires, tubes, etc.
Fairbanks Company, marine motors.
A. L. Foster & Company, motoring apparel.
The G. W. Fuller Company, trunks, bags and trunk racks.
Hartford Auto Parts Company, auto parts.
Hartford Mill Supply Company, supplies.
Hartford Times.
George S. Masten, Indian motorcycles.
Perfection Wrench Company, wrenches.
James Pullar & Company, motor-car metal and wood bodies.
Post & Lester Company, tires, tubes and accessories.
Tracey, Robinson & Williams Company, marine motor supplies.
Smith, Worthington Company, motoring accessories.

BUFFALO SHOW WILL BE ELECTRICALLY BRILLIANT

BUFFALO, Feb. 22.—Buffalo's automobile show, which will open March 2 and continue for a week, promises to eclipse anything of the kind ever attempted before in this city. It will be the first show given exclusively under the auspices of the Automobile Club of Buffalo and may be the last so conducted, since W. C. Jaynes, president of the local trade association, has hired Convention Hall for another year with the avowed object of holding next year's show under the auspices of the association. And since it is admitted that there is not room for two shows, the Automobile Club knows that there will be opposition to its conducting the 1910 exhibition.

The determination to make the coming one excel everything before, and worthy of the largest club of resident members of the A. A. A., has stimulated the management to produce results. The decorations are the most elaborate ever attempted in the city, scarlet and gold being the dominant colors. The hall will be illuminated with 5,000 incandescent lamps in the ceiling, divided into twelve squares. Lack of space will limit the show to about one-third of the exhibitors who applied.

The list of exhibitors numbers 40 and includes the following: Centaur Motor Company, Austin Lyman Company, Fargo Electric Carriage Company, Meyer's Carriage & Wagon Company, Brunn & Company, The George N. Pierce Company, John W. Frey, Kane Motor Supply Company, Louis Emgel, Jr., Ralph E. Brown Motor Car Company, Brunn Carriage Manufacturing Company, W. R. Densmore, J. A. Cramer, F. G. Crone, C. H. Bicalky, Knoll & Tuereon, C. E. Miller, Theo. P. Meinhard, F. Z. Phelps, E. H. McCormack & Sons, Harry P. Brainard, American Motor Truck Company, Leo Wertheimer, Poppenberg Motor Car Company, E. E. Denniston & Company, Maxwell-Briscoe Buffalo Company, Frank C. Garvin, Dixon Bros., Iroquois Rubber Company, E. R. Thomas Motor Company, Buick Motor Company, Mason B. Hatch, Buffalo Automobile Garage, Buffalo Automobile Exchange, Babcock Electric Carriage Company, Co-Operative Motor Car Company, National Welding & Manufacturing Company, Jaynes Auto Supply Company, Class Journal Company, H. D. Taylor & Company, W. F. Polson.

SYRACUSE PLANS AN AUTO SHOW IN MARCH

SYRACUSE, N. Y., Feb. 22.—Preparation for an automobile show to be held during the last week in March, probably under the active guidance of Dai Lewis, of Buffalo, is the result of the formation in this city last week of the Syracuse Automobile Dealers' Association and a number of meetings which have been held to consider matters of local importance.

Opening on Wednesday, March 24, and continuing until Saturday evening, in the State Armory, with space available for all local dealers and any others in the western part of the State, is the plan which has been decided upon. Mr. Lewis has been invited to come to Syracuse to take charge of the arrangements after he has finished with the Buffalo affair.

The trade association has been formed to hold several annual automobile events—the show, a hill climb, an endurance run, and some races on the Fair Grounds track, in addition to giving an organization which will endeavor to aid auto affairs in all lines of activity. The officers as elected are: President, C. Arthur Benjamin; vice-president, H. D. Van Brunt; secretary, M. W. Kerr; treasurer, H. L. Conde, and C. H. Norris to act as a fifth member in forming an executive committee.

The charter members are: M. W. Kerr, Buick; C. A. Benjamin, Packard and E-M-F; H. D. Van Brunt, Oldsmobile; Genesee Motor Car Company; Taxicab Garage Company; Amos-Pierce Company; Leon Coude, Brush; and George Wilcox, Mora.

CLEVELAND'S SHOW IS A RIOT OF COLOR

CLEVELAND, Feb. 22.—The 1909 automobile season opened in this city to-night, when the seventh annual show made its bow to the citizens of Northern Ohio. Yet one building being unable to hold all the machines, the Locomobile, Babcock electric and Regal representatives are giving an overflow show in the Hollenden Hotel, while the Mora, Reo, Premier and Overland people are holding private shows in their own salesrooms.

The Central Armory, where the show is being held, is dressed in a manner never before attempted. A riot of color greets the eye, for the general effect is that of an Italian garden, with thousands of flowers twined here, there and everywhere. Bowers of roses, illuminated with colored incandescents, are on every side, with a faint aroma of natural flowers scenting the air. At each end of the huge building is an electric fountain, where water plays over hundreds of lights, constantly changing their color. A huge searchlight flashes forth from each corner of the building, shifting back and forth, picking out brilliant dashes of color. The effect produced is something unrivalled in automobile shows in this country. Whether it is not too elaborate is another question, but at any rate the decorations have caused so much stir locally that the attendance bids fair to exceed that of any previous year by many thousands for the week. A few of the exhibitors claim that the attention of the crowd will be paid principally to the beauty of the show and not to the machines.

Cleveland is one of the best retail fields in the country, and local tradesmen are hustling for business this year as never before. Many purchasers have held off giving their final order until the show, while many buyers from nearby towns come into the city with the agents to make final decisions. Considerable business in the moderate-priced car class is done by the State representatives, so that the Cleveland show is something more than a mere local exhibition.

There are many new cars in the local field this year, the increase being more than usual. Among others, the Babcock electric, Locomobile, Pierce-Arrow, Woods, Waverly and Detroit electrics, the Regal, Pope-Toledo, American Simplex, Midland, E-M-F and Cameron made their formal début this week, while it is expected that one or two other agencies will be placed during show week. One of the features of the show is the large number of electrics shown. Not all could secure space at the show proper, so private exhibitions are very common. Cleveland ranks as the leading city in the country for electrics, and it is not surprising to see a great influx of these graceful cars. There are now eight makes sold here, namely, the Baker, Rauch & Lang, Broc, Columbus, Babcock, Woods, Waverly and Detroit. The first three are manufactured in this city. All except the Woods and Babcock are being exhibited at the show, the others in their own salesrooms.

The following is the list of the exhibitors:

The Auto Shop Co.	Thomas and Selden.
Buick Motor Co.	Buick.
Barger Automobile Co.	Cadillac.
Broc Carriage & Wagon Co.	Broc electric.
Cameron Auto Co.	Cameron.
Commercial Car Co.	Pope-Toledo.
Chisholm & Phillips Auto. Co.	Stevens-Duryea.
Crawford Motor Co.	Jackson.
Detroit Electric Co.	Detroit electric
Elmore Motor Car Co.	Elmore and Waverley electric.
Ford Motor Co.	Ford.
Gaeth Automobile Co.	Gaeth.
Hall Bros.	Cartercar and Plymouth.
Lucas & Christenson.	Mitchell.
Jewel Motor Car Co.	Jewel.
Harry S. Moore..	Stoddard-Dayton and Brush.
Maxwell-Briscoe Motor Co.	Maxwell.
Oldsmobile Co.	Oldsmobile.
Peerless Motor Car Co.	Peerless.
Pullman Motor Car Co.	Pullman.
Price Bros. Carriage Co.	Baker electric.
Reese Motor Car Co.	Royal, Corbin, and Columbus electric.
Rambler Automobile Co.	Rambler.
Rauch & Lang Carriage Co.	Rauch & Lang electric.
Standard Automobile Co.	Packard and Franklin.
Studebaker Automobile Co.	Studebaker and E-M-F.
Charles B. Shanks Co.	Chalmers-Detroit and Stearns.
Winton Motor Car Co.	Winton.
Wingle Motor Car Co.	American Simplex and Midland.
The White Co.	White.

In the local retail trade a number of new agencies have been placed. The Western Reserve Motor Car Company was organized to handle the Pierce-Arrow, Knox and Woods electric. The Elmore Motor Car Company has taken the Waverly electric agency; Stahl, Hoffman & Company that of the Locomobile; the Commercial Motor Car Company to sell Pope-Toledo, and the Wingle Motor Car Company to sell the American Simplex and the Midland.

BIG FRENCH MAKERS WILL OPPOSE ANNUAL SHOW

PARIS, Feb. 20.—French constructors, or at any rate, the élite of them, are opposed to an annual automobile exhibition. The Automobile Club, the small constructors, tire makers, accessory manufacturers and dealers are in favor of continuing the show in the Grand Palais. Hence, if not exactly a war, at any rate a state of dispute. With the object of strengthening their position, the anti-show men recently visited London to attempt to convince John Bull that his Olympia show was a vain thing and should either be abolished altogether or held on every other year, alternating with the necessary evil in Paris. But automobile John Bull has an idea that if the Paris Salon were abolished London would become the motor mart of Europe, and while he sympathized with the Frenchman, he gave him no hope whatever that his show would be closed down.

In face of this set-back the French constructors conferred and came to the decision that not only would they still oppose the Paris Salon, but they would band themselves into an association sacred to big, anti-show constructors, where it would be impossible for the tire potentates and host of accessory men to outvote them.

The situation at present is, therefore, that 60 per cent. of the French constructors, comprising all the large world-famed firms, are opposed to sending any of their products to the Grand Palais; the club, backed up by small makers and accessory interests, is determined to continue a display that has always been a source of profit. The club will go ahead with its show, which will doubtless be held at the end of November and the beginning of December, in the Grand Palais. Deprived of the big constructors, they will admit aeroplane and dirigible balloon manufacturers, motor boats, commercial vehicles, cycles and all accessories.

A mixed show of this nature can be made a success, though of course it will have nothing of the éclat of some previous exhibitions. The aeroplane section alone is sufficiently powerful to fill nearly one-half the hall, and the rest of the space will be none too large for the automobiles, accessories, etc., which will ask admittance. Probably, in view of the determination of the club to hold the Salon despite the opposition of the big makers, these latter will be obliged to climb down and ask to be taken in also. It is practically certain that a certain number of them will break away if the show is persisted in, for the bond under which they have placed themselves is not one that is likely to be upheld by law.

It is interesting to note that the anti-show group is also the anti-racing party; but, while the big manufacturers monopolize the Racing Board, they only form a fraction of the club committee dealing with the Salon, and are also in a minority on the Manufacturers' Association, which unites with the club for the holding of the show. This explains why, after killing the Grand Prix with the utmost ease, it is somewhat difficult to stifle the annual Salon.

DENVER HAD A BIG SHOW SUCCESS

DENVER, Feb. 22.—In the great Auditorium, large enough to hold the biggest conventions and giving space for over 150 automobiles, for three days of last week, Tuesday, Wednesday and Thursday, Denver's annual automobile show was held under the most auspicious circumstances, both from viewpoints of attendance and the general interest worked up through the city and surrounding country by it. This year marked the entrance of the Denver Motor Club into the field as a promoter of an automobile exhibition, and those who participated by having exhibits or by attending gave voice to opinion that the event was surely a great success.

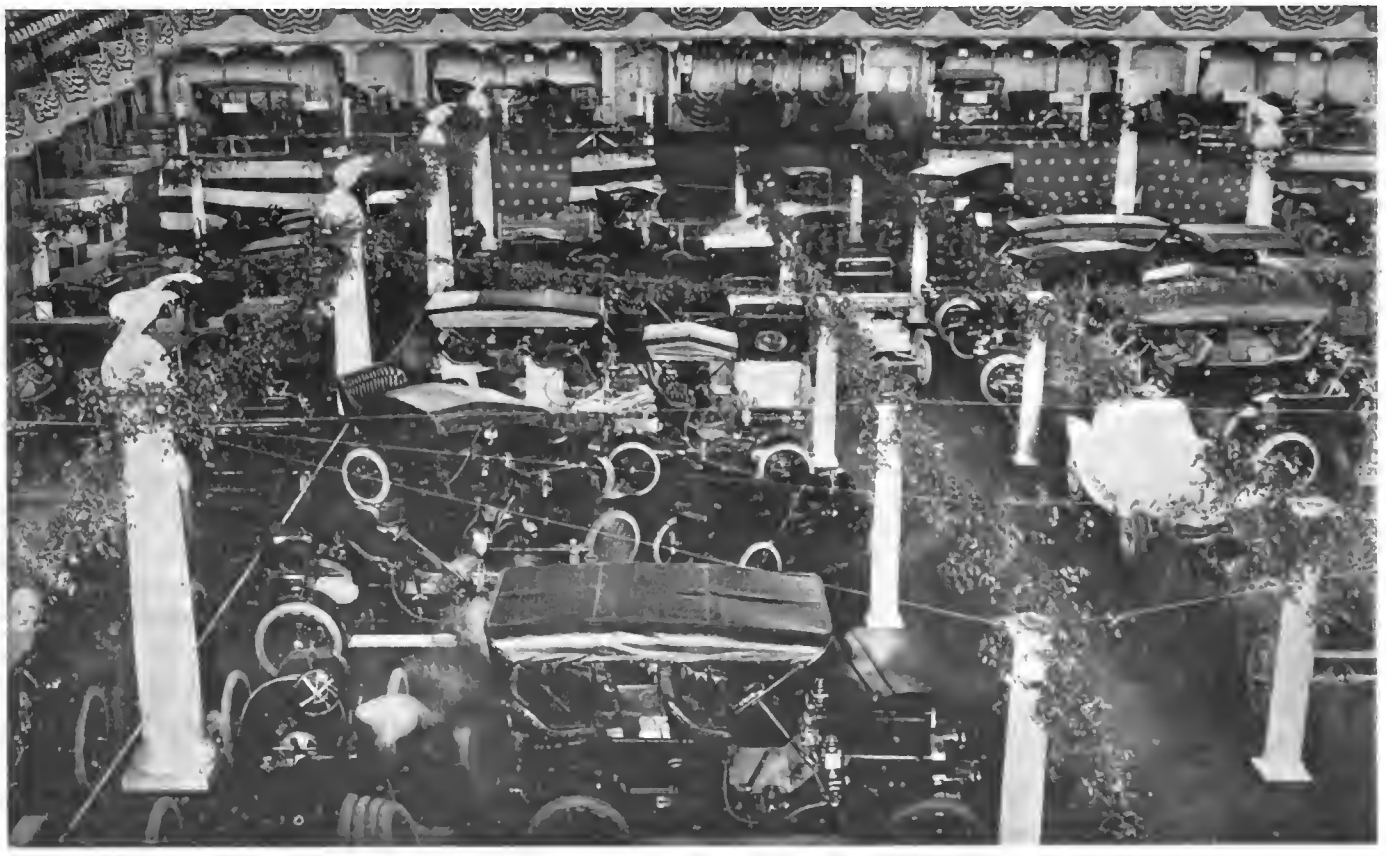
Of the 56 exhibitors, 27 were dealers in automobiles, while the remaining ones handled accessories or special exhibits. One hundred and fifty cars were on the floor and represented 39 different makes. Fifteen thousand square feet of floor space was available for use in the main section, and a hallway, extending around the entire building, and 15 feet wide, gave additional room, not only for exhibitors, but also for a wide aisle.

A beautiful decorative scheme was worked out by Denver artists, so that the whole building was transformed into a bower of novel and striking nature, forming a gorgeous setting for the big and little cars and making a contrast between the beautiful colors more pronounced. A prominent band gave concerts in the afternoons and evenings, with soloists to lend additional interest.

On entering the big hall the passageways took the visitors first through the boxes, where were accessory exhibits, and then out into the main hall itself. At the right of the entrance were the models of the new Reo cars, both single and double cylinders, fitted with runabout and touring bodies, and on the left was the space containing the Oakland and the Kissel Kar. In the same tier, at the right and beyond the Reo, were the Dorris and Frayer-Miller, and at the right the Moon and Rauch & Lang Electric.

Proceeding to the center aisle, on the left was the Cadillac and opposite it the Fritchle electric, then the Ford, the Packard, the Maxwell, Buick and others. The whole floor was divided into two sizes of spaces, a large and a small, the large ones being taken to show the Mitchell, Rambler, Stevens-Duryea, Pierce, Chalmers-Detroit, Jackson, Matheson, Stoddard-Dayton, Cadillac, Studebaker and E-M-F, and the Thomas, Oldsmobile and Columbus electric. Smaller spaces were occupied by the Velie, Welch, Colburn, Maxwell, Apperson, Packard, Buick, Overland, Baker, Ford and Fritchle representatives.

The Studebaker Company was the only one showing a commercial vehicle. In an annex there were shown the White, Midland, Speedwell, Sterling, Model and Victor. A number of motorcycles were shown by local dealers, while among the accessories shown were articles for every conceivable want of an autoist.



Denver's Great Auditorium Supplied a Commodious Building for the Motor Club's First Show.

Social events marked the week of the show, banquets and smokers being held by club members, some of which were booster meetings for the show. These made the affair almost a social and society event and added greatly to the success attendant upon it.

The Denver Aero Club prepared a special exhibit, the huge tube for the Cage aeroplane being completed in time to have it suspended from the dome of the Auditorium, overhanging the main floor, so that it was seen from all parts of the house. On Thursday evening, the final session of the show, an airship flight was made by George Uber, a Denver engineer, with an airship of his own invention. Denver claims the distinction of having the largest number of automobiles in proportion to its population of all the cities of the country.

FOLLOWING a custom in the best regulated households, coupled with the opening of a number of new buildings and the vacating of others, spring house cleaning along the metropolitan automobile row this year has accounted for a number of changes in location, in equipment and in general appearances. There has been a tendency toward moving uptown along Broadway or of taking up quarters on intersecting streets just off the main thoroughfare, and as it is still early in the extensive selling season it is to be expected that still more alterations in the row will happen later.

An important cause of a number of removals has been the opening of a large, splendidly planned building erected just for the automobile business on the block extending from Sixty-fourth to Sixty-fifth Streets, on Broadway, with all manner of conveniences for the successful handling of the trade, and as soon as it was opened a number of concerns took up space there. This at the same time emptied a number of other places lower down the row and other concerns moved in to fill the vacancies.

Still another building was opened at Sixty-eighth and Broadway and was promptly occupied by automobile agencies and the general trade. Both these new buildings are suitable for the use to which they have been put, especially the large one lower down the row. It was so built that there are entrances for cars on both of the numbered streets, and a runway extends through at the rear of the offices and show rooms, with large sliding door entrances to them. Two big elevators carry the machines to upper floors, where practically the same plan has been carried out of having the various sales rooms connected by a wide hallway. Passenger elevators are in the front of the building for use in reaching the upper floors.

One of the first concerns to take rooms in this structure was the Maxwell-Briscoe Company, under the direction of Col. K. C. Pardee, which took the two large quarters on the first floor at the upper corner, so that there is room for offices, plenty for show space and a large room for storing new cars for delivery or for use as a garage for the demonstrating cars of the company. Col. Pardee has already moved in from his former location on West Fifty-ninth, near Columbus Circle. The official numbers of the Maxwell branch are 1930 and 1932 Broadway, and as yet no one has engaged the vacated building. When the importers of the C. G. V., in short for Charron, Girardot et Voigt, moved into the building, taking office rooms on the first floor at the Sixty-fourth Street side, and with nearly the whole fifth floor for show, garage and storage purposes, they vacated their former offices between Sixtieth and Sixty-first, and the Morgan & Wright branch took that. The C. G. V. cars are for a time being shown in the corner room of the first floor, but this is only temporary.

Under the management of George Jordan, the Cameron Car Company's branch was opened at No. 1928, just above the entrance to the passenger elevator hallway and next to the Maxwell branch, in a large, rectangular-shaped room. On the other, lower, side of the elevators the Atlas branch took a position, under the management of L. F. Johnson, having moved from No. 1876 Broadway, and now having headquarters similar to those of the Cameron. Both are well and favorably located.

Since the Grand Central Palace show the National cars have been represented in this city by a direct factory branch, with W. C. Toertner as manager, and headquarters were taken at No. 1922, near the Sixty-fourth Street side of the new structure. A number of the newest models of this Indianapolis concern are in the show rooms. On one of the upper floors the Allen Auto Specialty Company is located, completing the list of the present occupants of the building, but it is well understood that as there is considerable room still available a number of the tradesmen are looking at space both on the ground and upper floors. The site is good, and the vacancies will be rapidly filled.

Further up the row, at Sixty-eighth, Harry S. Houpt is about to open his show room and offices for the sale of the Herreshoff, and later the Houpt cars, but pending alterations the cars are being shown in the Hotel Marie Antoinctte and the offices are divided between Mr. Houpt's headquarters for the sale of Thomas cars and the new office space. With him in this building are the recently opened factory branch of the Speedwell Motor Car Company, with John Tugby as manager, and the selling branch for Dow tire tubes.

Previous to the move of the C. G. V. Import Company and the subsequent transfer of the Morgan & Wright tire makers' branch to the former C. G. V. place of business at 1849 Broadway, these tires had been represented in a building a few doors off Broadway, on Forty-seventh street, but the necessity for more space required that a change be made and the branch was moved further uptown.

Of distinct importance will be the change soon to be made by the Lozier Motor Company, which, although it moves but a block, will have a building of its own and nearly four or five times as much space as it now occupies. At present it is located at the corner of Fifty-fifth Street and Broadway, in a building which is large, but so subdivided that the Lozier interests get but a small portion of it. There are four floors and a basement, but the area of each is not sufficient to make a large whole. When the Rainier Company gave up its building one square above, at Fifty-sixth, the Lozier Company took it. The five floors and basement are so much larger in size that the firm will have plenty of space, for it is more than a factory branch or a selling agency, for it is really the general office and head of the factory and its extended interests.

The general offices of the Lozier Company, with its factory at Plattsburg, will have the entire third floor of the new building, with private offices for the members of the firm and space for the selling and clerical forces. The first and second floors will be set apart for sales and show rooms, with plenty of room for new cars of all models and body style, and at the rear of the first floor will be room for the desks of the retail selling force. The basement will be used as a garage for the demonstrating cars of the company, the fourth floor given over to the second-hand department and the fifth and top floor to the shop and stock room. By the first week of March the renovated building will be occupied, and it is understood that the Buick branch, which is also cramped for space in the same building with the Lozier at present, will consolidate the whole building as its own branch.

Coyote Catching in Colorado with a Stevens-Duryea.

CHASING THE COYOTE WITH AN AUTO.

In all automobiledom there is no more enthusiastic hunter than C. C. Hildebrand, sales manager of the Stevens-Duryea Company, who finds time between selling cars to enjoy his favorite sport. Recently Mr. Hildebrand was in Colorado, and with a party which included Mr. Maxwell, of the Felker Automobile Company, George McGuire, and Mr. Petrie, owner of a pack of grayhounds, drove some 18 miles out of Denver in pursuit of coyotes. In this manner "Hilde" tells the result:

"The first coyote we got within 150 yards of by encircling around it, not driving directly toward it, for this will scare them, and then we opened the tonneau door and let the four dogs out. Then we tried to keep up with the car, at times going 30 miles an hour. To say it was exciting, is putting it mildly. The dogs caught the coyote and stretched him out like a blanket, and we had quite a time breaking them loose. We then waited a few moments to give the coyote a chance to catch his breath, and then turned him loose to have another race, at the same time trying to get a photograph of dogs and coyote on the move. When the picture was developed all it showed was an open prairie and the coyote in the air, his hind legs forward and his front legs between backwards, with no dogs in sight. He pretty nearly got away from us, but we finally caught and skinned him. We caught two more within an hour and a half. The usual method of hunting coyotes is with a horse, so you can imagine how very exciting it is when you are driving in a car at 30 miles an hour over the open prairie, bumping over prairie dog hills and badger holes."

A FAIR DAY'S WORK FOR A FAIR DAY'S PAY.

That a taxicab comes under the rule is a fair assumption, and it is reasonable to consider that a first-class car will do more and better work for the "fare" than will be the outcome if the car is below a certain standard. In England the question is being agitated quite some; the question of the "tariff" considering the quality of the car, in any given case, and S. F. Edge, whose habit of pointedly discussing automobile subjects, takes a hack at the project in the manner, as follows:

1. There should be cheaper fares than at present for single-cylinder cabs and possibly two-cylinders, and the present fares should apply only to four or more cylinder vehicles.
2. Each type of vehicle should be clearly indicated by large figure in front of bonnet, showing number of cylinders.
3. That every taxicab should be painted the same color. I believe post-office red would be the best.
4. That each separate company should be marked with some clear distinguishing mark so that the cabs of the different companies could be identified by would-be fares.

CALIFORNIA AUTOING IN FLOODTIME.

Stockton, Cal., Feb. 15.—The people of California have long been appreciative of the automobile, but not until this Winter have they fully appreciated it as a life boat. Not in forty years has California had such a flood as has been experienced this Winter. In many sections the land was inundated, and the streets of a number of cities and towns were veritable canals. The rise of the water was so rapid that it was often necessary for those in the towns to send automobiles out into the surrounding country to provide a means of escape for the people whose homes were located in outlying districts. Live stock often stood up to the body in the swirling water, a great deal of which was extremely cold; it being the snow from the hills, which had melted and run into the rivers and creeks.

Stockton was probably the city that suffered the most from the flood. With a population of 21,000, it is sixty-three miles northeast of San Francisco, at the head of the Stockton channel, which is a wide and deep arm of the San Joaquin river. The city is termed the "Slough City" on account of the tendency to marshland of the country outside the main portion of town. The business of the section consists chiefly in furnishing supplies to the farmers of the San Joaquin valley, and in the shipment of wheat, wool and mining produce. It also has a number of iron foundries, tanneries and various manufacturers, as it is considered a good harbor, and the steamers are able in the Winter and Spring to navigate 200 miles above the city.

On one side of Stockton is the channel, while a creek flows along the boundary line on the other side. This Winter both streams became so swollen that the river broke through the levees and the creeks overflowed, making the city navigable by little else than boats. It was here that the motor car came to the rescue. Day and night it was used to transfer people and property to higher and dryer quarters.

The accompanying photographs show C. Skinner, of Stockton, in his Mitchell runabout. Mr. Skinner was almost constantly in his car plowing through the water up to the bed of the vehicle in many places. He says his car served faithfully, and did its share toward the alleviation of such suffering as was caused by exposure to the cold and dampness, even in several cases just arriving in time to rescue persons in the greatest danger of drowning. Care had to be exercised, of course, to prevent water from reaching the carbureter or the ignition system. Both were protected somewhat, for the occasion, by use of waterproofing.

Stockton has always, or for sometime passed, felt very favorably toward the motor car and has a goodly number of vehicles in her city, but it is stated that since the experiences of these last few days, the sympathy of everyone is to advance the popularity of the automobile.

Mr. Skinner Rescuing Flood Sufferers in His Mitchell.

NEW ORLEANS RACE MEET SUPPLIES SOME SPORT

NEW ORLEANS, Feb, 22.—Ralph DePalma in his Fiat Cyclone, Mrs. Joan Newton Cuneo in the Knox Giant, and Robert Burman in his underhung special Buick were the star performers in the three days of automobile racing held in this city on Saturday, yesterday, and to-day, upon a one-mile circular track, in connection with the annual Mardi Gras celebration. Records for 10 and 100 miles were broken and fast time made by these three, with George Robertson in a Simplex, Louis Strang in an Isotta, and "Jimmy" Ryall in a Matheson as runners-up.

Although there were few entries for the various events, that drawback was made up in the quality of those who were here and in the time which they recorded. The track was in perfect condition and the attendance was splendid, averaging 10,000 on each of the three days. There was a noticeable lack of accidents, although Ryall was in one serious mix-up, in a short distance event on Sunday, when he steered slightly too wide at the beginning of the turn into the stretch, and, losing control of his big Matheson, flying along at a mile-a-minute rate, crashed through the fence. The car was demolished and it was considered remarkable that Ryall and his mechanic escaped without injuries that were worth mentioning.

The meet opened auspiciously on Saturday, when DePalma lowered the record of 9:12 3-5 for 10 miles, held by Barney Oldfield, to 9:11 2-5, in a handicap race where he defeated five competitors, although he started on scratch with a minute to make up. Ryall was second, 50 seconds behind, and George Robertson third. Mrs. Cuneo then took the center of interest as she flew around the circuit in the big Knox car, and lowered her own five-mile time, the record for women drivers, from 6:04 3-5 to 5:05 2-5. Mrs. Cuneo showed great skill in taking the turns at high speed, and for the first 18 miles of the 50-mile race, the feature of the day, she kept up to the flying Fiat. The 50-mile race was won by DePalma in 51:37 4-5, with Mrs. Cuneo a minute behind, and Robertson third.

On Sunday, Burman made his world record run in the 100-mile free-for-all, lowering the record of 1:53:21 4-5 held by Clemens in a National in 1905, to 1:42:39 2-5. The breaking of this record alone would have drawn great importance to the race meet. The other events of the day were at short distances and relatively unimportant. Mrs. Cuneo lowered the women's one-mile record to 1:00 1-5, better by 2 1-5 seconds than the previous record.

To-day, the last of the speed carnival, was featured by another 50-mile event, which was won by DePalma again, his time being even faster than on Saturday, 49:52 2-5. Mrs. Cuneo drove her Knox five miles in 5:05, a new mark for women drivers. The summaries of the important races are as follows:

Saturday, February 20.

FREE-FOR-ALL, MILE TRIAL FOR WORLD'S RECORD.

1. Fiat Cyclone	De Palma	:54	1-4
2. Matheson	Ryall	1:01	
3. Simplex	Robertson	1:01	3-5
4. Knox-Giant	Mrs. Cuneo	1:02	1-5

50 MILES, FREE FOR ALL.

1. Fiat Cyclone	De Palma	51:37	4-5
2. Knox-Giant	Mrs. Cuneo	52:40	3-5
3. Simplex	Robertson		

10 MILES, FREE FOR ALL.

1. Fiat Cyclone	De Palma	9:11	2-5
2. Simplex	Robertson		
3. Isotta	Strang		

Sunday, February 21.

10 MILES, FREE FOR ALL.

1. Fiat Cyclone	De Palma	10:03	2-5
2. Simplex	Robertson	10:06	
3. Buick	Burman		

10 MILES, OPEN TO ALL STOCK CARS.

1. Knox-Giant	Mrs. Cuneo	10:12	1-5
2. Packard	Donnelly		

100 MILES, OPEN TO STOCK CARS.

1. Buick	Burman	1:42:39	2-5
2. Robertson	Simplex		

Monday, February 22.

5 MILES, FREE FOR ALL, STOCK CARS.

1. Buick	Burman	5:40	
2. Jackson	Schelfler		

5 MILES, FREE FOR ALL, STOCK CARS.

1. Simplex	Robertson	5:07	
2. Buick	Burman		
3. Knox-Giant	Mrs. Cuneo		

5 MILES, STOCK CARS, AMATEUR DRIVERS.

1. Knox-Giant	Mrs. Cuneo	5:15	2-5
2. Packard	Donnelly		
3. Jackson	Schelfler		

10-MILE HANDICAP, FREE FOR ALL.

1. Fiat Cyclone	De Palma	9:12	1-5
2. Knox-Giant	Mrs. Cuneo		
3. Simplex	Robertson		
4. Isotta	Strang		
5. Buick	Burman		

50 MILES, FREE FOR ALL.

1. Fiat Cyclone	De Palma	49:52	2-5
2. Isotta	Strang		
3. Simplex	Robertson		

APPERSON WINS ON PACIFIC COAST.

LOS ANGELES, Feb. 22.—An Apperson Jack Rabbit was the star performer to-day in the Pasadena-Altadena hill climb, one of the most important automobile events held on the Pacific Coast, making the fastest time of the day and defeating Barney Oldfield in his Stearns by five seconds. The mile and four-tenths climb, with a grade averaging 11 per cent., was covered by the winner in 1:24 from a standing start.

ACTIVITIES OF NEW YORK TRADE ASSOCIATION

VARIOUS activities that will have a tendency toward enlivening New York trade circles with something different from the regular business lines, and at the same time be of great benefit to the sales departments of the concerns, are being planned by the New York Automobile Trade Association. A hill climb on the Fort George hill, a week of carnival festivities and a two-day endurance run to the Catskill Mountains.

The hill climb has been scheduled for April 10 and will take the place of the event which had to be postponed from last Fall, with the same rules and regulations in effect, the classification probably to be by price and also by horsepower. June 11 and 12 have been considered as the best dates for a repetition of the successful touring contest of last Fall, when the cars were driven down to Montauk Point and back, giving the members and their friends not only a pleasant tour and a view of the wild and yet beautiful end of the island, but also a touch of real seasickness.

To avoid the necessity of camping out upon a steamer, it has been suggested that Catskill would be a favorable terminus of the first day's run this year, going to the mountains along the west shore of the Hudson and on the second day, leaving in the early morning, crossing over to the eastern shore and thence to the Berkshires, reaching New York City that afternoon or early evening. This would give the cars a strenuous test and the contestants a beautiful trip. President Eveland has appointed Charles P. Skinner, of the Mitchell Motor Car Company, the chairman of a committee to formulate the rules and to plan the itinerary.

At a meeting to be held this afternoon at the offices of the Trade Association the present official garage storage rates for automobiles, and the sale price of gasoline, oil and labor, which have been successfully maintained since October 1, 1906, will be revised to meet present changing conditions. The Pope-Hartford Auto Company has been elected a member of the association.

New Building of Miner Garage Company, Hartford, Conn.

Hartford, Conn.—One of the finest salesrooms and garages in the country for a city of its size is that of the Miner Garage Company, dealers in Pierce-Arrow cars. Instead of being adapted from a structure originally built for some other purpose, this building was constructed primarily for the automobile business. A separate entrance and exit are provided for cars, and at the rear of the sales and display rooms there is an unique feature, an entrance for women who wish to see the cars on the floor Surmounting one corner of the structure is a double, upright electric garage sign. As is characteristic of the buildings of almost all dealers in Pierce-Arrow cars this one has a look of permanency and of being especially fitted for the purpose for which it is employed.

Baltimore, Md.—A two-story garage, the design of which will represent an old English inn, is to be erected at the southwest corner of North Avenue and Lovegrove Alley for the Auto Outing Company, of which George W. Eisenhauer is president. The lot has a front of 39 feet on North Avenue and extends back 175 feet. Reinforced concrete will be the material used for the construction of the garage. The company has just recently closed negotiations for the agencies of the Palmer-Singer, Simplex and other cars.

Bridgeport, Conn.—The Aston Motor Car Company, formerly of 1185 State street, has recently taken possession of its new concrete garage at 1125 State street. The new quarters are 100 feet in depth, with 60 feet frontage, furnishing floor space for about 40 cars. In the rear is an up-to-date machine shop, where a few cars are assembled for local patronage.

Waterbury, Conn.—The Rambler garage, of which H. M. Turrell is manager, expects to take possession on April 1 of a new garage and repair shop located just above the present quarters at 17 Jefferson street. The new building will be of brick, two stories in height, 50 feet across the front and 100 feet deep.

Lambertville, N. J.—A full line of accessories will be carried by O. A. Burd & Son, who will also handle the American Mors car. This concern has opened one of the largest and best equipped garages in the State of New Jersey. The repair shop is in the hands of competent mechanics.

Raleigh, N. C.—F. H. Brewer, Franklin dealer, has formed the Carolina Garage & Machine Company, which is erecting a two-story building. It is intended to make the structure one of the best equipped garage buildings in the South. The entire lower floor will be used as a showroom.

Philadelphia.—The newest garage in the city has been opened by Frederick K. Mears at 4525-4527 Springfield avenue, where he has moved from Regent street, near Forty-seventh, retaining the trade name of the Regent Garage. A large elevator gives access to upper floors.

Scranton, Pa.—The Standard Motor Car Company's new garage building in Forrest and Dupont courts has been started, ground having been broken.

South Bend, Ind.—The Otis Motor Car Company, Franklin dealers, will build a garage and salesroom, 20 by 80, in the heart of the business district.

Detroit.—W. G. Isbell has sold his garage at 730-732 Woodward avenue, but will retain the American Simplex agency quarters in the same block, at No. 742.

Nashville, Tenn.—The Tennessee Automobile Company, located at Twelfth avenue and Broadway, has opened one of the largest and most complete garages in the South.

Detroit.—J. P. Schneider's new garage building at Woodward avenue and Bagg street is complete, and will be occupied immediately, the old building on Jefferson avenue being vacated.

Cleveland.—A two-story garage will be erected facing East Sixty-sixth street for the Babcock Electric Company, of Buffalo, N. Y. This will be a fireproof structure, to cost $40,000.

El Paso, Texas.—The new building at 324 Texas street, in the heart of the city, has been occupied by the P. L. Abel Cycle Company. This company handles the Franklin, and in the new place will have a floor space 30 by 125 feet.

Cumberland, Md.—The Windsor Garage Company has been incorporated under the laws of Maryland; capital, $5,000. Directors are J. C. Powell, F. E. Perrin and W. O. Cole, all of Cumberland. The company is erecting a garage and will do repairing.

Detroit.—A recently organized firm, composed of A. J. Mandel, A. G. Zeller and C. Zeller, will do a general storage and repair business, as well as dealing in second-hand autos, at 10 Selden avenue, under the name of the Economy Auto Garage.

Charlotte, N. C.—The large garage now being built by Osmond L. Barringer on Eighth street will be a noteworthy addition to the automobile facilities of this section. This is 50 by 180 feet in size, and the building will be strictly up to date.

New York City.—A newcomer in the taxicab ranks is the Parkway Garage Company, of Central Park West and 110th street, with the Royal Blue Service. This is so called because the cars used, of the Thomas make, are finished in a beautiful blue color known as Royal blue. This was a special finish, which the company designated in purchasing the car, the upholstering being carried out to match. This service, for which the usual metropolitan rates obtain, will be conducted from the company's garage at the above address, at which place cabs are always kept ready and in waiting. Located, as it is, up in the fashionable district, a good business should result. For new users of cabs the company gives the following protective advice, observe: (a) That the flag on the taximeter is lowered at the beginning of the service and not before: (b) that the flag is maintained in that position during the service; (c) that the flag is properly brought to "payment" position at the conclusion of the service.

Parkway Garage, at 110th Street, New York City.

One of Washington's Old Headquarters.

S. H. Hansbrough, President of the Shenandoah National Bank, Winchester, Va., with wife, daughter and son, in front of General Washington's old headquarters, occupied in 1755 by the Father of His Country, and one of the many historical spots in that section of the country. Mr. Hansbrough is an enthusiastic Rambler owner.

"Magneto" Sims on Six-cylinders.—Frederick G. Sims, of London, a pioneer automobile builder and well known in this country as the maker of the Sims-Bosch magneto, was a recent visitor at the Winton plant in Cleveland. Mr. Sims has organized an airship exhibition to be held at Olympia in March. Among the exhibits will be his own airship, propelled by a six-cylinder gasoline motor. "The British automobile trade is not as active as could be desired," said Mr. Sims. "Among the makers of big cars about the only ones who are keeping busy are the six-cylinder manufacturers. British people who have the means to get good cars find the six the only type worth buying. I am a six-cylinder enthusiast myself and look to see six motors in almost universal use, in little cars as well as big ones."

Receiver's Report Shows Big Cash Balance.—The report of Henry W. Nuckols and Halsey M. Barrett, receivers of the Electric Vehicle Company, Hartford, Conn., for the month of January has been duly filed with the Superior Court. Cash sales are noted as being $25,713.72 and purchases amount to $31,095.85. Cash was collected on the receiver's account to the amount of $25,354.15, while from the Selden patent royalties was realized the sum of $101,206.68. Under the head of disbursements the A. L. A. M. is credited with having been paid $40,701.71 by the receivers. The cash balance foots up $173,936.45.

Hartford Parts Company Moves to Larger Quarters.—So great has been the demand for its universal joints that the Hartford Auto Parts Company has found it necessary to move to larger quarters. The company has leased the west wing of the Colt's patent firearms factory, at No. 80 Huyshope avenue, and is now busily engaged in moving to this new location. The latter will give the company four times as much space as formerly occupied. Thus the new building will allow the installation of such additional machinery as the rapidly increasing business has made necessary.

A Firm That Did Not Overcharge.—The Winkley Company of Detroit, manufacturers of oiling devices, is showing with pardonable pride a letter received from D. W. Carter, assistant secretary of the State Mutual Life Assurance Company, of Worcester, Mass., in regard to the price of a certain small device which the Detroit firm sold for eight cents. Mr. Carter writes in part: "It is a pleasure to find a concern which does not impose on the autoist. A local dealer wanted a dollar for the same thing."

Large Commercial Car Shipment.—Four carloads of commercial cars in one shipment from the factory in Buffalo of the Auto-Car Manufacturing Company is considered by the officials to be one of the largest shipments of its kind on record. A number of the machines were three-ton, six-cylinder, 60-horsepower cars, all being sent to the Boston agents, Abbott & Miller. F. C. Lindoerfer, the general sales manager, has returned to the factory from an extended Eastern trip.

Billings & Spencer Company Election.—At the annual meeting of the Billings & Spencer Company, held in Hartford, Conn., recently, the following board of directors was re-elected: C. E. Billings, F. C. Billings, C. M. Spencer, L. H. Holt, Silas Chapman, Jr., E. H. Stocker and L. D. Parker. At a subsequent meeting of the board of directors the following officers were re-elected: President and general manager, C. E. Billings; vice-president and superintendent, F. C. Billings; treasurer, L. H. Holt.

OBITUARY.

Russell Drisko, one of the best known men in the automobile trade in Boston, died on Thursday of last week at his home in that city. Mr. Drisko at one time handled the Mors in Boston, and after that was connected with the late F. F. Randall in the sale of Stevens-Duryeas. More recently he had the management of the Boston store of the Bay State Forty, and later on was for a short time in charge of the Grout factory at Orange, Mass. After leaving there he had charge of the Boston branch of the Jones Speedometer Co.

BOSTON TRADE CHANGES.

BOSTON, Feb. 20.—Two interesting trade changes were announced to-day. One of these is the placing of the Stearns agency, formerly held in Boston by Morgan B. Kent, with J. H. MacAlman, the Columbia agent and president of the Boston Dealers' Association. Mr. MacAlman will continue also as agent for the Columbia, but he has taken additional quarters at No. 889 Boylston street. There his salesroom will be located, but he will retain his garage and repair shop on Stanhope street. Mr. MacAlman is one of the veterans in the trade, dating back twelve years. He was manager of the Locomobile branch up to a few years ago, when he took charge of the Electric Vehicle Company's branch. Since that branch was discontinued he has sold Columbia cars.

The other new agency is for the Mora, which is to be handled here by the G. H. Proctor Supply Company, at No. 25 Irving street.

IN AND ABOUT THE AGENCIES.

Fiat, Philadelphia.—Louis J. Bergdoll has taken over the agency for this city and surrounding territory of the Fiat cars, thus displacing the former branch of the Fiat Automobile Company. The branch has really been moved to Chicago to take charge of the interests there, and with a well established trade in the Quaker City was hardly needed according to the policies of the importers. Mr. Bergdoll will personally manage the sales of these cars at the corner of Broad and Vine Streets, in one of his new buildings. At present the American Locomotive, Oakland and Rauch & Lang are also sold there.

Stevens-Duryea, Philadelphia. — Besides their new garage and salesrooms at Nos. 202-204 North Broad street, A. G. Spalding & Bros., Philadelphia agents of the Stevens-Duryea, will hereafter use the concern's general sporting goods store at No. 1210 Chestnut street as an additional salesroom. J. F. Grey is in charge of the latter, while F. W. Eveland will manage the Broad street establishment.

Continental Opens Chicago Branch.—On account of a large amount of business which is handled in Chicago, the Continental Caoutchouc Company of New York has opened a branch in that city. This is the third branch established, the others being in San Francisco and Detroit, the general sales trade of the country being handled by distributing agents.

Lozier's New Broadway Location.

Atwood-Castle Stand at Chicago Show.

First Foreigner in Baltimore.—The first foreign car to be exhibited at any show in Baltimore is the Renault. The Stoddard-Dayton Baltimore Auto Company, Leo Shaab, manager, has just closed a deal for the agency. This is also the first and only foreign car that has ever had an agency in that city.

Welch, New York City.—An agency for the Welch cars will be opened in this city by Welch & Forrester, who will take possession of the salesroom on Broadway, near Sixty-third Street. A. R. Welch, who is at present the manager of the Welch Motor Car Company, is to be of the firm.

Palmer-Singer, Philadelphia. — From now on the Palmer & Singer Company's line will be represented in Philadelphia, the agency having been secured by William and Charles Miller, at No. 441 N. Broad Street.

Stewart & Clark, Detroit.—A branch office has been opened at No. 697 Woodward avenue, where the Detroit trade will be handled in the future. This office will be in charge of C. E. Brelsford.

E. M. F., New Ulm, Minn.—The Albrecht Motor Car Company has been organized to operate a large garage and to handle the E. M. F. 30 in the local territory.

PERSONAL TRADE MENTION.

J. L. Sternberg has severed his connection with the Everett-Metzger-Flanders Company and has gone into the retail business at 119 East Second street, Wichita, Kan., with a branch store at Enid, Okla. Mr. Sternberg was for several years with the Northern Motor Car Company of Detroit, and in his new enterprise will be associated with M. L. Arnold and C. S. McClellan, of Enid, Okla., who have already taken on the agency of the Inter-State car, made at Muncie, Ind., and expect to close for other agencies in the near future. The concern will operate under the name of J. L. Sternberg & Co. at both Wichita and Enid.

C. E. Brelsford, for several years past Detroit manager for the Witherbee Igniter Company, has resigned and accepted a position with the Stewart & Clark Mfg. Company as Detroit manager, and will locate on Jefferson avenue in the near future, exact location to be announced later.

Charles C. Craig, long identified with the automobile trade and well known all over the United States, has been engaged by the Haynes Automobile Company as special traveling representative, and will cover the Western territory in the interests of the Haynes Company.

C. Klug, who has been connected with the main office of the Witherbee Igniter Company of New York for some years past, has been appointed manager of the Detroit branch, vice C. E. Brelsford, resigned. Mr. Klug is now at headquarters at 220 Jefferson avenue, Detroit.

Fred. G. Browning, for many years prominently identified with the factory and the Autocar Company's business at Ardmore, Pa., has been transferred to the management of the company's Philadelphia branch at 249 North Broad street.

Alexander Winton, president of the Winton Motor Carriage Company, accompanied by Mrs. Winton, sailed from New York on the Lusitania February 15 for a six weeks' visit to England and Scotland.

Louis Mansbach, for many years of the firm of Isaac Mansbach & Company, of Philadelphia, is now connected with the sales forces of the German Benz car, at the Benz headquarters in New York City.

Harry T. Clinton, until recently the manager of the branch of the Fiat Automobile Company in Philadelphia, has moved his headquarters to Chicago, where he will have charge of the Fiat branch there.

Ezra Kirk, one of the well-known figures in the automobile industry, has taken the Western sales managership for the Herreshoff car, manufactured and marketed by the Harry S. Houpt Company.

How Michelins Were Shown at Chicago.

Evans Church has been appointed manager of the Philadelphia branch of the Eastern selling district of the White Company, taking the place of Max Greene.

WAIL OF THE SALESMAN.

Everybody works but the factory
They sit around all day;
Always writing letters—
"Expect to ship," they say.

Customers keep on calling—
New stories we must tell;
Everybody works at the factory,
Yes they do, like ——!

E. T. B.

LEAR RECEIVER TEMPORARY.

SPRINGFIELD, O., Feb. 22.—In order to be better able to increase its capital, and as a temporary measure, the Oscar Lear Automobile Company, manufacturer of Frayer-Miller automobiles, has had a received appointed to take charge of the business affairs of the concern. Realizing that more capital was necessary in order to carry on the business on more progressive lines than before, this step was determined upon. The application states that the assets of the company are $308,000 and the liabilities are $144,140. The capital stock is $300,000. The receiver appointed is highly satisfactory to the officers and stockholders of the company, and it is predicted that within a short time the concern will be in a better position than at any previous time.

Four White Steam Taxicabs Purchased by Matt De Freest, One of the Largest Liverymen in Albany, N. Y.

VOL. XX NEW YORK—THURSDAY, MARCH 4, 1909—CHICAGO No. 9

THE AUTOMOBILE

BOSTON, March 4.—Boston's automobile show, the last of the series of exhibitions of national consequence, the snapper of the whip that brings the buying public into line and sends them scurrying off for the last lap of the race for the new models, will open next Saturday evening in Mechanics Building, the great structure on Huntington avenue that has been the scene of so many successful automobile shows in the past. This is the seventh annual show conducted by the Boston Automobile Dealers' Association under the management of Chester I. Campbell, and there is every indication that it will exceed its predecessors in size and in results. Practically every inch of space has been sold to exhibitors of motor vehicles, or the things that go with them, and that means that the show will be the largest of its kind in the country. Year after year it has been necessary, in order to keep step with the growth of the industry, to gain more space. First, the show spread to every part of the building, then the motor boats were crowded out, and this year, in order to satisfy the demands of prospective exhibitors, Manager Campbell has been obliged to dispossess the restaurant and instead of a feast for the inner man there will be provided in Talbot Hall a feast for the eyes, in the form of new automobiles.

It is to the Boston show that all Yankee land looks for the latest ideas in automobiles. Some Bostonians, and a few of the dealers in the smaller cities, go over to the national shows in New York; the smaller shows, such as those in Hartford, Portland, and other places satisfy a certain local need, but the New Englanders who are really interested in the automobile and its accessories flock to the Boston show, for they know from experience that they will find there practically everything that has been exhibited elsewhere, and usually a number of novelties which first make their appearance in Boston. At this show, as in Chicago, there are no distinctions of licensed or unlicensed, or previous condition of nationality, and all machines are exhibited here on an equal basis. Thus the visitor has the only opportunity in this part of the country to see domestic and foreign, licensed, unlicensed and independents together.

The Boston show is par excellence a retail exposition. It is not intended as a place for the meeting of manufacturers and agents, for by the middle of March practically all the agencies and sub-agencies have been placed. Nevertheless, there is usually some business of this sort transacted. Primarily, however, the Boston show is a place where the local dealers and the manufacturers rub elbows with the owners and owners-to-be, and sales are made just as in the salesrooms. Of perhaps more importance than the actual sales is the interest which the show creates just before the opening of the riding season. This is just the right time for a retail show, and the Boston dealers believe that their exhibition does more good to the trade by the stimulation of interest among the public than in any other way.

There are more than four hundred exhibitors this year in the Boston show, a larger number than at any previous exhibition. For show purposes the exhibition space in the great building has been divided into eight departments. Department A includes the main floor of the grand hall, devoted exclusively to the exhibits of pleasure cars, with a few for the trade and daily publications interested in motoring. Department B is the main floor of exhibition hall, adjoining the grand hall, and this also is set aside exclusively for pleasure vehicles. Department C is the basement under the grand hall and in this section most of the com-

mercial vehicles will be shown, though there will be some exhibits of sundries and of cars for which no space could he found on the upper floors. Department D is the basement under the exhibition hall with motor cycles and their sundries. Department E is in the first balcony of the grand hall, and it is in this part of the building that many of the tire manufacturers have secured spaces, as well as manufacturers of lamps and other accessories. Departments F and G are also devoted to the exhibition of accessories, while Talbot Hall is to be used for an overflow exhibition of automobiles. Departments F, G and Talbot Hall are on the upper floor over Exhibition Hall.

The Boston Automobile Dealers' Association long ago took the initiative in the uniform decoration of Mechanics Building, on the occasion of the automobile show, and it has made some notable successes in the way of decorations. The New England apple orchard of a few years ago and the more recent Italian garden are well remembered. For this year Manager Campbell has departed somewhat from his former practise in that the show building will represent an interior rather than an out-door scene. For months the decorators have been at work preparing the mass of materials that make up the decorations, and since the first of this week hundreds of men have been busily engaged putting in place the setting for the 1909 crop of automobiles. That the decorative effect will be fully up to the standard of Boston shows is the promise of the management.

Exhibition Hall, as it is being arranged, has been appropriately termed the "hall of arches." Over all the aisles there are being put in place great arches which will be illuminated with thousands of electric lights. Nearly one hundred arches are to be used in this hall. The great posts which support the upper floor of Exhibition Hall have been entirely concealed and made into artistic pillars with bases of green onyx marble. At the top of the marble pillars have been placed ivorized plaster capitals, and from these spring the arches which span the aisles and extend longitudinally down the sides. The arches are highly decorative with corner beads of raised plastic ornaments. At the crowns of the arches are placed escutcheons and the wide soffits or undersides of the arches are to be studded with incandescent electric lamps, each set in a decorative rosette. The square ceilings produced by the arrangement of the arches are being covered with sunbursts of materials in colors harmonizing with the general decorative scheme. In the center of each sunburst depends an electric chandelier, which, with the incandescent lamps, makes the archway exceedingly brilliant. The side walls and detached posts in Exhibition Hall have been covered with material in old gold and green, harmonizing well with the rest of the decorations. Panelling of gold moulding on the side walls adds to the effectiveness of the general scene. The stairways leading to the upper floor from Exhibition Hall are covered with the green onyx material to resemble onyx marble stairways. On the flooring of the exhibition spaces is laid a green covering.

In Grand Hall the piece de resistance of the decorative scheme is the stage. This immense span, with its great proscenium arch, is a difficult proposition for the decorator, but in this instance the treatment has been extremely successful. On either side of the stage great pilasters of plaster have been erected. These are modelled in the form of decorative panels with green onyx and ivorized plaster bases. Upon each panel in high relief is a modelled female figure representing the "genus of progress." Each figure holds aloft in both hands flaming torches in which cunningly concealed electric lights flash out as the torches revolve. Immediately above the heads of the genii are placed the numerals, "1909," set out in incandescent lamps. A specially designed and painted curtain is draped from the top of the proscenium arch and this hangs in graceful folds covering not only the top of the stage but the sides beyond the pilasters and making a very pleasing effect. In connection with this curtain electric lamps are used in profusion, great cables of them extending along the edge of the folds and a fringe depending from the edges. Several thousand incandescent bulbs are used in this work alone. The top of the stage has been covered. The side stairways and the central approach to the stage are treated in green onyx and the stage front is covered.

The band stand is located in the center of the Grand Hall, and is raised to the balcony level. It has a decorative canopy above and is surrounded by a scroll work railing. The balcony fronts have been covered with an ivory shaded background, over which has been draped green foliage and flower decorations, entwined with veri-colored electric lamps. The great beams which support the roof have been concealed and here electricity is used with great extravagance for purposes of illumination and decoration. To divide the exhibition spaces a special fence has been designed, consisting of a wooden scroll of pierced work with varnished railings. At the aisle ends of each dividing fence are artistic corner posts, from which rise the standards supporting the signs. The signs this year are a novelty and quite different from anything used in other shows. They consist of wrought iron standards artistically fashioned, with an oval frame at the top, in which is placed the sign of the exhibitor. The background of the sign is green onyx and the letters are black and edged with gold. The signs are exceedingly neat, and the abandonment of the old-fashioned long sign adds to the commodious effect of the hall. There are no arches in the Grand Hall, so there is nothing to interrupt the view. At the same time the spaces are divided so that there will be no confusion.

In the basement less elaborate decorations are possible than on the floor above, for decorations that are too heavy interfere with the exhibitors. Nevertheless, the basement has been suitably decorated, the bare sidewalls and posts being hidden, and just enough decoration given the ceiling to conceal the beams. The decorative scheme in the basement harmonizes with that of the main floors, the general color scheme being green and ivory. In the balconies the same signs and dividing fences are used as on the main floor.

In speaking of the decorative scheme for the show, taken in its entirety, Manager Campbell says: "We have always taken especial pride in setting the pace for other shows all over the country in this particular respect, and one can always find the influence of our decorations in subsequent exhibitions in other cities. It has become a fact that the public has become so accustomed to having its annual feasts of automobiles in attractive, original and really magnificent settings that the standard must necessarily be one not only of general beauty, but of architectural excellence.

"We studied for a considerable time as to how we could so change the appearance of the halls here to make them better than anything ever seen here before, and we feel that, to a large degree, we have been successful, so that it is without trepidation that we will throw open the doors. The cars for exhibition purposes have been arriving steadily for several days, some having come direct from Chicago, and we also expect that when the public is admitted to the show that it will be a complete one."

THE LIST OF EXHIBITORS

CARS FOR PLEASURE AND COMMERCIAL USES.

Acme—Boston Motor Co., 43 Columbus ave.
A-K—Allen-Kingston Motor Car Co., 387 Boylston st.
American—American Auto Co., 16 Columbus ave.
Apperson—Fred. S. Smith, 38 Columbus ave.
Atlas—South End Motor Car Co., 24 E. Concord st.
Austin—Austin Automobile Co., Grand Rapids, Mich.
Autocar—Fred. S. Smith, 38 Columbus ave.
Autocar Trucks—Autocar Equipment Co., Buffalo, N. Y.
Bailey—S. R. Bailey & Co., Amesbury, Mass.
Baker—A. F. Neale, 10 Columbus ave.
Berliet—Park Square Auto Station, Park sq.
Brush—South End Motor Car Co., 24 E. Concord st.
Buick—Buick Motor Co., Park sq.
Cadillac—Alvin T. Fuller, Park sq.
Chadwick—Curtis-Hawkins Co., 218 Eliot st.
Chalmers-Detroit—Whitten-Gilmore Co., 907 Boylston st.
Chase—Chase Motor Truck Co., Syracuse, N. Y.
Columbia—J. H. MacAlman, 74 Stanhope st.
Columbus—Algonquin Motor Car Co., 97 Massachusetts ave.
DeLuxe—Kissel Kar Kompany, 741 Boylston st.
Detroit—Anderson Carriage Co., Detroit, Mich.
EMF—Studebaker Brothers of New York, 1020 Boylston st.
Fiat—Fiat Automobile Co., New York City.
Ford—Ford Motor Co., 147 Columbus ave.
Franklin—Franklin Automobile Co., 671 Boylston st.
Frayer-Miller—D. P. Nichols & Co., 116 W. Brookline st.
General Trucks—General Vehicle Co., 84 State st.
Glide—Crown Motor Car Co., Park sq.
Gramm-Logan—Gramm-Logan Motor Car Co., Bowling Green, O.
Grout—Henry F. Farrow, 94 Massachusetts ave.
Gyroscope—George H. Lowe, 11 Park sq.
Holsman—General Auto Co., 10 Columbus ave.
Hotchkiss—Hotchkiss Import Co., New York City.
Hupmobile—Hupmobile Motor Car Co., Detroit, Mich.
Inter-State—S. M. Supply Co., 22 Lincoln st.
Jackson—Jackson Automobile Co., Jackson, Mich.
Jewel—Jewel Motor Car Co., Massillon, O.
KisselKar—Kissel Kar Kompany, 741 Boylston st.
Knox—Reed-Underhill Co., 222 Columbus ave.
Lambert—Chas. A. Eaton, 64 Pembroke st.
Lancia—Hol-Tan Co., 66 Hereford st.
Locomobile—Locomobile Co. of America, 400 Newbury st.
Marmon—F. E. Wing, 12 Columbus ave.
Matheson—Matheson Auto Co., New York City.
Maxwell—Maxwell-Briscoe-Boston Co., 121 Massachusetts ave.
McCue—McCue Co., Hartford, Conn.
Mitchell—W. M. Jenkins & Co., 286 Columbus ave.
Mora—Mora Motor Car Co., Newark, N. Y.
Napier—Napier Motor Co. of America, Jamaica Plains, Mass.
National—Linscott Motor Co., 163 Columbus ave.
Oakland—Oakland Motor Car Co., Buffalo, N. Y.
Oldsmobile—Algonquin Motor Car Co., 97 Massachusetts ave.
Overland—Linscott Motor Co., 163 Columbus ave.
Packard—Alvin T. Fuller, Park sq.
Palmer-Singer—Palmer & Singer, 1620 Broadway, New York.
Panhard—Panhard & Levassor, 901 Boylston st.
Peerless—Peerless Motor Co., 174 Columbus ave.
Pennsylvania—George H. Lowe, 11 Park sq.
Pierce-Arrow—J. W. Maguire Co., 754 Boylston st.
Pittsburg—Stanley Webster Co., 1024 Boylston st.
Pittsburg Six—Fort Pitt Motor Mfg. Co., New Kensington, P.
Pixley—G. H. Pixley Co., 239 Columbus ave.
Pope Hartford—Dodge Motor Vehicle Co., 25 Irvington st.
Pope Waverley—Dodge Motor Vehicle Co., 25 Irvington st.
Premier—Premier Boston Depot, 1008 Boylston st.
Pullman—York Motor Car Co., York, Pa.
Rambler—Thomas B. Jeffery & Co., 73 Massachusetts ave.
Rapid—Butler Motor Car Co., 12 Harcourt st.
Regal—George H. Lowe, 11 Park sq.
Reo—Linscott Motor Co., 163 Columbus ave.
Royal Tourist—George J. Dunham, 182 Columbus ave.
Sampson—Alden Sampson Mfg. Co., Pittsfield, Mass.
Schacht—Schacht Mfg. Co., Cincinnati, O.
Simplex—Palmer & Singer, New York City.
Simplex (American)—American Simplex Co., Boston, Mass
Speedwell—Curtis-Hawkins Co., 218 Eliot st.
Stanley—Stanley Motor Carriage Co., Newton, Mass.
Stearns—J. H. MacAlman, 74 Stanhope st.
Stevens-Duryea—J. W. Bowman & Co., 911 Boylston st.
Stoddard-Dayton—Park Square Auto Station, Park sq.
Studebaker—Studebaker Brothers, 1020 Boylston st.
Thomas—Whitten-Gilmore Co., 907 Boylston st.
Welch—Welch Motor Car Co., 733 Boylston st.
White—White Co., 320 Newbury st.
Winton—Winton Motor Carriage Co., 148 Berkeley st.

MOTORCYCLES.

Crouch—Crouch Motor Co., Stoneham, Mass.
Curtiss—G. H. Curtiss Mfg. Co., Hammondsport, N. Y.
Excelsior—Excelsior Supply Co., Chicago.
F. N.—Ovington Motor Co., New York City.
Greyhound—Auto-Bi Co., Buffalo, N. Y.
Harley-Davidson—Harley-Davidson Motor Co., Milwaukee, Wis.
Indian—Hendee Mfg. Co., Springfield, Mass.
Merkel-Light—Merkel-Light Motor Co., Pottstown, Pa.
Midget Bi-Car—Walton Motor Co., Lynbrook, N. Y.
M. M.—American Motor Car Co., Brockton, Mass.
New Era—New Era Gas Engine Co., Dayton, O.
N. S. U.—N. S. U. Motor Co., New York City.
Pierce—Pierce Cycle Co., Buffalo, N. Y.
Reliance—Reliance Motor Cycle Co., Owego, N. Y.
R-S—Reading Standard Co., Reading, Pa.
Thor—Aurora Automatic Machinery Co., Aurora, Ill
Yale—Consolidated Mfg. Co., Toledo, O.

MAGNETOS AND TIMERS.

Atwater-Kent Mfg. Co., Philadelphia.
Champion Ignition Co., Flint, Mich.
Heinze Electric Co., Lowell, Mass.
Hoyt Electrical Instrument Co., Penacook, N. H.
K. W. Ignition Co., Cleveland.
Lavalette & Co., New York City.
Leland & Co., W. H., Worcester, Mass.
Monitor Mfg. Co., 6 Pelham st.
Pittsfield Spark Coil Co., Dalton, Mass.
Splitdorf, C. F., New York City.
Witherbee Igniter Co., New York City.

TIRES.

Ajax-Grieb Rubber Co., 15 Park sq.
Atlas Rubber Co., Buffalo, N. Y.
Batavia Rubber Co., Batavia, N. Y.
B. F. Goodrich Co., Akron, O.
Boston Tire & Rubber Co., 184 Friend st.
Commonwealth Rubber Co., Reading, Mass.
Continental Caoutchouc Co., New York City.
Diamond Rubber Co., Akron, O.
Dow Tire Co., New York City.
Empire Auto Tire Co., Trenton, N. J.
Firestone Tire & Rubber Co., Akron, O.
Fisk Rubber Co., Chicopee Falls, Mass.
Goodyear Tire Co., Akron, O.
G & J Tire Co., Indianapolis, Ind.
Hartford Rubber Works Co., Hartford, Conn.
Michelin Tire Co., Milltown, N. J.
Morgan & Wright, Detroit, Mich.
Pennsylvania Rubber Co., Jeanette, Pa.
Republic Rubber Co., Youngstown, O.
Rutherford Rubber Co., Rutherford, N. J.
Shawmut Tire Co., 97 Bedford st.
Swinehart Clincher Tire Co., Akron, O.

TIRE ACCESSORIES.

Auto Tire Inflating Co., Brooklyn, N. Y.
Hopewell Bros., 42 Osborne st.
Leather Tire Goods Co., Newton Upper Falls, Mass.
Teel Mfg. Co., Medford, Mass.
Voorhees Rubber Mfg. Co., Jersey City, N. J.
Zegisn Bullet Proof Cloth Co., Chicago.

BATTERIES.

American Storage Battery Co., 8 Congress st.
Burn Battery Co., Boston, Mass.
Eastern Carbon Works, Jersey City, N. J.
Electric Storage Battery Co., Philadelphia.
National Carbon Co., Cleveland, O.
Vesta Accumulator Co., Chicago.
Witherbee Igniter Co., New York City.

COILS AND GENERAL IGNITION.

Champion Ignition Co., Flint, Mich.
Heinze Electric Co., Lowell, Mass.
Hoyt Electrical Instrument Co., Penacook, N. H.
Leland & Co., W. H., Worcester, Mass.
Pettingell-Andrews Co., Pearl st and Atlantic ave.
Pittsfield Spark Coil Co., Dalton, Mass.
Spiltdorf, C. F., New York City.

LUBRICANTS AND LUBRICATORS.

Columbia Lubricants Co., New York City.
Dixon Crucible Co., John Hancock Building.
Eagle Oil & Supply Co., 104 Broad st.
Harris Oil Co., Providence, R. I.
Havoline Oil Co., 749 Boylston st.
Hawa, George A., New York City.
Kellom & Co., Philadelphia.
Keystone Lubricating Co., Philadelphia.
N. Y. & N. J. Lubricants Co., New York City.
Randall-Faichney Co., Causeway st.
Robinson & Son Co., Wm. C., 44 Commercial st.
Underhay Oil Co., 77 Batterymarch st.
Vacuum Oil Co., Rochester, N. Y.
White & Bagley Co., Worceeter, Mass.
Young & Kimball, 111 Purchase st.

SHOCK ABSORBERS AND RUNNING GEAR.

American Stepney Spare Wheel Co., New York City.
Fientje, Ernest, Cambridge, Mass.
Gabriel Horn Mfg. Co., Cleveland.
Hartford Suspension Co., Jersey City, N. J.
Kilgore Mfg. Co., 585 Boylston st.
Sager Co., J. H., Rocheeter, N. Y.
Whitney Mfg. Co., Hartford, Conn.

SPEEDOMETERS.

Auto Improvement Co., 319 Columbus ave.
Hoffecker Co., 222 Eliot st.
Jones Speedometer Co., New York City.
Jones, Wm. Herbert, 147 Columbus ave.
Loring Auto Appliance Co., New York City.
Parker Mfg. Co., Roxbury, Mass.
Veeder Mfg. Co., Hartford, Conn.
Warner Instrument Co., 925 Boylston st.

PUMPS, MUFFLERS AND HORNS.

Compressed Air Power Co., 35 Congress et.
Gabriel Horn Mfg. Co., Cleveland.
Nightingale Whistle Mfg. Co., New York City.
Randall-Faichney Co., Causeway st.

MATERIALS.

Cramp Ship & Engine Co., Philadelphia.

Travelers' Insurance Co., Hartford, Conn.
Twin Elm Spring Co., Lexington, Mass.
Walker Lithographing Co., 221 High st.
Ward & Sons, Edgar T., 23 Purchase st.
Winestock Mfg. Co., Perkinsville, Vt.

ENDURANCE RUN FROM NEW YORK TO BOSTON SHOW

THAT New York automobile circles welcome a chance for a run to Boston has been shown by the fact that, to date, there are twelve entries promised by tradesmen and private owners to Mills & Moores, who have been given charge of the first spring endurance contest. The Chester I. Campbell trophy has been donated by L. H. Perlman, the New York Welch agent, who is the present holder of it, with the suggestion that it be put up for annual competition, to be won twice to be retained. Two Franklin cars, two Loziers, and one each of the following have been listed: Haynes, Stearns, Renault, Zust, Mora, White, Thomas and Acme. It is confidently expected that many more than this will start from Columbus Circle on next Thursday morning, March 11. R. H. Johnston of the White Company, will precede the contestants and pilot them from Worcester into Boston, while members of the various local clubs will show the way through New Haven, Hartford, and Worcester. The cars will run on a twenty mile an hour schedule, and will be required to check at a number of places en route.

NEW ENGLAND A UTOPIA FOR THE AUTOIST

BOSTON, March 4.—No section of the country possesses so much wealth in proportion to area as New England; no group of six States has such good roads, and in few parts of the world can the traveler enjoy such a variety of scenery in comparatively a short journey. It is no wonder, therefore, that this northeast corner of the nation attracts motorists from far and wide, and that its people were first to take up the automobile.

Primarily New England is not an automobile manufacturing center; there are a few factories and they produce some of the best cars, but the main interest of New England in automobiles is as a consumer rather than a producer. In Massachusetts alone there are some 18,000 cars. Probably in the other five States there are at least as many more, and during the Summer months thousands of machines from every part of the union use the New England roads. The White Mountains, the Maine coast, the Berkshires and Cape Cod are accustomed to the registration tags of Illinois and Indiana, of Pennsylvania and of New Jersey and other places more remote. Over the main thoroughfares there is a tremendous traffic of pneumatic-tired vehicles. That New England appreciates the value of autoing cannot be denied and that it is trying to make things pleasant for the motorist also is true. Massachusetts was one of the very first States to adopt a motor vehicle law, and it was upon the statute of 1903 that many of the laws passed in other States have been based, though some of the copies have been far less lenient toward the motorist than the original. And from year to year, often at the request of the autoists themselves, the law has been changed until it is regarded as one of the fairest statutes of the kind in existence. Some of the other States have gone further than Massachusetts. Connecticut has a new law, and in some respects a better one; Rhode Island has a more liberal speed limit, and the laws of New Hampshire and Maine excel in some points. But taken as a whole, the New England States have been fair to motorists in the past in the matter of laws. Now they are considering a further step in the adoption of a uniform law. Such a law has been drafted and is before the law-making bodies in several States. If it is generally adopted, New England will set the rest of the country another example and tourists by motor car will appreciate the advantage of being able to travel from one State into another without being under the necessity of familiarizing themselves with a new code of laws and rules every time a boundary line is crossed.

But New England is doing much more for the automobilist than providing fair and uniform laws; it is giving him what is far more important, the best roads in America. Here again Massachusetts leads. The old Bay State has something like 700 miles of scientifically built, smooth macadam highways stretching from one end to the other of the commonwealth and connecting all the important centers of population. And this Spring, when one little stretch of State highway near the famous Jacob's Ladder, in the Berkshires, is finished, a motorist may enter Massachusetts at its westerly end and may travel its whole length to Boston almost without leaving the delightful macadam road. New Hampshire has taken up the good-roads movement since automobiles began to throng its highways. So far it has worked in a small way, building pieces of road here and there with the co-operation of the local authorities. But the Granite State is now proposing to branch out on a larger scale, by constructing three trunk lines of State highway over the routes most traveled by motorists. One of these will begin at Portsmouth and extend up through the Ossipees and through the Crawford Notch of the White Mountains. The second will be through the Merrimac Valley, taking in the important cities of Nashua, Manchester and Concord. The third route will be that of the "Ideal tour," up through the Connecticut Valley. Maine has not yet felt the demand for good roads as strongly as some of the other States, but the strength of motoring is growing in the Pine Tree State, as indicated by the vigorous shows that have been held in Portland and in Bangor, and there is little doubt that soon there will be improved roads along the main lines of vehicular traffic. Vermont also has felt the necessity of catering to the growing number of citizens and visitors who use the modern method of travel, and Rhode Island has done much in providing roads.

Connecticut is constantly extending its macadam highways, and disputes with Massachusetts for supremacy in having the most complete system. So far all the New England States have been working along lines of their own, suiting their road building to local needs, but now it is seriously proposed that they work in unison to provide a series of through trunk routes, so as to give autoists continuous good roads from one State into another. Thus, it may not be so very far in the future when the visiting motorist may have the best of highways, from the time he reaches the western boundary lines of Connecticut or Massachusetts, until he reaches his destination at a Maine seaside resort, or a White or Green Mountain retreat. There is just one shadow on this fair picture of New England as the motorist's Utopia, for the best of roads, no matter how well constructed, wear out under heavy traffic and, it is claimed by some, more rapidly under the swiftly moving and heavy motor cars than under horses and horse-drawn vehicles. Authorities argue that, in order that they may enjoy the sport, motorists must have good roads, but if they have them, and aid in wearing them out they should contribute toward their restoration. Therefore, there is a very strong movement, in several of the New England States, toward increasing the tax that is imposed on automobiles under the name of a registration fee. The most popular method of doing this is the graded horsepower tax included in the proposed uniform law.

Automobiles have been sold so long and in such quantities in the New England States that it would seem almost as if the buying power of the public must be exhausted, or that everybody of means must be supplied, but the contrary seems to be the case. It would be hard to find a dealer who does not predict that 1909 will be the biggest year yet. Trade has been good all through the Winter, and there is every proospect that it will hold good throughout the Spring. Many a dealer, who took a liberal allotment of cars last Summer, has been clamoring at the factory for more to satisfy his customers, and people who visit the Boston show with their minds made up to buy some popular model and with money in their pockets will find that the very best they can get is a late May or a June delivery. One prominent Boston dealer, who has the larger part of New England as his territory, will go into the show with more than 400 cars actually sold this season. Good business is not in isolated cases, but

is to be found all along the line and the demand is from all parts of New England. Few of the dealers in the best known cars have had as many enclosed cars as they could have sold during the Winter months, and they now find themselves in much the same position in respect to the more popular types of touring cars. It does not seem to matter much, this year, whether a dealer has a $4,000 car or one at $500—the demand is strong.

There are, naturally, more customers for the low-priced than for the high-priced cars. If anything, the touring car is the more popular model this year, purchasers apparently caring less for the roadster than they did when it was more of a novelty, and the newest four-seated rigs have not caught on with very much promise of popularity. It is surprising, say Boston dealers, whose operations extend all over New England, the number of machines the smaller cities and the country districts are taking this season. The demand outside the large cities is very heavy.

SOME PREVIOUS HISTORY OF BOSTON SHOWS

BOSTON, March 4.—The exhibition of motor vehicles and their accessories, which will be opened in Mechanics' Building on Saturday evening, is called the seventh annual Boston automobile show, under the auspices of the Boston Automobile Dealers' Association. This is a correct statement, so far as it goes, for the dealers' association was organized in 1902 and held its first show the following year. But in giving the impression that Boston automobile shows date back only seven years it is incorrect, for the first exhibition of automobiles in Boston took place in 1898, eleven years ago, and it was held in Mechanics' Building, where the present show is housed.

The 1898 exhibition was a sort of side-show of the Mechanics' Fair, an industrial exposition held usually every three years by the Massachusetts Charitable Mechanics' Association. The main floors of the building were occupied with displays of all sorts of machinery and apparatus of various sorts, but down in one corner of the basement, in a space not larger than is occupied now by any of a dozen large concerns, was the "horseless carriage" exhibit. The display was visited by many people and the Massachusetts Charitable Mechanics' Association offered prizes aggregating $1,100 for automobile events one afternoon during the fair at the Charles River bicycle track, then in its glory. For several years after the first display of automobiles in Boston there were annual exhibits in connection with some larger production, like a food fair, the promoters being glad to obtain two or three of the crude vehicles of that day as curiosities.

In 1901 a group of promoters came to the city and proposed to have a big show of automobiles in Mechanics' Building. The manufacturers, however, had not been educated up to paying the prices for show space that prevail nowadays, and they were staggered by the cost of exhibiting. Few of them, therefore, took kindly to the automobile show proposition, and the grand display amounted to little. The public did not patronize it very generously and those that went saw comparatively few machines. By the time the next year came around, however, Boston had an automobile club, which desired to be as prominent as possible, and a strong nucleus of dealers in the city got together and proposed to run the 1902 show. They were not over-ambitious and were content to secure for their show a section of Mechanics' Building, in which a large fair was being held. The clubmen and the dealers co-operated and worked for the success of the show, and for its size, it was interesting. There was a street parade of automobiles, the cars starting at Mechanics' Building and passing through the business section of the city. There were steam, electric and gasoline cars in line, and the public took much interest in the parade.

It was during the progress of the 1902 show that the dealers formed an organization for the purpose of co-operation in trade matters and for show promotion. But despite the advance the industry and the trade had made by 1903 the first exhibition of that year was not successful. The failure was attributed to the inability of the clubmen, who had assisted in the previous show, and the dealers to work together. In the early Winter they decided to have a union show, but it developed very soon that both parties to the scheme wanted to be in charge, and the result was the usual one—they separated. The clubmen, who were practically all private owners, organized the New England Automobile Association and secured the main hall of Mechanics' Building for a week in February, when the New England Kennel Club was using the rest of the building for its dog show. Very few of the dealers put cars in this show with the result that the display was made up largely of privately owned cars, and the chief attractions were "stunts" which were performed in a small ring and in the open space in the center of the hall.

The first show held exclusively by the dealers was in March of 1903, and it took place in Symphony Hall. There were about eight spaces, and the exhibit included the Darracq, Franklin, Crestmobile, Rambler, Eclipse, Northern, Winton, White, Columbia, Peerless, Baker electric, Locomobile, Pope-Robinson, Prescott steamer, Stevens-Duryea, Knox, Renault, De Dion, Autocar, Oldsmobile, Packard, Stanley, Upton, Waltham and a few others. The descendants of some of these cars will be seen in the coming Boston show; others have passed almost from memory. The show lasted a week and was very successful, the gate receipts exceeding the expectations of the promoters. Symphony Hall was also used for the 1904 show, which was held by the dealers' association, but more of the building was required than the previous year and there was a more comprehensive display of automobiles, motorcycles and motor boats. This show saw the beginning of uniform decorations at automobile shows, a practice used ever since in Boston.

When preparations began for the 1905 show it was apparent that Symphony Hall would not be large enough to hold all the exhibits, and the association moved down to Mechanics' Building, taking the whole structure for a week in March. That year there was a split among the dealers, and some of them conducted a separate shown in Symphony Hall. The main show was successful, while the smaller show did not have a very large attendance. In 1906 both Mechanics' Building and Symphony Hall were used for show purposes, the Symphony Hall space being taken largely by the representatives of imported cars. That year Horticultural Hall, which had been used previously for motor boats, was not taken, the motor boat division being in the basement of Mechanics' Building. The 1906 show was a great success and the halls were crowded all through the week.

It was in 1907 that Manager Chester I. Campbell conceived the idea of a New England apple orchard as the setting for the automobile show, and his success in carrying out that idea was notable. The demand for space was greater than ever, two years ago, and the management was compelled to take a lease of Horticultural Hall to accommodate all who wished to exhibit automobiles, motor boats and accessories. That plan of having one part of the show separated from the main exhibit was never successful, and though everything possible was done in 1907 to induce people to visit the Horticultural Hall display the attendance was not very good. The main display in Mechanics' Building was crowded steadily. Before the end of the show week, however, it became clear that the automobile and the motor boat had reached the parting of the ways. The automobile trade has become so large, and the Boston show was recognized by the manufacturers as so important, that the entire space in Mechanics' Building was needed. On the other hand, the motor boat people objected to being crowded into the basement with inadequate space, and with the counter-attraction better placed in the same building. They, therefore, decided to go their own way, and last year held the first separate show of motor boats.

BAY STATERS IN NEW HOME

L. R. Speare
President

Hotel Carlton
Home of Bay State Club.

J. Fortesque
Secretary

BOSTON, March 1.—Housed in the beautiful Carlton Hotel on Boylston street at the entrance to the park system, occupying the major portion of the ground floor, in quarters which in this city are acknowledged to be the most commodious and richly decorated clubrooms in Boston, the Bay State Association is luxuriously and comfortably now at home, with surroundings that will increase its popularity among its members and consequently broaden the scope of its activities.

The history of the Bay State Association has been intimately linked with its clubhouse features, having moved several times from place to place, as the membership increased and required more room, and as the importance of the organization in automobiling circles grew. Like many other now prosperous bodies, it began its existence in a very quiet and unostentatious manner. In December of 1904 a few of the prominent automobilists of Boston thought the time was ripe for an active association to promote and protect motoring interests, when legislators were threatening the passage of hostile bills.

Another object of the association was to further the automobile industry by the promotion of tours, contests and races. How well it has succeeded is now well known to the automobile world. At its start it was fortunate to possess such prominent motorists as Harlan W. Whipple, Elliot C. Lee, both past presidents of the American Automobile Association; L. R. Speare, president then and now of the Bay Staters, first president of the National body; H. L. Bowden, and F. Tudor.

During the first years of its existence its location was at the Lenox Hotel, but this place soon proved inadequate to accommodate the rapidly increased membership, and the casino of the Woodland Park Hotel, at Auburndale, was secured. This, in its turn, was soon found insufficient to answer the requirements of the membership of 600 which the association had reached. A committee was chosen to select a suitable house in the city, and the association took possession of 282 Dartmouth street, one of the choicest locations in Boston. After occupying this place for two years, the present location was suggested and taken.

The Carlton was erected at a cost of half a million dollars by its present owner, Gardner H. Shaw, and in addition he expended $10,000 on the alterations and decorations of the clubrooms. A number of beautiful rooms were set aside and specially furnished and finished. The café is excellent, and the billiard room is unique, being furnished in dark green oak to represent old hand-hewn timbers, paneled in the same style, with a heavy beamed ceiling and an antique fireplace. A special entrance has been constructed of marble for the use of the members. There is a large waiting room joining the secretary's office, and large rotunda, used for a reading room. The design of this room is Colonial.

The present officers are: Lewis R. Speare, president; Harlan W. Whipple, vice-president; J. S. Hathaway, treasurer; J. Fortesque, secretary; directors, G. W. McNear, Dr. J. F. Hovestadt, F. A. Hinchcliffe, Gardner H. Shaw and C. F. Whitney.

BOSTON AS A MOTOR MART FOR NEW ENGLAND

BOSTON, March 4.—The automobile trade in Boston, like most other things in the Hub, is conservative; it is not subject to sky-rocketing and sudden changes, and a firm once established is pretty sure to stay in business, subject to the ordinary changes. For this reason changes are not frequent, and in the automobile district it is easy to find men who have been handling the same car for a long series of years, some of them dating back to the very earliest days. That not a single Boston automobile firm of recognized standing came to grief during the trying times of last winter, when from all over the country came reports of failures, is strong testimony of the strength of the local trade.

Geographically the trade has spread out, the agents and branches taking larger quarters as their business has increased. Almost anybody who has been familiar with the local trade for a few years back can remember when the major part of the automobiles were sold in old railroad sheds and other inexpensive quarters in the vicinity of Park Square. Only the most courageous dealers occupied stores along Columbus avenue, and they in the main were bicycle dealers who had taken on the automobile as a side line, but who depended upon the bicycle trade for the larger part of their income.

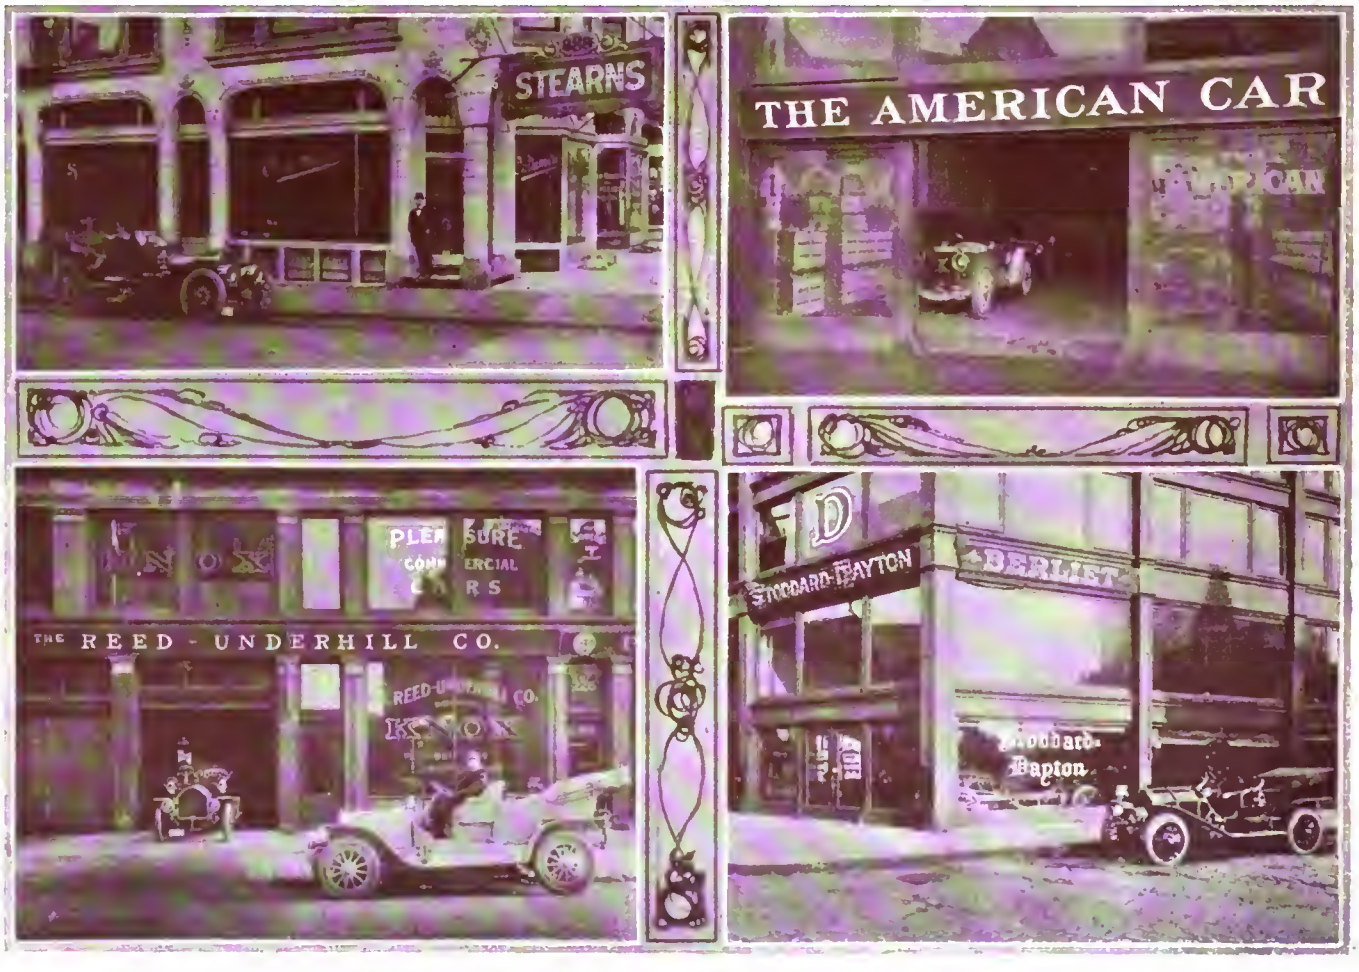
How Boston's Auto Trade Has Changed Location.

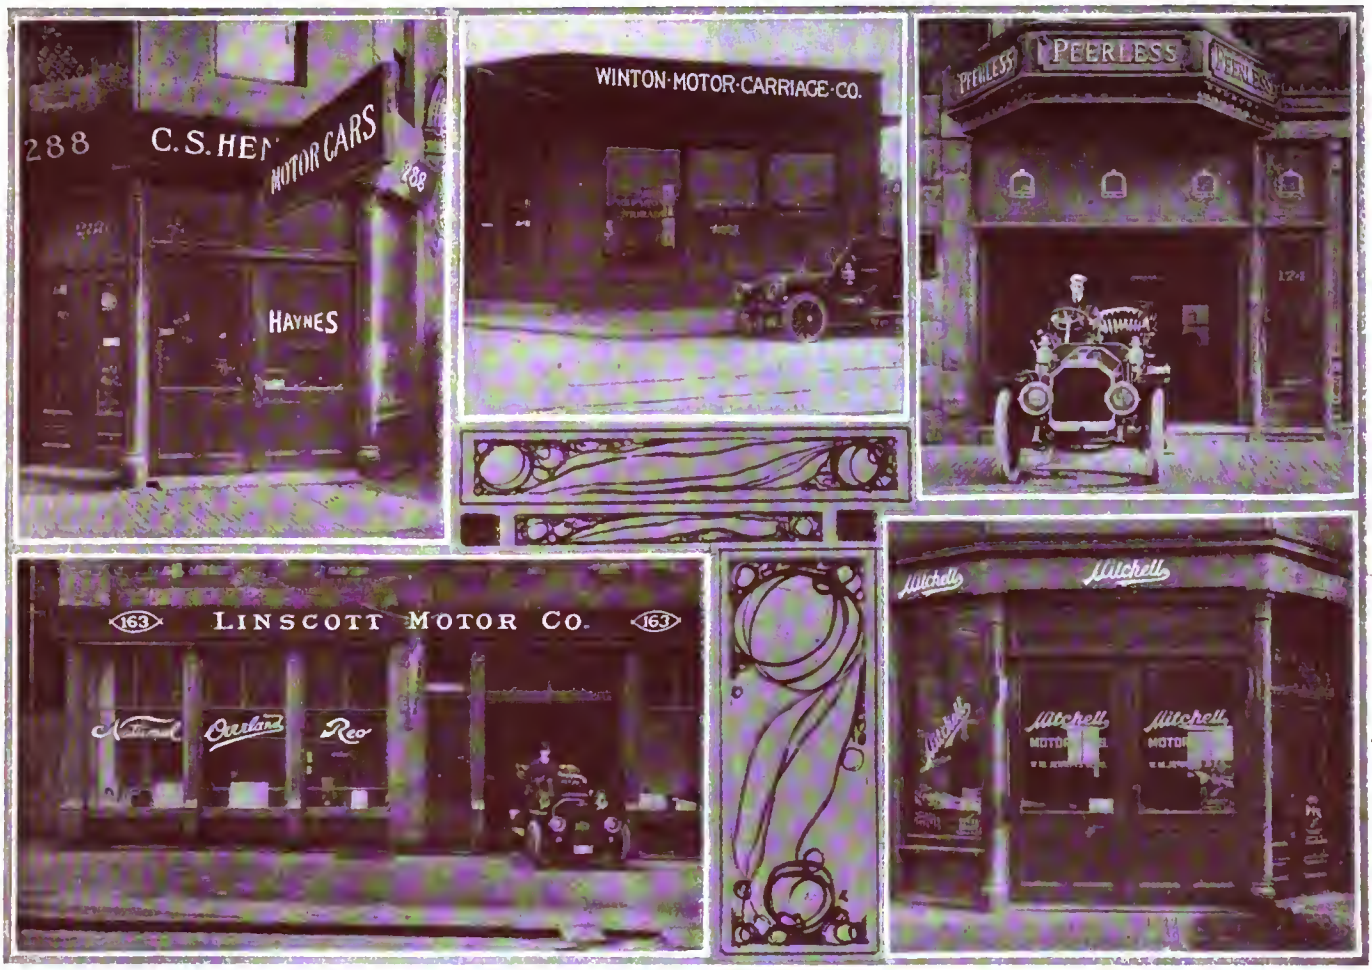
In late years all this has changed, and the automobile district extends from Massachusetts avenue on the south to Park Square on the north, a distance of a mile and a half. Along upper Boylston street the owners of property cannot rebuild fast enough to supply automobile salesrooms, even at the very high rents that are charged. It is along Boylston street that the greatest growth has taken place during the past year, and there are now in process of reconstruction a number of buildings which, when completed, will be occupied by automobile or accessories' dealers. The great demands for space in the locality have been evidenced by the many requests for information.

Some Trade Changes Since the Last Show.

Since the last show several concerns have gone out of business or been succeeded by others with different names. The Harry Fosdick Company, which used to handle the Atlas and the Springfield, retired, and the F. E. Randall Company, which had the Pennsylvania and Pullman agencies, is also no longer on the trade list. The W. A. Frederick Company has been succeeded by the American Automobile Company, and the E. P. Blake Company has given up the retail end of the Jackson business, retaining only the wholesale department. The Columbia Motor Vehicle Company, the branch of the Electric Vehicle Company, has been closed, and recently Morgan B. Kent, the Stearns agent, withdrew, John H. MacAlman taking the agency. The Shawmut Motor Car Company, whose activities have been greatly hampered by a fire in its factory at Stoneham, no longer has a Boston salesroom, its Boylston street quarters being occupied now by the Michelin Tire Company. The Buick Motor Car Company's branch has succeeded Stranahan-Eldridge Company as the sales representative of the Buick. The Dragon Motor Company branch closed with the company, and the Morrison & Price Company, agents for the Rainier and Wayne, dissolved.

There are in Boston practically three score agencies and branches, and they represent 75 different makes of cars, a larger number than in any previous year. Affiliated with the trade in one way or another are some 350 concerns. There are nearly a

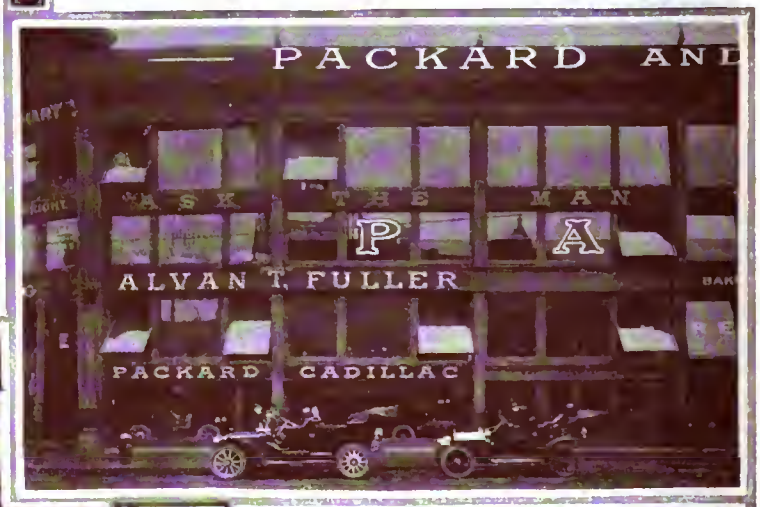


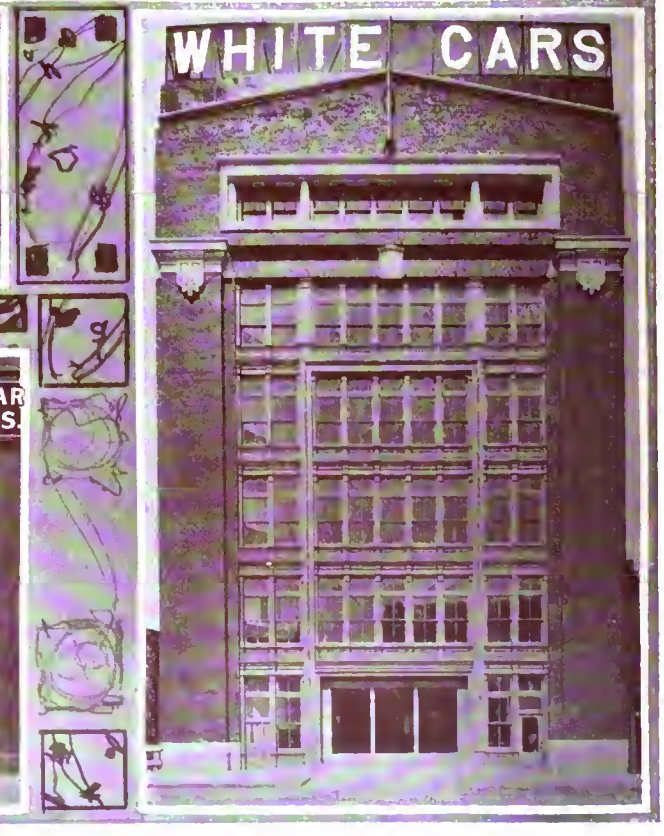


score of large garages. A complete list of the Boston automobile trade and the street locations is herewith appended:

Sewing Machine Supply Co., 22 Lincoln St.	Inter-State.
Harry S. Merry, 24 Tennyson St.	Jackson.
American Automobile Co., Motor Mart.	American.
Auto Motor Co., 11 Park Sq.	Pennsylvania, Regal.
Curtis-Hawkins Co., Motor Mart.	Chadwick, Speedwell.
Buick Motor Co., Motor Mart.	Buick.
Alvan T. Fuller, Motor Mart.	Packard, Cadillac.
F. E. Wing Motor Car Co., Motor Mart.	Marmon.
Crown Motor Car Co., Motor Mart.	Pullman, Glide.
Park Square Auto Station, Motor Mart.	Alco, Stoddard-Dayton.
General Automobile Co., Motor Mart.	Holsman.
Boston Motor Car Co., Motor Mart.	Acme.
Everett S. Litchfield, Motor Mart.	Austin.
George H. Lowe, 11 Park Sq.	Gyroscope.
Fred S. Smith, 38 Columbus Ave.	Apperson, Autocar, Oakland.
Ford Motor Co., 147 Columbus Ave.	Ford.
George J. Dunham Co., 188 Columbus Ave.	Royal Tourist.
Peerless Motor Car Co., 176 Columbus Ave.	Peerless.
Linscott Motor Co., 163 Columbus Ave.	National, Overland, Reo.
Winton Motor Carriage Co., 148 Berkeley St.	Winton.
Reed-Underhill Co., 222 Columbus Ave.	Knox.
W. M. Jenkins Co., 286 Columbus Ave.	Mitchell.
C. S. Henshaw, 288 Columbus Ave.	Haynes.
F. R. Parker, 243 Columbus Ave.	Elmore.
Locomobile Company of America, 589 Boylston St	Locomobile.
Franklin Automobile Co., 671 Boylston St.	Franklin.
Kissel Kar Kompany, 741 Boylston St.	Kissel Kar.
Mills-Kennedy Co., 733 Boylston St.	Welch.
J. W. Maguire Co., 745 Boylston St.	Pierce.
Fiat Automobile Co., 885 Boylston St.	Fiat.
Bartlett & Jacobs, 887 Boylston St.	Allen-Kingston.
J. H. MacAlman, 889 Boylston St.	Columbia, Stearns.
H. C. & C. D. Castle, 893 Boylston St.	Lozier.
Whitten-Gilmore Co., 907 Boylston St.	Thomas, Chalmers.
J. W. Bowman Co., 911 Boylston St.	Stevens-Duryea.
Hol-Tan Co., Hereford St.	Lancia.
The White Company, 320 Newbury St.	White.
Premier Boston Depot, 1008 Boylston St.	Premier, Selden.
Studebaker Bros. Co., 1020 Boylston St.	Studebaker, E-M-F.
Maxwell-Briscoe Boston Co., 121 Massachusetts Ave.	Maxwell.
Grout Auto Co., 117 Massachusetts Ave.	Grout.
Algonquin Motor Car Co., 97 Massachusetts Ave.	Oldsmobile.
Thomas B. Jeffery & Co., 93 Massachusetts Ave.	Rambler.
Panhard & Levassor, 92 Massachusetts Ave.	Panhard.
Roy E. Faye, Quincy Sq., Cambridge.	Matheson.
Alfred Cutler Morse, Motor Mart.	Renault.
Dodge Motor Vehicle Co., Irvington St.	Pope-Hartford, Waverley.
Butler Motor Car Co., Harcourt St.	Rapid.
French Carriage Co., 92 Summer St.	Clement, Bailey.
South End Motor Car Co., 24 E. Concord St.	Brush, Atlas.
C. A. Eaton, 64 Pembroke St.	Lambert.
D. P. Nichols & Co., 11 Edgewood St.	Frayer-Miller.
A. F. Neale, Motor Mart.	Baker.
G. H. Proctor Supply Co., 25 Irvington St.	Mora.
Stanley Motor Carriage Co., Newton.	Stanley.
The G. H. Pixley Co., 239 Columbus Ave.	Pixley.
Stanley Webster Co., 1024 Boylston St.	Pittsburg.
General Vehicle Co., 84 State St.	Electric trucks.

These vacancies in the trade list have been more than filled by new agencies. The Sewing Machine Supply Company, of 22 Lincoln Street, has taken the Inter State agency with Victor A. Charles, formerly Rambler branch manager, as its agent. Harry S. Merry, of 24 Tennyson street, is now in charge of the Jackson retail sales, and the Auto Motor Company is a new firm that





handles the Pennsylvania and the Regal-Detroit. George H. Lowe, the veteran dealer, is connected with the Gyroscope. The Crown Motor Car Company has lately taken on the Pullman line, and Fred S. Smith has added the Oakland to his agency, which includes that for the Apperson and the Autocar. George J. Dunham has left the city to become president of the Royal Tourist Company, but his name remains in the George J. Dunham Company, Royal Tourist agents. The Linscott Motor Company has added the Overland to the National and the Reo. J. H. MacAlman now represents the Stearns as well as the Columbia, and the Kissel Kar Kompany is a newcomer during the year, succeeding the H. C. Stratton Company. The Studebaker branch has the E-M-F. agency and Grout Motor Car Company has the agency for that car.

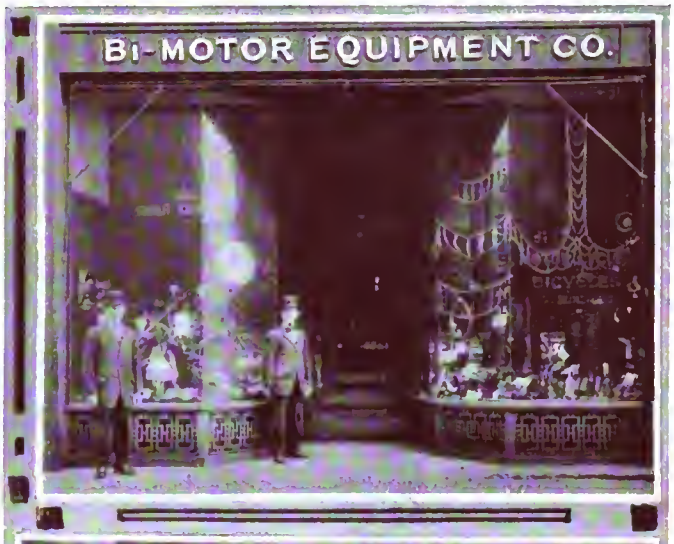
Branch Houses of Leading Makers Are Plentiful.

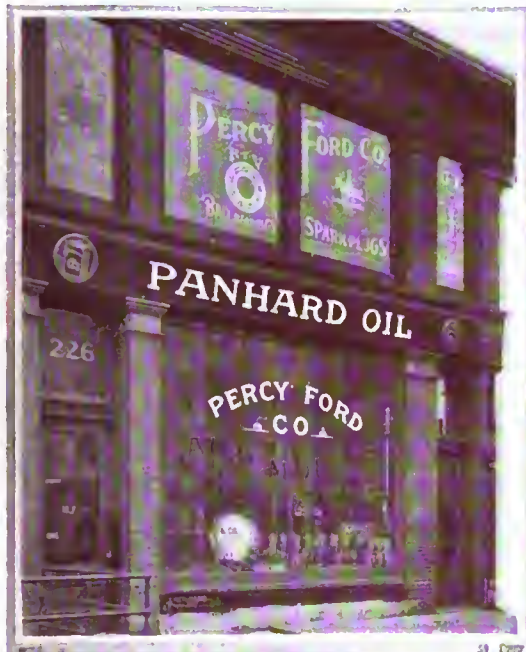
Many of the leading manufacturers maintain branches in Boston, such as the Ford, Buick, Peerless, Winton, Locomobile, Franklin, White, Premier, Studebaker, Maxwell and Rambler. The importers are also well represented. The Panhard & Levassor, Hol-Tan Company and Fiat have branches, and there are agencies handling the Renault, Hotchkiss and other cars

from abroad. The personnel of the trade has changed but little. Alvan T. Fuller, of the Packard and Cadillac; J. W. Maguire, of the Pierce, and F. E. Wing, of the Marmon, are some of the longest established dealers who have handled the same cars for years. J. W. Bowman, the Stevens-Duryea agent, is comparatively a newcomer, having been in business here only two years, but he has won a high place in the local trade and is considered one of the largest dealers in the city. The Reed-Underhill Company, the Knox agents, date back to the early days.

ENDURANCE RUN FOR DETROIT DEALERS

DETROIT, March 1.—An outgrowth of the local automobile show is a four-day endurance run that will be given by the Detroit Automobile Dealers' Association, April 27 to 30. The first day's run will be to Port Huron and return; the second to Jackson and back; third to Lansing and return; fourth to Pontiac, Rochester, Orion, Oxford, Lapeer, Flint, Fenton, Holly, Clarkston, Pontiac and back to Detroit. A day's mileage under these schedules would be from 100 miles up, and suitable prizes will be awarded in the three classes into which entrants will be divided. Cars will be parked each night around the Tuller Hotel.





Maxwell Demonstrating Models that Are Making a Tour of New England, Visiting the Agencies, Under Their Own Power.

MAXWELL SHOW CARS ON PARADE.

Boston, March 4.—A distinct novelty in a demonstrating or show campaign has been started throughout New England by the Maxwell-Briscoe Boston Company, that of going to nearly all of the important towns, and first parading the new models with all the local Maxwells in a decorated procession, and then of showing the new members in the evening at the headquarters of the various agents.

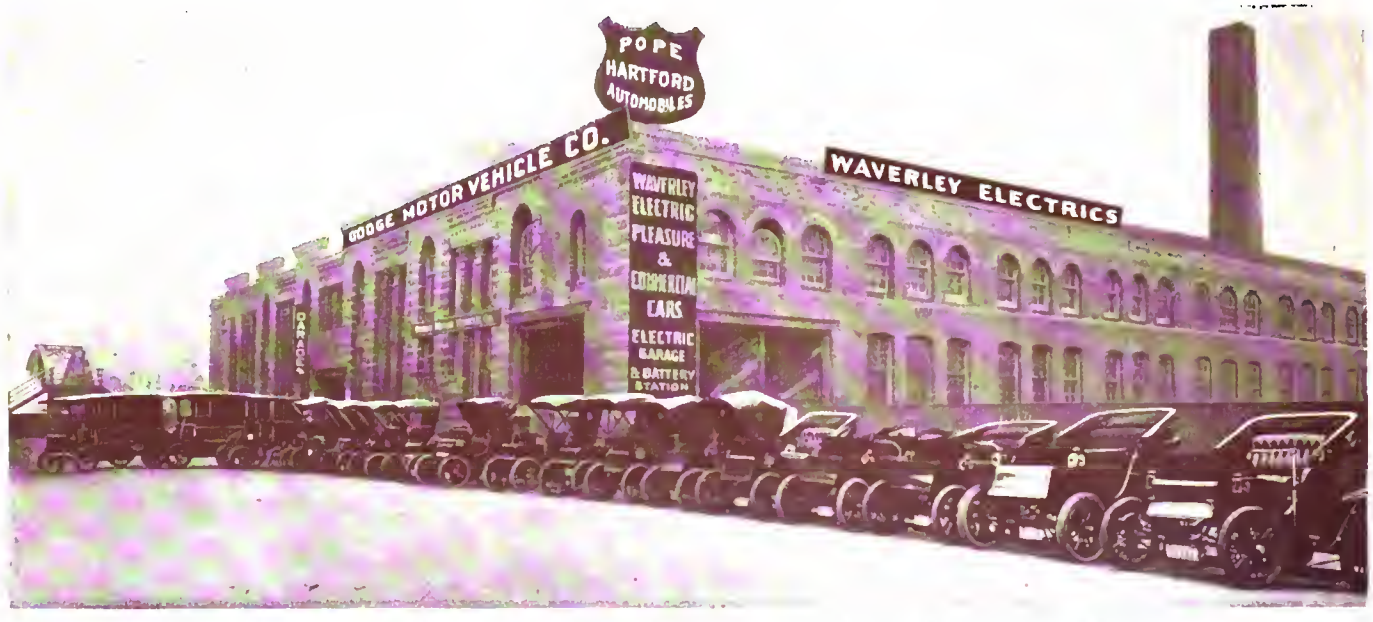
Ford and Lyon, the Fitchburg Maxwell agents, originated the scheme for a three-day show in January, with a parade each day, between the hours of 12 and 1, of the new models and all the local cars available, covering the business and residential streets, after which the 1909 cars were on exhibition during the afternoon and evening. The result was so profitable that the Boston branch decided to go all over New England, taking the cars under their own power from place to place.

The following towns and cities were visited: In Massachusetts, Malden, Brockton, Worcester, Fall River, Taunton, Waltham, Haverhill, Peabody, Springfield, Milford, Maynard, Webster, New Bedford, Attleboro, Lowell, Lawrence, Gloucester and Holyoke, and Woonsocket and Providence in Rhode Island. After the Boston show the cars will again be sent upon the road.

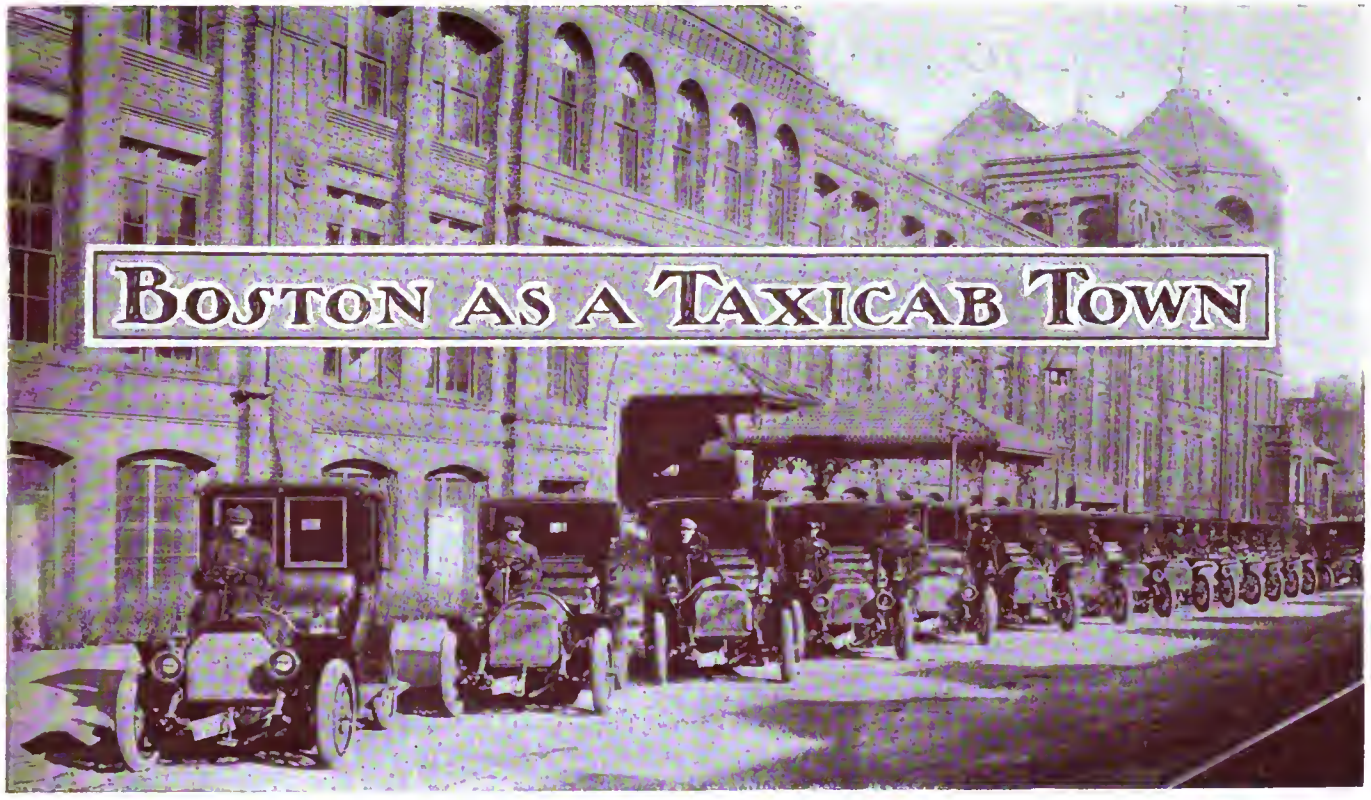
GARAGE FOR ELECTRIC CARS ALONE.

Boston, March 4.—As a result of the great increase in the use of electric automobiles in this city in recent months, there has been built here for the Dodge Motor Vehicle Company, the Boston agent for Waverly electrics, the largest garage and battery station for electric cars in the east. Mr. Benway, of the local concern in speaking of the great increase in business and the building of the new place, said, "The erection of this structure will facilitate our caring for practically any number of electric cars and our force of battery experts and electricians, who are familiar with all makes of storage batteries and electric vehicles, places us in a position to turn out work pertaining to them better than ever before. We are able to do work promptly and at lowest prices, and in addition to repairing or caring for cars, we are now building sparking and vehicle batteries of our own, guaranteed as to life and mileage per charge.

"This, with our line of Waverly electrics, including ten models of pleasure cars ranging in price from $1,150 to $2,150, has placed us in a position to please anyone looking for electrics. We have found many who have wished to buy cars of this type of motive power but who did not do so until a special garage and business for them was opened."



A Leading Boston Garage that Is Exclusively Devoted to the Sale and Storage of Electric Automobiles.



Equipment of the Taxi-Service Company of Boston, Which Will Have the Exclusive Taxicab Service Privilege for the Boston Show.

BOSTON, March 4.—Taxicab use in this city, according to A. E. Morrison, has undergone much change in recent months, so that instead of proving a failure where they had not been successfully used before, they have proven exceedingly popular and now really a necessity in transportation. The Taxi-Service Company, the largest in the field, began operating its Berliet cabs on September 1 of last year, and after six months of work its experience has shown that Bostonians appreciate this quick method of getting from place to place.

Facing an outlay of enormous sums of money for machines and equipment, and with warnings of failure from the records of other concerns which had tried the business, it was freely predicted that success would be impossible, especially because there was already one other company in the field and not room for two. Time has proven the fallacies of these opinions, for the new firm now has forty-three cabs in this city alone, with twenty-five more coming at a rate of five each week, covering the entire field around the city, including the leading hotels, theatres, stations and other places where it is natural to find persons to whom the use of taxicabs is now necessary, or at least convenient.

With H. Bradford Lewis as president, George F. Smith as vice-president, John M. Stewart as treasurer, and A. E. Morrison as manager, and a great deal of courage to face the obstacles thrown up, the company started in the fall and its judgment has proven sound by the phenomenal success of the enterprise. There are few transportation companies which pay for a long time after beginning, but the caxicabs immediately found favor with the public, and the expenses for operating the cars on the very first day were covered by the receipts. The financial condition of the company is now splendid, for it owns every one of its cabs and is able to pay dividends upon its stock.

Knowing the mistake of false economy in purchasing cheap or untried equipment, the highest grades of cabs were thoroughly investigated, both as to quality and appearance, without special regard to price, feeling that an expensive machine might be the more economical in the end, through lack of necessity for extensive and frequent repairs. A powerful car was required, with ample seating capacity, and one that could be used by any one without feeling that a cheap-looking machine was being employed. The product of the American Locomotive Company, the Berliet cab, was selected, and again the sound judgment of the firm was shown, for these machines have given the excellent service and low up-keep expense promised by the makers.

To distinguish them from competitors, the door of each has been painted a dull yellow, and they can be readily recognized at some distance. So much business has developed that at times only about 90 per cent. of it can be handled, though, of course, each succeeding week, with its arrival of five cars, is showing less of a loss of the business that calls for taxicabs. The company controls the service at the hotels Lenox. Thorndike, Brewster, Boston Tavern, Tuilleries and Empire and the National Shawmut bank, besides meeting all trains at the South Terminal Station, and following up service desired at many other places in and around the Hub.

Having made a success of its work here, the Taxi-Service Company some time ago decided to branch out and is now operating ten Berliet cabs in Providence, R. I., and has just established a branch company in New York City, taking over the service of the Waldorf-Astoria, the Holland House and five smaller hotels. It is operating sixty automobiles and two hundred horses in caring for the business there, and the horses will be displaced as fast as the cabs can be secured. The cabs have proven much more economical and efficient than the horse-drawn vehicles.

The management of the Boston show has shown confidence in the Taxi-Service Company and the realization that the crowds who visit the big exhibition will be calling for cabs, by arranging to give this concern the exclusive service rights at the show, to handle the immense amount of business that will arise there. A uniformed starter will be in attendance day and night, while the doors are open, to answer questions and to supply cabs. It is the intention of the taxi management to give a most thorough service to the autoists who will visit the show, and extra cabs will be used if they can possibly be obtained from the makers.

One hundred machines are expected to be in use by the first of July, a number which is thought to be sufficient for the requirements of the Boston public for some time to come.

MAINE, TOO, HAS A GOOD AUTOMOBILE SHOW

PORTLAND, ME., March 1.—Portland has another automobile show to its credit, the fourth annual, which concluded Saturday evening, and was more successful than any of the three previous ones. As in the case of all the others, this show was held in the spacious Auditorium, which was profusely decorated for the occasion. The exhibition opened Monday, February 22, and continued the rest of the week. Though the weather was not at all satisfactory for the greater number of days, there were large crowds present at all times and they came from all parts of the State.

The fourth annual show was not quite as large as some of the previous ones, but everything considered it was a much more satisfactory one. All the exhibitors were there for business and almost a record number of sales were recorded for the week. Agents were present at all times and there were few who did not take a number of orders during the week.

Though most of the cars exhibited at the show have been seen in the city before, there were several newcomers. Perhaps the most notable of these was the appearance of the high-wheeled Black machines, which proved a source of great interest to all the visitors, and aroused no little comment. The Marion car, one of which was driven over the road from New York to Portland, was also on exhibition and elicited a good deal of favorable comment.

The Maine Taxicab Co. has just been formed in this city to use the Palmer type of public carriage, and these were shown for the first time. The taxicab will be seen on the streets of the city this summer, and there is every indication that it will be extremely popular not only with the residents of Portland but with the hundreds of visitors who come here every summer.

Portland's streets were covered with ice, and for the most part were in horrible condition during the week of the show, but this did not prevent the demonstrators from getting out with their cars, and the city was filled with buzzing, speeding machines during the six days of the show.

While there were plenty of automobiles on exhibition, the number of motorboats was rather small, for there were but three large ones shown in the basement. These embraced the speed, cruising and ordinary pleasure types. They were beautiful pieces of workmanship and attracted plenty of attention. Frederick M. Prescott had charge of the show, and showed his ability in the excellent arrangement of booths and the beautiful decorations of evergreen, palms and bunting. The principal exhibitors at the show were the following:

F. A. Nickerson & Co., Pierce Great Arrow and Oldsmobile; L. C. Gilson Auto Co., Mitchell and Stanley automobiles; Buick Automobile Co., Buick cars; Harmon Automobile Co., Thomas, Chalmers-Detroit, Franklin and White cars; New England Motor Sales Co., Marion automobiles; Palmer Bros., Gasoline engines and boats; Portland Shipbuilding Co., boats; Taxicab Company of Maine, taxicabs; W. L. Blake & Co., marine engines and oils; George D. Thorndike, Mianus engines; Thomas Laughlin Co., marine hardware; F. H. Little Oil Co., oils; Vacuum Oil Co., oils; C. F. Guptill Co., marine supplies; The Portland Co., Knox automobiles; L. Calvin Miller, Black motor vehicles; Valvoline Oil Co., oils; Dresser & McKenney, marine carpenters; J. A. Salmon & Co., monograms; Borne Scrymser Co., oils; James Bailey Co., automobile accessories; Maine Motor Carriage Co., Stevens-Duryea and Peerless cars; Stoughton & Folkins, Maxwell cars; C. F. Roper & Co., safety propellers; Frank M. Low & Co., clothing; Gordon Automobile Supply Co.; F. F. Wentworth, Overland automobiles; Darling Automobile Co., Reo automobiles; Simmons White Co., marine motors; French Leather Novelty Co.; Marine Motor Manufacturing Co.; Bath Marine Construction Co.; Studebaker Co., electrical vehicles; Rice Brothers, motor boats; Underhay Oil Co.; Harris Oil Co.

It is with the greatest of satisfaction that the automobile dealers of Maine view the prospects for the coming year. The panic of last year hit this section of the country a very light blow, so there is little danger that the sales will be light. From all indications, the chances are that there will be more machines sold this season than in any previous year. Already there are over three thousand automobiles owned in Maine, and it is confidently predicted that the four thousand mark will be reached this year. The spread of the good roads movement has been responsible, to a great degree, for the growing popularity of automobiles here.

MERRY BANQUET OF HARTFORD DEALERS.

HARTFORD, CONN., March 1.—During the show week in this city the Hartford Automobile Dealers' Association held a banquet at the Allyn House, convening after the doors of the show had closed on last Thursday evening.

The banquet equipment included Maxwell cocktail, Simplex-in-cup, Packard with Stevens-Duryea on the Side, Broiled Buick Hen on Pierce-Arrow Toast, Thomas Salad, American with Stoddard-Dayton Demi (Overland) Tasse. The list of oils included Autocar appetizer, Ford Sherry, White Steamer Champagne, Oldsmobile Highball, with decorations in Mitchell style. Ignition was by Franklin cigars, Knox, Cadillac and E-M-F cigarettes.

President Ralph D. Britton of the dealers' association presided as toastmaster. The first to respond was Mayor Hooker, who proved a witty speaker. But Assessor P. Davis Oakey, as tax assessor, could not quite comprehend why the Mayor should have placed a valuation of $500 on his $4,000 car. State Highway Commission James H. MacDonald enlightened the multitude on the State road improvement problem and introduced many facts and figures, all of which he had at his fingers' ends. P. E. Curtiss, automobile editor of the Hartford Times, proved a marvel of wit, and Walter S. Schutz paid a glowing tribute to the work of the State Highway Commission.

MILWAUKEE SHOW DATES EXTENDED.

MILWAUKEE, March 1.—The first annual Milwaukee auto show, scheduled to open Thursday, March 11, and end March 13, will be made a four-day affair, it is now certain. The Milwaukee Automobile Club has found so much interest in the show that it is assured of bigger success if the time is extended into the next week. One hundred cars, at least, will be exhibited, forty agents having taken space, and a number of others cannot be crowded in. The accessory and motor cycle spaces are also filled. The big Hippodrome is not large enough to accommodate all. The balcony must be used for car exhibits, and additions will be built to make room for the accessories that will be crowded out.

PLANS FOR TOLEDO SHOW UNDER WAY.

TOLEDO, O., March 1.—Arrangements are well under way for the annual automobile show of the Toledo Automobile Dealers' Association, which was incorporated some time ago. The dates set for the event are March 22 to 27, inclusive, and the affair will be held in the Coliseum, the same hall where the show was held last year. Committees are now at work, and instead of being divided as at that time, all the local dealers are interested and will participate. This assures a much larger show than has yet been undertaken in this city.

CLEVELAND, March 1.—Saturday night, to the strains of "Home, Swect Home" and "Farewell," the lights winked out the seventh annual Cleveland automobile show—the largest, most artistic and most successful ever held in the State.

Early in the evening the work of dismantling exhibits commenced. Big canvas covers were produced, cars were enveloped and shot out through the big Lakeside Avenue entrance. Before the crowd was away nearly one-third of the cars were either lined up outside or on big drays being carted away. Just before the close Robertson's Band paraded the main floor. With rousing, old time tunes, it serenaded first the Thomas "round-the-world" exhibit, and then around the entire line. The march was accompanied by the tooting of horns, the organ-like notes of the Gabriel and the cheers of the crowd.

Cleveland and Clevelanders can well be proud of the 1909 show. To say that it was a great success would only be repeating what has been said before. There was not a hitch. Everything was conducted in a systematic manner that was above criticism. Good will was the dominant feature. There has been rivalry, of course, but of the good fellowship kind.

It is estimated that upward of 50,000 people attended during the week. There was difficulty in getting around at times. The sales closed up as a direct result of the show will number hundreds. It has not only been an automobile show of Cleveland, but of the entire northern part of the State. Visitors have been drawn by hundreds from neighboring cities. No one has been disappointed. Cleveland dealers are more than pleased and manufacturers satisfied. The show has brought results.

FURTHER PLANS FOR CARNIVAL WEEK.

To ratify the various plans, which had been made up to that time, by the carnival committee of the New York Automobile Tradc Association, a large mass meeting of the members of the trade was held last Thursday evening in the Automobile Club of America audience room. The ideas followed out by the committee met with the hearty approval of the members, and further plans were discussed. It is probable that in addition to the hill climb on thc Fort George Hill, and the day parade on Saturday of the week, April 5 to 10, that there will also be speed trials on the Ocean Parkway, special tests and an aeronautical exhibit at Morris Park, an opening dinner for trade members and a wind-up smoker at the Automobile Club of America.

To meet the expenses it will be necessary to raise between $15,000 and $20,000, and of this about $2,500 was subscribed at the meeting. An additional committee of ten was nominated, to assist Gen. John T. Cutting, chairman of the finance committee, composed of the following: E. W. Bonham, Goodrich tires; F. M. Hadley, Knox; Harvey Adams, Auto Supply Co.; W. J. Coghlan, Moon; F. M. White, Stewart Speedometer; George F. Hare, Olds; Oscar Hausen and Richard F. Fenker, Parkway Garage Co.; W. C. Poertner, National; Harry Pyke, Chalmers-Detroit, and A. J. Interrieden, Warner Instrument Co.

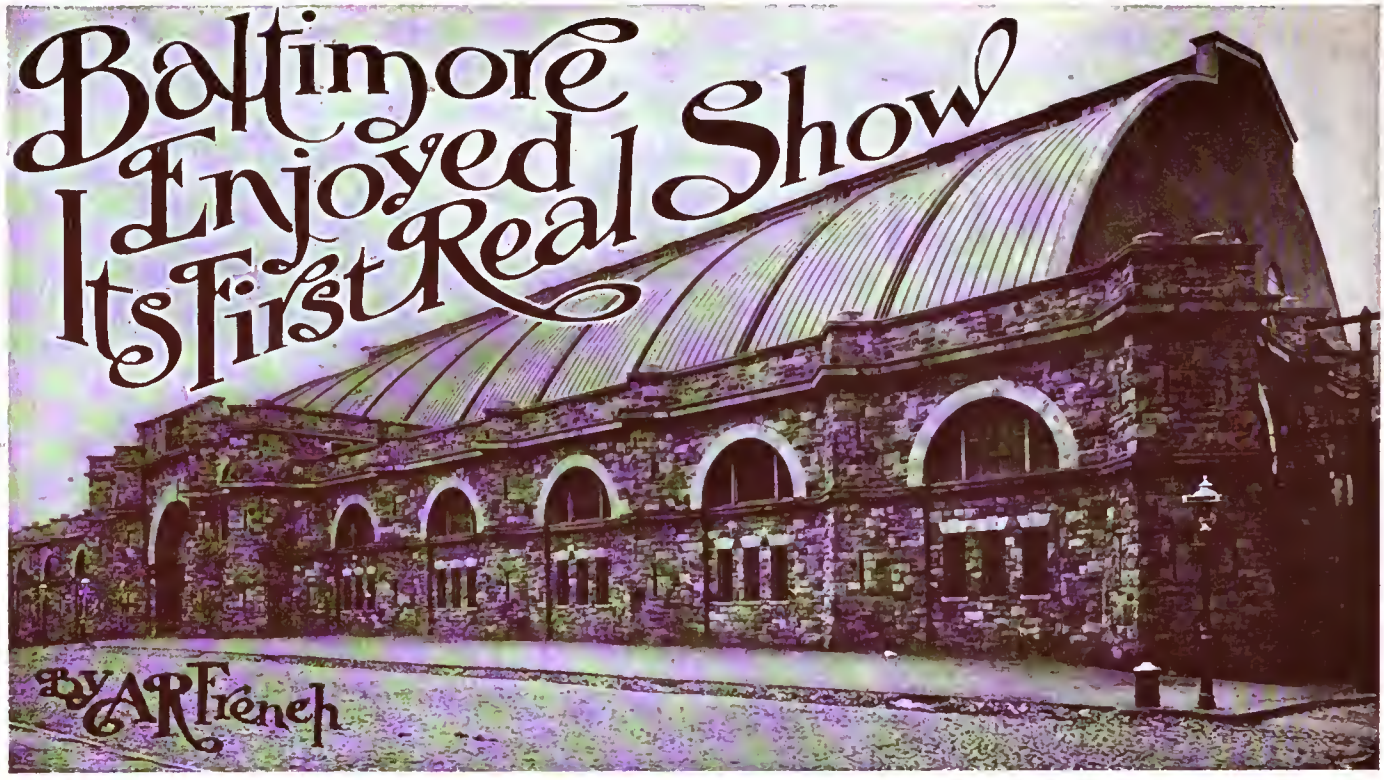
AUTO SHOW FOR NORTHERN NEW YORK.

GLENS FALLS, N. Y., March 1.—In the three-story garage of the Glens Falls Automobile Company, from March 15 to 20, there will be held an exhibition of a number of well-known makes of cars that will probably draw interest from a large section of this part of the State. The building will be especially decorated for the occasion and an orchestra will be in attendance each evening. Among the cars which will surely be shown are the following: Thomas, Knox, Regal-Detroit, Overland, Maxwell, Franklin, Oldsmobile, Pope-Hartford, Pierce Great Arrow and Cadillac. The New York-to-Paris race-winning Thomas is expected, and there will be a number of accessories shown.

MINNEAPOLIS NEEDS MORE SHOW SPACE.

MINNEAPOLIS, March 1.—In answer to a great demand for space in the automobile show, which will be held here from March 13 to 20, the management is now trying to rearrange the plan of exhibits, to accommodate all who wish to be included among the exhibitors. Elaborate plans are being made for the entertainment features of the show, and it is confidently expected that the week will draw thousands of people to this city from all over the Northwest.

Baltimore Enjoyed Its First Real Show



Fifth Regiment Armory, Where Baltimore's Fourth Annual Automobile Show Was Held Last Week.

BALTIMORE, March 1.—The first automobile show given under the auspices of the Automobile Club of Maryland, and the fourth affair of the kind held in Baltimore, opened last Wednesday afternoon and closed Saturday night at the Fifth Regiment Armory. It can truthfully be said that Baltimore really had a show this year, for everything went off in perfect harmony, the displays were numerous and of the highest order, and there was no cramping of exhibitors nor crowding of visitors. While there was not a dearth of room in the Armory, it was arranged in a comfortable and easy manner, the exhibits displayed to advantage and with sufficient room for the crowds to walk along without any congestion.

There were many more cars shown than ever before, just 120 being on the floor of the regimental hall, with 44 exhibitors. This includes in addition to the automobile dealers, those engaged in the accessories and tires trade, motors, motor boats, motorcycles, etc. The show was more than a local exhibition, as was the case in former years, for there were visitors from all sections of the State, as well as from the Southern States and nearby Northern and Western States. Of course, the crowd for the most part was made up of Maryland motorists, but there was a big representation from the South. The dealers have been jubilant since the close, for they made more sales and have more prospects than at any previous show. They do not hesitate to say that the present exhibition has done much to make the holding of a show in Baltimore an annual affair, with dealers and owners alike, and that future events of the kind will be left to the good management of the club.

This opinion has, however, arisen only since the opening, for previous to the undertaking by the club the dealers had decided to do away with shows in the future here, considering the New York, Chicago, and Philadelphia exhibitions enough to satisfy the Baltimoreans. They were simply discouraged by the poor success they met with at previous exhibitions, but evidently Baltimore has a rekindled epidemic of the motoring fever, and the increase in the number of cars owned here within the last year has been remarkable. The fact that the club succeeded in getting the Fifth Regiment Armory for the bolding of the event was a great help in making the celebration such a pleasing one in every way. Heretofore the dealers and visitors had to be contented with smaller halls entirely unadapted for such a purpose.

Among the novelties from a Baltimore standpoint was the exhibition of the French Renault, the first foreign car ever shown here, and, in fact, the first one to be represented here. Two styles of this car were at the booth of the Stoddard-Dayton Baltimore Auto Company, the $8,750 landaulet and the runabout which sells for $1,750.

Two Baltimore cars were on exhibition, the Spoerer car, manufactured by the Carl Spoerer's Sons Company, who entered the trade last fall, and the Maryland car, made by the Sinclair-Scott Company, which has been in the motoring field for several years. One car of each of these makes was shown, both being fully equipped touring cars with tops, the Spoerer selling for $2,850 and the Maryland for $2,500. The Spoerer has a four-cylinder water-cooled motor, 4 1-2-inch bore and 5-inch stroke, with cylinders cast separately and a five-bearing crankshaft. The transmission is of the three-speed selective type, and the gears made of Krupp nickel steel throughout, running on Hess-Bright bearings. The front axle is of I-beam section with Timken roller bearings, while the rear axle is a floating one in a pressed-steel housing. The ignition is by the Bosch dual system.

Another practically new car on the market, and a Maryland product, was the Burns car, manufactured by Burns Brothers, of Havre de Grace, Md., who have also been in the business only since last fall. The car which this company makes is styled a transformable coupe, resembling a physician's carriage, and is particularly for service on country roads. The engine is of 14 horsepower with double opposed air-cooled cylinders under hood. The car has a wheel steer, with gas and spark control on top. The axles are of the Timken roller bearing types, front and rear, the springs full elliptic and the wheels are high, 40 inches front and 42 inches rear, with solid or cushion tires.

Other cars new in the show line to Baltimore were the Rauch & Lang electric, the Palmer-Singer, Lozier, Reo, Oakland, Chalmers-Detroit, E. M. F., Rambler, Brush and Gaeth. Commercial cars were poorly represented, the Brush package cart and mail car and the Hart-Kraft $1,200 commercial delivery wagon of 18 horsepower, at the booth of Little Joe Weisenfeld, who has just entered the motor car business with the Reo and Oakland agencies, being the only ones shown. The newest thing in the accessories line was the autolight igniter and con-

troller, patented by the International Manufacturing Company, of this city. This is a device for lighting and controlling gas lights on an automobile, which enables the driver to control the light from the seat. It was demonstrated on a KisselKar.

Howard A. French had a big line of Indian and Pierce motorcycles of the 1909 style at his booth. Frank B. Burton displayed for the first time here Vim motors and a motor boat manufactured by the Niagara Motor Boat Company, of North Tonawanda, N. Y. James G. B. Davy & Company gave out automobile directories of this State, containing the list of license numbers of each owner and arranged in the order of the numbers from 1 to 8,077. The Brush single cylinder runabout, which made a run from Detroit to a number of eastern cities last Summer, attracted considerable interest.

The following is the list of exhibitors:

Shaffer Manufacturing Company—Pullman.
White Garage Company—White steamer.
Brush-Nichols Company, Washington, D. C.—Brush.
Ford Auto Company—Ford.
F. W. Sandruck—Gaeth.
J. L. B. Wilhide—Kissel Kar.
Charles F. Houghton—Overland.
Burns Brothers, of Havre de Grace, Md.—Burns.
Maryland Rwy. and Electric Supply Co.—Witherbee igniter, electric devices.
Baltimore Rubber Tire Co.—Kelly-Springfield tires.
Hector C. MacRae—Champion accumulator.
Automobile College.
Automobile Club of Maryland.
Edw. A. Cassidy & Co.—Jones' speedometer, Monogram oil.
Frank D. Burton—Vim motor, Niagara power boats.
Howard A. French—Indian & Pierce motor cycles.
Jones' Machine Company—Keystone automobile grease.
National Sporting Goods and Auto Apparel Company.
H. A. Broadbelt, Jr.—Stanley steam car.
Standard Oil Company.
E. R. Elliott & Co.—Automobile insurance.
Thomas G. Young—Stearns.
Mount Vernon Motor Car Company—Autocar.
James G. B. Davy & Co.—Accessories.
W. P. Shuler—Mitchell.
Sinclair-Scott Company—Maryland.
Auto Equipment Co.—Rambler, accessories, Continental tires.
Bridge Garage Company—Cadillac.
Carl Spoerer's Sons Co.—Spoerer, Goodyear and Diamond tires
Stoddard-Dayton Balto. Auto Co.—Renault, Stoddard-Dayton.
Baltimore Buggy Top Co.—Automobile and buggy tops.
Lambert Auto Company—Maxwell.
Motor Car Company—Thomas, Stevens-Duryea, E-M-F.
Zell Motor Car Company—Peerless, Chalmers-Detroit.
Little Joe Weisenfeld—Oakland, Reo.
Winton Motor Carriage Company—Winton.
Rice's Garage—Welsh, Pennsylvania, Rauch and Lang.
Mar-Del Mobile Company—Packard, Franklin, Waverley.
Auto Outing Company—Buick, Palmer-Singer.
Olds Motor Works Branch—Oldsmobile.
Foss-Hughes Motor Car Company—Pierce Great Arrow.
Southern Auto Company—Lozier, Pope-Hartford.
Dixon C. Walker—Studebaker.
Great Eastern Optical Company—Accessories.

MARYLAND CLUBS TO FIGHT TAX.

BALTIMORE, March 1.—At the convention of automobile owners in this State on Saturday morning, under the auspices of the Automobile Club of Maryland, to discuss the special tax feature of the automobile bill prepared for the Maryland Automobile Commission by Col. Sherlock Swann for presentation to the next General Assembly, a plan for forming a general State club to fight the passage of its obnoxious features was unanimously adopted. This club will consist of local councils in every important city and town and in all of the counties.

There was a decided political tinge to the convention, and the proceedings were animated throughout. President Rowe, of the club, started things going by asking the several hundred delegates whether, as a last resort, they would take up the fight for what they consider their rights with their ballots. The answer was unanimously in the affirmative. "We can muster nearly 8,000 voters," declared Dr. Rowe, "and that means something. When we show the members of the General Assembly that we are affecting their parties we can, no doubt, get a hearing. While I believe it is but fair to pay a nominal registration fee to maintain the bureau of registration, I do not see why the owners of automobiles should be compelled to bear all the expenses of maintaining good roads, when horse-drawn vehicles do equal, if not greater damage to the thoroughfares. And then, just now, the good roads in this State exist only in imagination and on paper, and we would pay tax for the maintenance of such roads."

In behalf of the members of the Hagerstown Automobile Club, W. B. Littleton explained that the special tax in Washington County would work a great hardship to the autoists of that section. All the roads there are toll roads, the county is so close to adjoining States that the several licenses necessary make the cost of automobiling almost prohibitive.

The Massive Baltimore Armory's Interior Was Effectively Decorated and the Exhibits Were Well Massed.

BUFFALO'S SHOW A SPLENDID SUCCESS

BUFFALO, March 3.—Convention Hall is aglow with the greatest automobile show that Buffalo has ever witnessed, the seventh effort of its kind, and the first under the exclusive direction of the Automobile Club of Buffalo, opened on Monday evening by President John M. Satterfield in a brief speech, punctuated by choruses of "honks" from the 122 motor cars exhibited by the 38 dealers. Secretary Dai H. Lewis was, as usual, in general charge of the arrangements, and the club made the effort of its life in the way of decorations, the chief effect being constellations of stars, gleaming in golden galaxies from the ceiling, a field of pink.

The hall was found totally inadequate for the applications for space. Even the ante-rooms were pressed into service for the exhibitors, and, in one instance, the space renter found himself so crowded for room that he hung one of his runabouts up in the air over the rest, taking the entire stage at that.

The show has representatives of the principal cars of American make, and one that was never exhibited before. This is a car made in Buffalo, the Austin Lyman Special, a six-cylinder, 60-horsepower, four-passenger car, with a toy tonneau, warranted to sustain a speed of 70 miles an hour. The price is $3,000. It is the first of its kind, made by the Austin Lyman Company, Terrace and Erie streets, Buffalo.

The electrics are represented by the Babcock Electric Carriage Company, the Waverley and the R & L electric.

The Pierce Arrow Motor Company exhibit nothing but six-cylinder cars, the feature of the display being the green Louis XVI, $12,500 limousine shown in New York.

The E. R. Thomas Motor Company shows a full line of big six five-passenger flyabouts, little six cylinders, four-cylinder landaulets and 20-horsepower broughams.

The Automobile Club also had an exhibit, consisting of road signs, to indicate distances and danger points, and of membership blanks handled by capable membership solicitors.

A novelty at the show is an automatic automobile protector designed by a Buffalo woman, Mrs. S. C. Partington. It is an automobile cover of canvas suspended from the roof or ceiling of the garage and lowered or raised over the car by a pulley.

A Rambler and chassis, two Reos, two Overlands, a Regal and Premier are shown in one exhibit. Another agent shows four different makes, the Stevens-Duryea, Knox, Corbin and E-M-F. The Pullman, Crawford and Firestone motor buggies and trucks are the exhibit of another. Twenty-seven trophies won by the Pullman car are shown on a shelf above the cars. A manufacturer of automobile tops and bodies shows a Franklin fleet of five air-cooled cars. The Gaeth shares space with the Oakland and Cartercar and the Oldsmobile foregathers with the Oakland and Rapid. There is a big display of motor trucks, the American Motor Truck Company exhibiting three.

A local company exhibits cylinders cracked and welded together so deftly as to deceive the inexperienced eye in trying to locate the fracture. Broken axles, pistons and frames are also exhibited, united by the same magic electric welding process.

The Peerless and Cadillac are shown side by side and the Maxwell-Briscoe Company uses seven cars to show the varied output of its factories. The Chalmers-Detroit and two Stearns cars are neighbors alongside of a Mitchell and four Stoddard-Daytons. A Winton "Six" and R. & L. electric are exhibited side by side. Then as the visitor proceeds up one aisle and down the next he sees a large Packard exhibit, Pope-Hartford and Selden cars, eight Buicks and Grabowsky power wagon, the Brush runabout and delivery wagons, and a Haynes touring car and chassis, all making a brave showing.

The accessories interested have a large representation, a dozen exhibits showing everything in the line of automobile and chauffeur equipment. The attendance has been large every day and evening. The exhibitors report both large sales and many more prospects.

Pierce-Arrow—Pierce-Arrow Motor Car Co.
Thomas Flyer—E. R. Thomas Motor Co.
Stearns—Mason B. Hatch, 729 Main st.
A. L. S. (Austin Lyman Special)—Austin Lyman Co.
Chalmers-Detroit—Mason B. Hatch 729 Main st.
Cartercar, Gaeth—Louis Engel, Jr., 732 Main st.
Pope-Hartford, Selden—Buffalo Automobile Exchange, 461 Franklin st.
Maxwell—Maxwell-Briscoe Motor Co., 24-28 Goodrich st.
Franklin—Brunn Automobile Co., 1140 Main st.
Stoddard-Dayton, Mitchell—J. A. Cramer, 737 Main st.
Pullman, Crawford—Meyer Carriage & Auto Co., 322 Elitcott st.
Buick—Buick Motor Co., 1100 Main st.
Reo, Regal, Rambler, Premier, Overland—Poppenberg Motor Car Co., 674 Main st.
Peerless, Cadillac—Kane Motor Supply Co., 539 Elitcott st.
Stevens-Duryea, Knox, E-M-F—Co-operative Motor Car Co., 672 Main st.
Winton, R. & L.—Ralph E. Brown Motor Car Co., 721 Main st.
Packard—The Densmore Co.

CARNIVAL WEEK PROGRAM ANNOUNCED

NEW YORK, March 1.—The program for Carnival Week of the New York Automobile Trade Association has been arranged, giving a list of events for every day of the six, from April 5 to 10, with the exception of the Friday, which is Good Friday and a holiday. Monday there will be the hill climb on the Fort George Hill, with Col. K. C. Pardee in charge, as he was last year, when there were 87 entries. Tuesday has been set aside for straightaway races and speed trials on the Ocean Parkway or the Motor Parkway, with C. R. Teaboldt as chairman of the committee for these events.

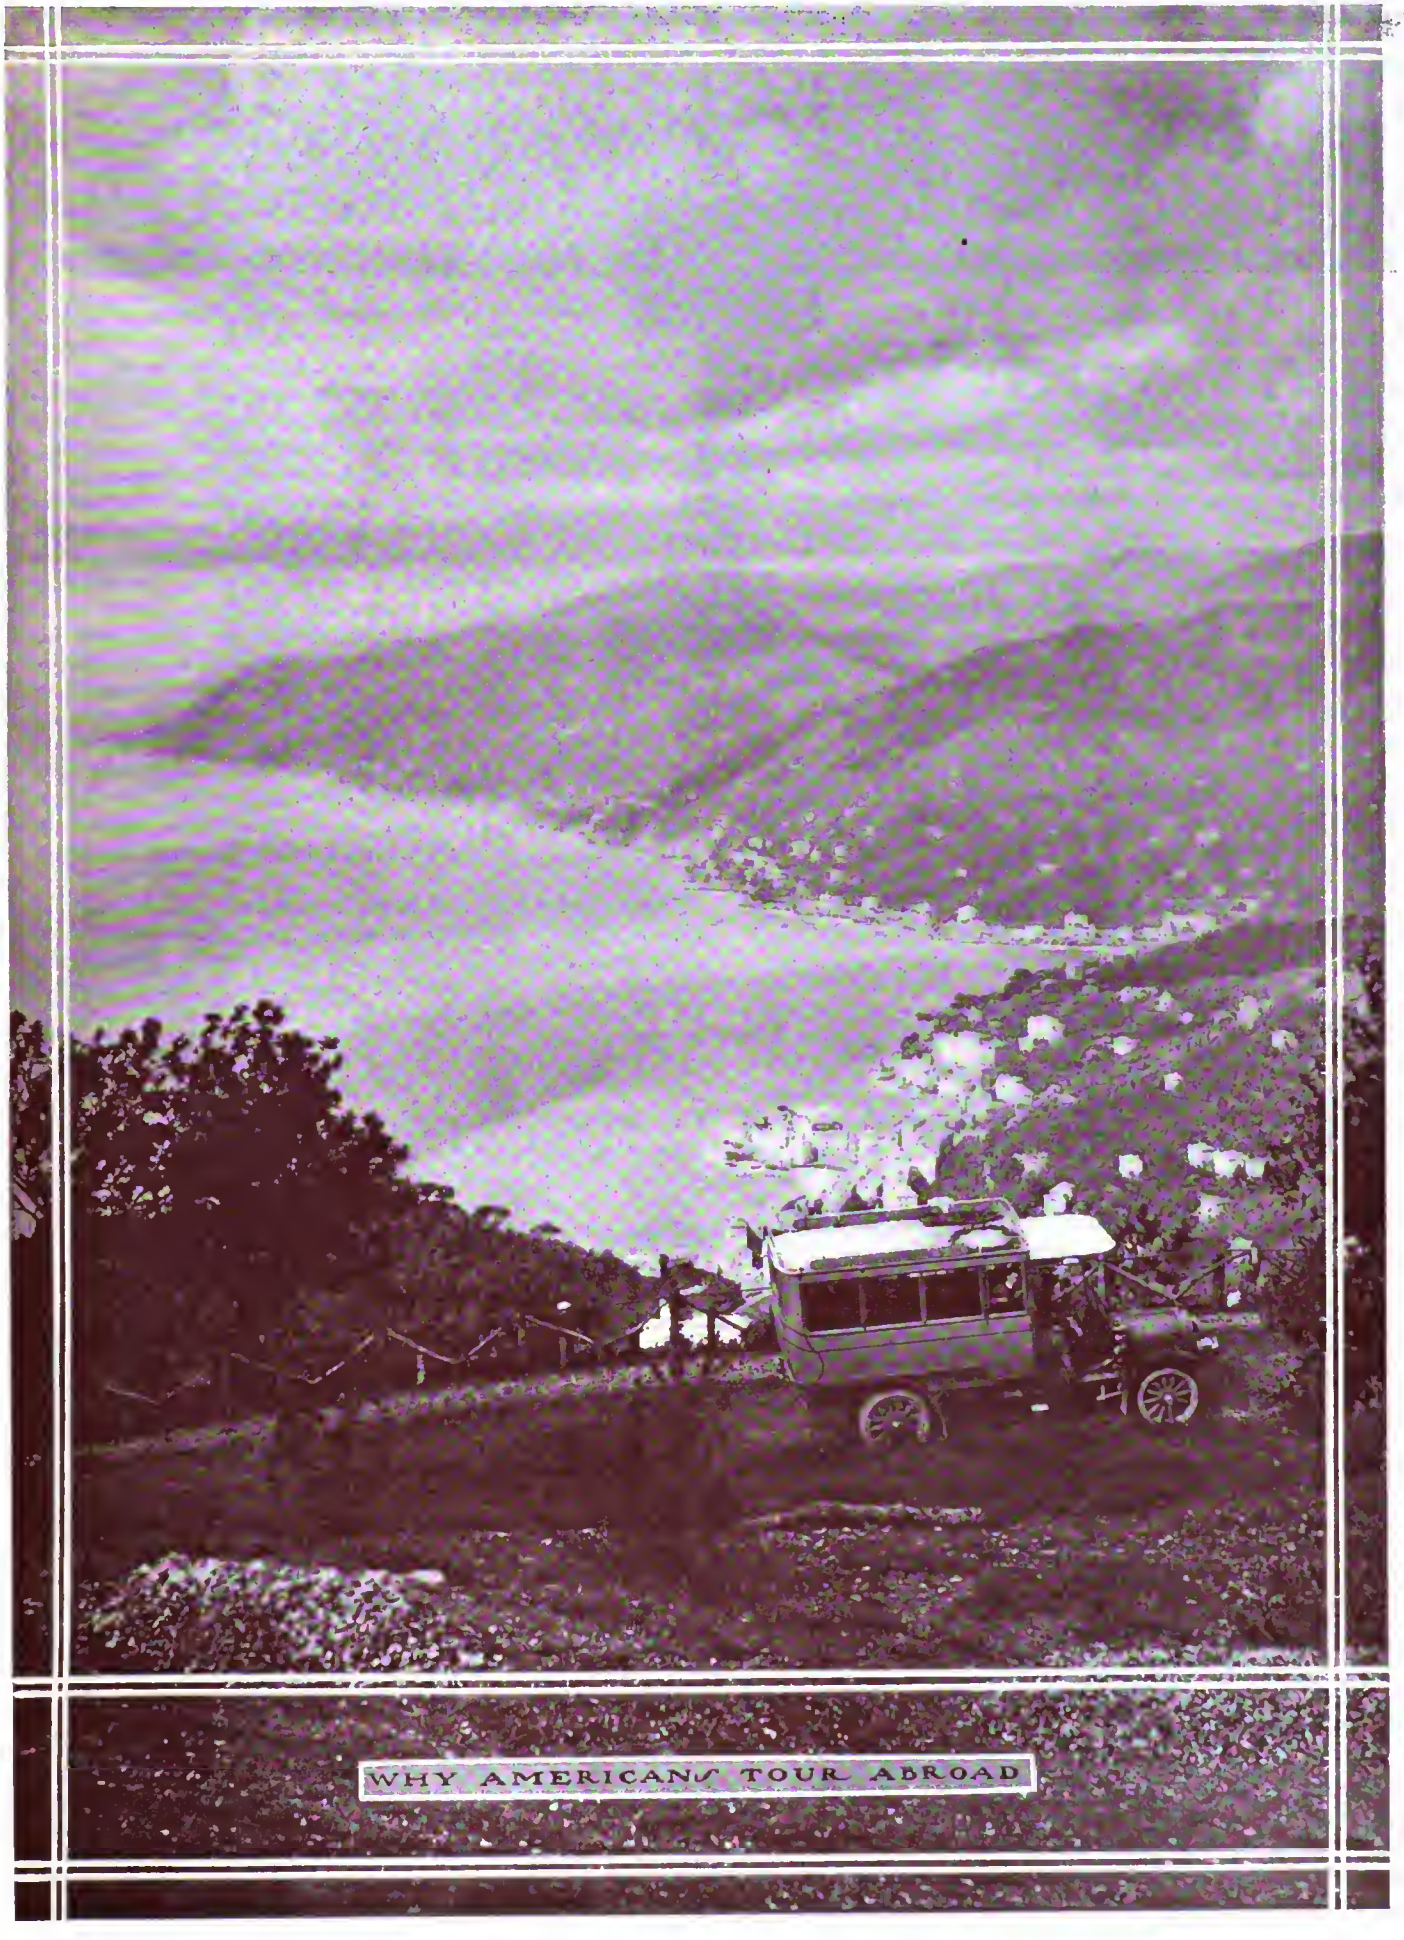
Souvenir Day has been the term given to Wednesday, and the trade will be asked to give to their customers, or owners, suitable souvenirs, banners, or catalogues, and in the evening there will be a trade banquet at some important hostelry. Alex. Howell has been made chairman of the committee for this affair. Special aeroplane events either at Morris Park or some other suitable place will be held on Thursday, with Orrel A. Parker in charge. Saturday will be the great parade day, when it is expected that there will be a greater number of cars in line than last year and some more original and beautiful decorations. Gen. Cutting has announced the acceptance of Gen. Geo. Moore Smith, to act as grand marshal with authority. R. C. Howell is chairman of the committee on arrangements. Saturday evening there will be a meeting at which the various prizes will be presented.

E. R. THOMAS WILL TOUR IN AFRICA.

BUFFALO, March 1.—In a big six-cylinder Thomas limousine of 70 horsepower, E. R. Thomas, of the E. R. Thomas Motor Company, of this city, will tour Egypt and into the interior of that country. The big car and its chauffeur have already left New York for Naples, where Mr. Thomas will be met.

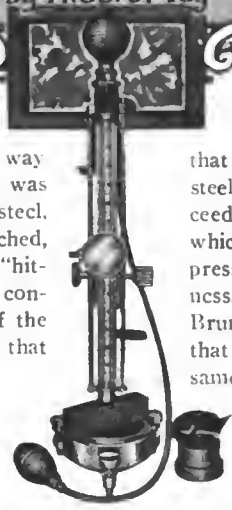
WHY AMERICANS TOUR ABROAD.

The illustration on the adjoining page almost tells its own story as to why so many Americans yearly tour in Europe. The view is in the Italian-Swiss Alps at Portofino-Kulm, and the well-known De Dion-Bouton car, which makes a specialty of mountain climbing, is the automobile included in the picture.



PRINCIPLES OF THE SCLEROSCOPE FOR MEASURING HARDNESS

By Thos. J. Fay



PHYSICAL hardness in steel as it is used in automobile work is a phenomenon which has to be varied to suit the service to be rendered. In the old way of arriving at the facts in relation to this property, it was the custom to take into account the carbon content of steel, and the temperature at which the steel would be quenched, as well as the subsequent annealing process. It was a "hit-and-miss" game at best, on the count that the carbon content is not all to be taken into account, and the bulk of the steel also has to do with the result, even assuming that shape is not a large factor.

The illustration shows the Shore Scleroscope, the main ability of which is to determine the physical hardness of materials, notably steel; which information is valuable, in that it reflects, to a considerable degree, the several other qualities residing in the steel. From the "stylus," with its diamond point (used to scratch the steel, to show its hardness), to the methods of "Brunnell," in which the steel is indented, was a long way, and the indentation of the little (hardened) steel ball, as used in the Brunnell plan, does extremely well by way of indicating the hardness of steel, if the same is soft enough to respond to the process. In the meantime, the "Shore" method (of the subject), comes as a great advance, in that the metal does not have to be scored, indented, to any great extent, or crushed.

Alloy Steel Is the Hardest of All Metals.—In the early days, in which carbon steel was the mainstay, it was not considered difficult to determine the hardness of the steel, particularly in view of the fact that the carbon content was as a good guide; at the present time it is not possible to go by the carbon for the reason, that it is not carbon on which reliance is placed for the great hardness to be noted. Then, it is a fact, that full knowledge of the properties of alloys is not available, and the result is that it is no longer possible to make a good guess, even in the absence of a test, which is but another way for saying that the test, if made, could be gauged, as to its probable accuracy. Owing to the great hardness of alloy steel, tests for hardness are more difficult, especially if it is desired to arrive at conclusions closely approximating the facts. It would be a very difficult process to use a "stylus" on "quenched" alloy steel balls as found in some of the superior ball bearings, or, for that matter, alloy steel as it is used in transmission gears would be beyond the art of the metallurgist equipped with a stylus.

The Shore scleroscope depends for results on the fact that steel will vibrate more or less depending upon its strength, elasticity and hardness, considering a fixed set of relations, taking into account the shape of the specimen used in the test and the manner in which the test is conducted. In the Shore method, then, it is the aim to interpret the hardness of the material in view of the elasticity of the same. But in this will be found much food for serious reflection, in view of the small drop-hammer with which the scleroscope is equipped, and the fact that the minute device could scarcely create more than a ripple in a "molecular sea." It is quite out of the question to assume that the "fiber elasticity," of the material undergoing test, is the phenomenon which is responsible for the accuracy of the scleroscope, in its search for the hardness of material.

Molecular Elasticity and Recuperative Ability.—That the hammer of the instrument searches out the molecular structure, and compels a response to the impact of the hammer, is what seems to be the rational claim. Relative molecular motion must result in local deformation if it is true that recuperative ability is absent. In other words, if the steel is stressed locally, and the stress is so great as to exceed the recuperative ability of the same, it is a "dent" which will be noticed, and in the Brunnell test is the "depression" which is looked upon as an indication of hardness. Under the circumstances, it is probably true that the Brunnell test falls short of accuracy, for the very reason that it breaks down the (molecular) structure, and the same is then incapable of telling the story for the very reason that it is broken down.

Within the elastic limit, materials follow well defined laws, and in working materials it is the aim to keep well within the elastic limit, for the reason that once the material is stressed to the "yield point" it will no longer respond; the laws, of which knowledge is potent, are over-stepped, and the student is lost in a sea of conjecture, with failure heaped about him as the only tangible dividend. In the same way it must be that tests for hardness which destroy the structure fail to tell of the force on the one hand and the resistance (negative force) on the other.

The Problem Savors of Much Complexity.—What is wanted, then is a means for determining the force which would attain permanent deformation of the molecular structure, without actually deforming, in excess of the recuperative ability, since to tell the tale, the material must be in a recuperative state. In other words, the material must not be destroyed in the process, else the information sought will sink into oblivion in company with the form crushed out of the material undergoing test. Even with the Shore Scleroscope, evidence of the inability of metal to respond will be found if the same zone is struck repeatedly; the readings will be different; the structure undergoes change sufficiently to be noticed on an instrument of such nice delicacy.

Impact and Pressure Related.—The instrument takes into account the usual laws of impact in which the impact or blow that a body is capable of delivering after it has acquired momentum, in response to a force, acting during a greater time, is used to conquer a greater force in less time. Were it possible to estimate exactly the ratio of the intervals of time, this ratio would serve to indicate the ratio of the force of impact. Impossible as this would seem to be (since the lesser interval of time is as the infinitesimal increment), renders it desirable to approach the subject from the other point of view and estimate the values involved in the spaces through which the masses move.

In general, it is to say that if W equals the weight of the hammer and h equals the height of fall, Wxh will equal the energy of the blow: that is to say, it will equal the energy residing in the hammer at the instant of contact. The energy will be employed in the manner as follows (a), in compressing the hammer; (b), in compressing the test specimen on which it falls; (c), in compressing the base on which the specimen is rested; (d), to a minute extent in friction, etc.

Plainly, then, account must be taken of the relative hardness of the hammer, which is compressed, and the specimen, which is also compressed; the clamp "should be devised in such a way as not to introduce a notable factor into the calculation. That the relative hardness (of the hammer and the specimen) is not a matter which will defeat the project is assured from the fact that the instrument serves the purpose with lead as well as with

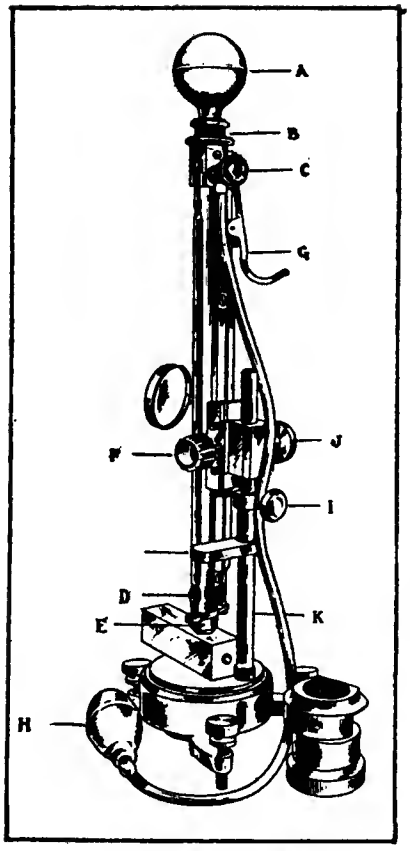


Fig. 1—Explanatory Figure of Instrument.

hardened steel. The great advantage of the instrument lies in the fact that it is capable of measuring the compression of the specimen, and to respond to the compression of the hammer, small as the values are, despite the fact that the feat was looked upon by scientists as quite beyond the pale of human ingenuity.

In view of the wide use to which an instrument such as this might be put, it is extremely important to feel sure of the basis of its application, which, up to the present time, has beeen much discussed, although the conclusions thus far reached fail to impress one as being in full accord with each other, or sufficiently in accord to be regarded as lasting. Even as it is, the question of the effect of crushing the molecular structure, with its consequent effect upon the readings, is one which will have to be investigated at some length, since it is true that the readings will differ if a blow is struck twice on the same spot.

Mathematical Exposé of the Performance.—Assuming the conditions (which must be satisfied) to obtain as follows:

Let

R = the effective resistance of the specimen to be tested;
= the total resistance, less the weight of the members:
S = area of the head of the hammer in contact with the specimen;
P = the pressure, at any instant, exerted between the hammer and the specimen, which ultimately reaches the pressure at the instant of maximum compression of the specimen;
E = modulus of elasticity of the material;
L = depth of the specimen acted upon;
W = weight of the hammer, as before given;
h = height of fall, as before given.

The distance of fall of the hammer. after actual contact, during which the specimen is being compressed, is the compression due to the maximum effort, and will be equal to:

$$\frac{RL}{ES}$$

; which takes into account uniform compression; it is in this connection that speculation will creep in, in that the compression may be so localized as to render an estimate of the distance L difficult to ascertain.

In all events the work performed in compression will be equal to:

$$\frac{R^2L}{2ES}$$

Were it possible to consider a second blow on the same surface, noting the added compression, it would then be fair to pursue the matter at further length, and end by solving for R, which, as before stated, represents the effective resistance of the specimen to be tested. In the absence of this ability it is possible to note on an arbitrary scale in the instrument what may be called relative resistance.

What the Figures Seem to Indicate.—The work performed in the process is as R^2 by the depth L of the molecular disturbance; taking it for granted that the area S, of the zone, is as the area of the hammer in actual contact. The modulus of elasticity of the material will serve to modify the conclusions, in so far as 2ES will have bearing upon the situation, if it is true that the modulus E is a variable in steel, that is to say, a variable of some magnitude. It has never been definitely settled that the modulus E is much different in the several grades of steel, as in alloy steel, relative to carbon steel.

In view of the fact that R^2 will have the greatest influence on the situation, and that S, if small, adds to the efficiency of the scbeme, it is plain to be seen that appreciable readings will follow even if L is of an unassignable magnitude. Since R increases with the hardness of the steel, and R^2 is the value which influences the situation, it would seem as if the harder the steel the more pronounced will be the reading on the scale, although it is true that the diminishing value of L will taper off the readings.

The Results as Reported in Practice.—When a force acts upon a body a secondary force, or a force of reaction, is at once set up, equal and opposite in direction. The hammer is thus brought to rest, and the only phenomenon in which interest is here taken lies in the ability of the steel to resist the force, and snub the motion within the shortest interval of time. On the arbitrary scale, which takes notice of the rebound, the ability of the steel is disclosed, since in the absence of hardness the distance L would be increased, but the value of R would fall away, and since the magnitude is proportional to R^2, it is plain to be seen that rebound would be less pronounced; proof of which lies in the fact that the expenditure of energy would be maximum in the case in which motion is arrested within the shortest distance of travel. In actual practice it is found that with lead the readings are about 2 per cent. of what would obtain with steel under the same conditions. In this is an indication of the working out of the law, showing that the value of R^2 (increasing) is a sign of hardness, while increasing the value of L is by way of reduced hardness. True, the two factors are for hardness, but one increases as the other decreases, and the value which increases as the square is the value which has the most marked effect by way of engendering hardness.

The regular Shore scleroscope is intended to measure the hardness of the hard grades of steel, as medium and high carbon steel, as well as the alloy steel products. In the cases involving soft metals what is called a "magnified hammer" is used. In both cases the hammer weighs but one-twelfth of an ounce, and it is figured that (in view of the area) the hammer is capable of exerting a pressure of 500,000 pounds per square inch. A close in-

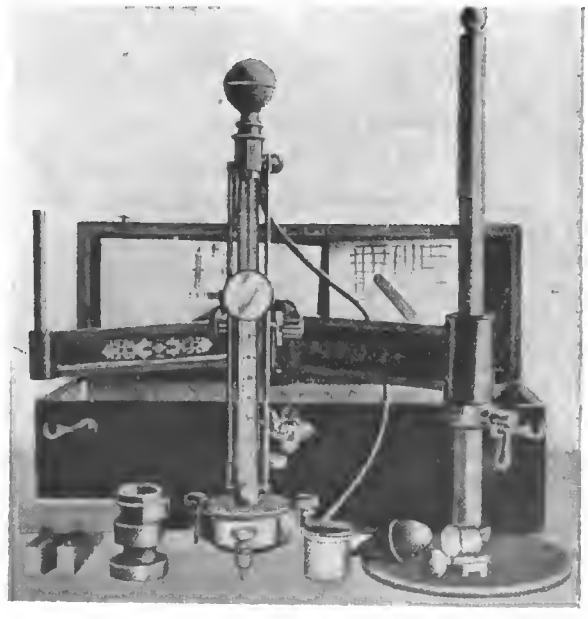

Fig. 2—Showing Instrument and Accessories Furnished.

spection of the formula will disclose the surprising fact that the weight does not have to be great; it is even possible to consider that the weight should not be beyond a certain point. What the formula demands is that the weight should be resisted so that motion will be arrested in the shortest time, and the weight should be so light as to enable the bounce to be measurable. It is fortunate that this is true, for it enables the device to do the work in a manner quite up to the requirements, despite the fact that measurements for hardness were looked upon as difficult to make on a basis of reasonable accuracy.

Range of Possible Uses of the Instrument.—In industrial work in general, there will be many uses for an instrument of this sort, but in the automobile zone of activity it is a question if the instrument may not be used for the specific purpose of determining the state in which the finished parts may reside, with a view to passing upon them. In other words, it may be possible to use the instrument in the testing departments of the various automobile shops, in order to show that the heat-treated products come up to the desired standard.

With a little practice it would seem possible to determine the carbon condition of the steel; if it is in the Martentistic state, for illustration, the instrument would show a hardness accordingly; in the pearlitic, the steel would show the softness to correspond. If a part is intended to be made of, say, chrome nickel steel, and if, through some inadvertence, the part comes out carbon steel, the scleroscope would quickly disclose the fact, merely because the degrees of hardness would fall far short of the hardness due to chrome nickel steel in the hard state.

If a part is to be hard on one surface and soft in general, local heat treatment is necessary, and if in the press of work the hardening operation be overlooked, the inspector armed with an instrument such as this would detect the fact and the result would be for good. In the purchase of steel, the same would be true, in that the test would have to come up to a standard, and if actual tests were to show quite differently, it would be a fair inference that the purchased product would be of a different grade. In the laboratory it would be a great advantage to be able to ascertain the hardness of steel, (a) in the normal state; (b) annealed; (c) quenched, from several temperatures; (d) annealed after quenching, considering several temperatures; and in case-hardening it would be of the greatest advantage to be able to note if the core is soft, and if the shell is hard. That the core should be soft is well understood; and that it does not always come soft is assured. The shell should be hard; as hard as glass (so they say), but it would be a good idea to interpret the statement in terms a little more in keeping with what might be called defined limits.

Portability Is of the Greatest Advantage.—The instrument is quite small, and it is not so delicate as to go out of calibration on small provocation. Fig. 1 shows the instrument with index letters which will help in understanding the brief description as follows:

(a) Set the instrument plumb, by means of the plumb-bob rod, on the right-hand side of the tube D.

(b) Place the piece to be tested under the steel cap of the tube E, which raises up by means of the pinion-knob F.

(c) Lower the instrument to the work; press it down a little, by placing the left-hand thumb on the hook G; this opens the pad valve, thus aborting the vacuum, which would otherwise follow the drop of the hammer, within the tube, and which would affect the rebound, which would in turn influence the accuracy of the instrument.

(d) To release the hammer, press the red rubber bulb H with the right hand, and to know the result observe the rebound; taking the readings just as the weight is in a state of counterpoise.

It will be understood that the weight is raised by means of the rubber bulb A, and in the operation it is necessary to press and then as suddenly release, when with the inrush of air the difference in pressure will result in the weight being sucked up to the top. A suitable catch takes into account the small piston C, with a hardened pin or rod on it, which is adapted to push against a pendulum-like hook pin, which engages with a circular dove-tailed recess in the top of the drop hammer.

The instrument and the parts which go to make up the set will be noted in Fig. 2, and as the user will naturally be supplied with complete instructions as to the mode of proccdure, it will not be necessary to enlarge upon the details here. In this article it is the idea to take into account the situation in general and to point out that the uses to which the instrument can be put may far exceed the original intent.

As a Quick Means of Investigating Steel.—In these days, when nearly all the steel used in automobile work is heat-treated to render it strong, as well as to bring out the much desired kinetic properties, it is not enough to purchase good steel, low in metalloids, and free from such imperfections as steel naturally falls heir to. If the steel has to be heat-treated, and if the carbon content is high enough to markedly effect the qualities of the product, merely because the temperature is even slightly above or below some critical point, this instrument should serve to reduce the chances of going wrong.

It is well understood that the structure of steel will be more or less crystalline, depending upon the temperature at which the same is raised and the rate of cooling of the same. This will be true for all grades of steel, but it will be especially true in cases in which the carbon content is a little high. If the structure is noticeably crystalline, it is then that the performance of the material will be below a desired standard, while in dynamic work failure is almost assured.

Fortunately it is possible to detect a difference in hardness of a given specimen of steel for the several "fracture" conditions. In other words, if the steel is "silky," the hardness will be that for such a structure; if the structure is crystalline, the hardness will fall off, and increasing crystallinity decreases hardness, with the result that the structures which are not kinetic can be detected by a man of no great skill.

What is needed is a set of standards which are known to be in a satisfactory state, in order that the instrument can be used on a comparative basis. In cementing work the question will be a little troublesome, on the ground that the "core" of the cemented structure will not be open to test in some cases. But it will nearly always be possible to grind through the shell at some point and apply the test to the core, with a view to finding out to what extent kinetic qualities reside therein.

It is in this cementing work that there is a need for great accuracy, since the shell can be hard with no assurance that the core will be kinetic. If the shell is hard, it may be what is wanted, but it will be of no avail if the core is brittle, on the count that the part will fail in service. It would be a waste of time to perform the cementing operation at all were it not for the desire to provide against brittleness; several grades of tool-steel will become quite hard enough if the materials are heated and quenched; brittleness is one of the properties in such products.

The instrument will tell the artisan, once he becomes acquainted with the performance of the same, whether or not it will be necessary to subject cemented products to a double treatment with the idea of correcting the core without destroying the hardness of the shell. It is well understood that cemented products can be rendered the more perfect, under certain conditions, if the double quench is resorted to. On the other hand, it is also well understood that the more complex process is liable to go awry, on the ground that if there is a hazard in one operation, there is a double hazard in two such operations. There is one other point which is prominent in the makeup of this instrument, namely, it is not so delicate as not to be handled by men of ordinary skill, and previous training is not so much of a factor. In general it is quite out of the question to entrust such work to men whose training is short of that which would follow some years of work in the laboratory, even assuming that a previous schooling might not be to advantage. In a word then, this instrument is of advantage to the busy practitioner, and its splendid accuracy is not to be destroyed by workmen, who may use the same.

EFFICIENCY OF INTERNAL COMBUSTION MOTORS*

By BERTRAM HOPKINSON, M. A., M. Inst. C. E. (Professor of Mechanism and Applied Mechanics, Cambridge University).

IN a paper read before this Institution two years ago, on the "Influence of Size Upon Thermal Efficiency," Professor Callendar based his conclusions upon a comparison of efficiencies by the Research Committee with the efficiency of a small air-cooled bicycle engine tested by himself. The measurements made then were never questioned, although it appeared that the data were incomplete. Professor Callendar, in order to arrive at a formula which should express the effect of size upon efficiency, made the assumption that, other conditions (which he precisely defined) being the same, the heat-loss and the efficiency of an engine are independent of the speed at which it is run. Though there was much to be said in favor of that assumption, it could not be said that there was direct experimental proof of it, and it did not command universal acceptance. Upon it, however, Callendar based the formula $0.757\,(1-\frac{1}{D})$ for the efficiency of an engine of cylinder diameter D (inches), whose compression ratio is such that the air-cycle efficiency is η. The formula expressed, with an accuracy which went far to show that it was substantially right, the efficiency of engines so diverse in type as those mentioned above. Nevertheless, it was pointed out in the discussion that this agreement might be fortuitous, and that before it could be accepted as final it must be shown how far and under what conditions it could be considered as applicable to other instances.

The Results of Two Years' Tests.—The author has recently completed a study of a Crossley gas engine of 40 horsepower with 11 1-2-inch cylinder running at 180 revolutions per minute. It has been possible for him in the two years during which he has been engaged in the work, to deal with certain points which the research committee could not fully investigate, or could not touch at all, in the few days which were available for their experiments. Such are the effect of mixture strength upon efficiency, the accurate measurement of heat-loss under different conditions, and the temperatures reached by the metal of the engine. He has also been able to carry out some tests on a four-cylinder Daimler engine with 3 1-2-inch cylinders running up to 1,200 revolutions per minute. More recently the opportunity for further research has been provided by the Wolseley Tool & Motor Company, who have placed at his disposal one of their well-known four-cylinder motor-car engines. The experiments on the latter engine have only been in progress for a short time, and the results are not complete, but some are available.

The author proposes, therefore, to make a comparison between the Crossley engine and the high-speed type as represented by the Daimler and Siddeley (especially the latter), in respect of efficiency, power and heat-loss. The most important aspect of heat-loss being the temperatures in the engine which it causes, it will be considered mainly in that connection. Direct experimental evidence of the relation between the temperature and heat-loss is available in the case of the Crossley engine, but not in the other case. Conclusions here are to some extent speculative.

Engines and Testing Arrangements.—The Crossley engine develops 40 horsepower on the brake in ordinary full-load working at a speed of 180 revolutions per minute. The Siddeley gives about 34 brake horsepower at a speed of 1,000 revolutions per minute, and is capable, at 1,600 revolutions, of more than 40 brake horsepower.

In testing the Siddeley engine it was direct-connected to a dynamo and measurements of brake horsepower were based on the electrical output, the dynamo losses having been accurately determined. An indicator was used, applied to one cylinder only, and indicated power was based upon the brake power. The friction loss of the engine was determined using the dynamo as a motor and reading the electrical power consumed. The petrol was contained in a graduated tank, and the rise of temperature and amount of jacket water were measured. The exhaust gases were analyzed by means of an Orsat apparatus.

The Daimler engine has cylinders 3.54 inches (90 mm) in diameter, while the stroke is 5.12 inches (130 mm), with a compression ratio of 3.85. At 1,000 revolutions it gives about 16 B. H. P. This engine was loaded with a Prony brake and the losses were measured by indicating one cylinder with the other three running idle and throttle wide open, but it was recognized that this method leads to an overestimation of the losses. So another method was devised which overcomes this, but still leaves the measurements of indicated power less accurate than those obtained electrically.

The following comparative table shows the relation between the two motors as regards dimensions and speed. The dimensions refer to a single cylinder cylinder of the Siddeley engine.

TABLE I.

	Crossley.	Siddeley.	Ratio.
Diameter (inches)	11.5	4.62	2.5
Stroke (inches)	21	5.08	....
Piston Area (square inches)	104	16.8	6.2
Stroke volume (cubic feet)	1.26	0.0495	25.5
Total cylinder volume (cubic feet)	1.495	0.0655	22.8
Compression space (cubic feet)	0.235	0.016	....
Compression ratio (r)	6.37	4.18	....
Piston speed (feet per minute)	630	850*	0.74
Piston displacement per minute (cubic feet)	113	24.7*	4.6

*At 1,000 revolutions per minute.

Methods of Determining Power Losses.—The measurements of indicated power were based on brake-power. In determining indicated power in this way, it is necessary to separately measure the engine friction, and experience has shown that it varies greatly with the temperature and lubrication of the cylinder walls. Measurement of this to be accurate must, therefore, be made when the engine is as nearly as possible in the same condition as when the brake-power and petrol consumption were determined. The procedure in the present instance was as follows: At the conclusion of the consumption test the supply of jacket water and of petrol was shut off and the engine was motored round at the exact speed which obtained in the consumption test. The power then absorbed is equal to the work done in pumping, compressing, and expanding the cold air in the cylinder plus that absorbed in friction. The first item was found in a separate experiment in which the power absorbed when motoring was measured, with the cylinders open to the air, and with the cylinders closed. It was also estimated from light spring diagrams. Both methods gave at 930 revolutions per minute about 3 horsepower, equivalent to a back-pressure of 7 1-2 pounds per square inch. Deducting this from the total, a measure of the power absorbed in friction is arrived at, which represents with reasonable certainty the power wasted by friction alone in the test.* The work absorbed in pumping when firing (about 1 horsepower) was determined from light spring diagrams and added to the friction and brake-power in order to obtain indicated power, which thus represents the positive loop of the indicator diagram. The petrol used was "Shell Motor Spirit" of density 0.721, and a large number of tests by the author and by others on petrol of various brands, and of density varying from 0.700 to 0.730, having shown that its calorific value was always within 1 per cent. or 2 per cent. of 18,900 thermal units per pound, that was assumed to be the value.

*Paper read before the Institution of Mechanical Engineers at London, Eng., Feb. 10, 1909.

NOTE.—*There was a length of several feet of shafting between the engine and dynamo which necessitated an additional bearing near the flexible coupling. The friction of this bearing is, of course, included in the measurement, and the friction of the engine is on this account rather over-estimated. But this does not affect the Indicated Power measurement. [This loss is clearly underestimated, since the power absorbed would be much greater with the pistons loaded by the force of explosions.—Ed.]

The following table shows the results of two satisfactory tests made at full load and 930 r.p.m.:

TABLE II.

	A.	B.
Work given dynamo, horsepower	28.9	29.7
Friction, horsepower	4.5	(4.5)
Pumping	1.0	1.0
Total indicated horsepower	34.4	35.2
Petrol supply, pounds p.m.	0.308	0.310
Efficiency, based on petrol	0.252	0.256
Exhaust gas analysis:		
CO_2 (per cent)	13.5	13.1
O_2	1.4	1.3
CO	0.0	0.3
H_2O (calculated)	15.6	15.9

Combustion Is Rarely Perfect.—Separate experiments indicated that combustion is rarely quite perfect; in fact, tests upon the residue in case B, exploded with electrolytic gas showed a further 0.7 per cent. of CO (reckoned on the original volume of exhaust gas). Further experimentation proved that the exhaust may contain combustible matter even with an excess of oxygen. so if we allow for this unburnt gas, the efficiency in test B, reckoned on the actual heat-supply, is over 0.26.

According to the manufacturers, 32 1-2 B.H.P. were developed at 930 r.p.m. on a petrol consumption of 0.310 pounds per minute. It seems probable that the engine losses were for some reason rather less in their test, but they can hardly have been less than 3.5 horspower (which would give a mechanical efficiency of over 90 per cent.). Taking that figure, the thermal efficiency works out at 0.26.

In experiments on the Daimler engine the efficiency was 0.255 at 900 r.p.m., reckoned on the total petrol consumption, the exhaust containing no excess oxygen or CO.

In comparing these results with the efficiency of the Crossley engine, regard must be had to the effect which mixture has upon efficiency. The author found that as the percentage of coal-gas was increased from 8.5 per cent. to 11.5 per cent., the efficiency fell from 37 per cent. to 32 per cent. In a discussion of these results it appeared that the determining factor in the efficiency of an engine of given compression ratio and size was the temperature reached in the explosion, which again depended on the heat supply per unit volume of the products of combustion. Looked at from this point of view, the Siddeley engine must be regarded as working with a high mixture strength, the air present being but little more than is just sufficient to burn the petrol. To arrive at the heat value of the mixture in the Siddeley engine, we may assume the temperature of the cylinder contents at the end of the suction stroke to be 150 deg. C. This figure is probably under-estimated.

The volume of the cylinder contents when reduced to standard conditions is 0.042 cubic feet. The heat supply per cycle per cylinder is 3.05 thermal units, equivalent to 73 thermal units per cubic foot of the mixture before explosion. After explosion there is an increase in specific volume of 5 per cent., so that the heat supplied per cubic foot of the products of explosion is 70 thermal units. In order to get an equivalent heat supply in the gas engine (with a decrease of volume of 4 per cent.), the cylinder contents before explosion must contain 11.2 per cent. of coal-gas, having a lower calorific value of 600 thermal units per cubic foot. The corresponding efficiency is 0.325, so that we can formulate the following table:

TABLE III.

	Crossley.	Siddeley.	Daimler.
Compression ratio (r)	6.37	4.18	3.85
Air cycle efficiency $\eta = 1-(1/r)^{0.4}$	0.522	0.435	0.417
Measured efficiency	0.325	0.26*	0.255
Relative efficiency	0.62	0.60	0.61
Relative efficiency (Callendar)	0.685	0.59	0.54

It will be seen that Professor Callendar's formula overestimates the efficiency of the Crossley, is about right for the Siddeley, and too low for the Daimler.

The formula gives a very close approximation to the efficiency of the large gas engine when run under the ordinary conditions. It would appear that in constructiong a formula which takes account of dimensions only, the distributing effect of mixture strength ought to be eliminated by running the engines under identical conditions in this respect. If this be done, in similar engines running at the same piston speed, the relative efficiency is more nearly independent of the dimensions than the formula would indicate.

Efficiency Varies with Speed.—If the efficiency of an engine of given compression ratio and piston speed is nearly independent of its dimensions, it follows, that in its effect upon heat-loss, the greater proportion of surface to volume in a small engine must be largely counteracted by the shortness of the time of contact between gas and metal. The efficiency of an engine will then vary with its speed to a material extent.

The fundamental postulate on which Callendar's formula was based was the independence of heat-loss and engine speed; the greater turbulence of the gases at high speeds being supposed to increase their effective conductivity to an extent sufficient to counteract the shorter time of exposure. From this the efficiency of an engine is almost independent of its speed. Professor Callendar was careful to point out that this postulate only applies to that portion of the total heat-loss which affects the efficiency, namely, the loss which occurs during and soon after ignition. This is only a fraction of the whole heat absorbed by the jackets, which includes also the heat given up by the gases during exhaust—a loss which is without effect upon the mean pressure. Measurements of the jacket loss show some increase as the speed diminishes, but this cannot be relied upon as a proof that the part of the heat-loss, which is important in the present connection, also increases in the same way.

The argument based on turbulent motion loses much force when applied to the flow of heat with the piston at rest and when the gases have had opportunity to settle. It may be doubted whether the heat loss will differ greatly from that following an explosion of the same mixture at rest in a closed vessel of the same size and shape. The author has shown that the heat-loss following an explosion varies as the square root of the time elapsed since ignition, and it seems likely that a similar law governs the loss of efficiency due to heat-loss, which would vary inversely as the square root of the speed and inversely as the square root of the linear dimensions. A careful study of this question of comparisons of efficiencies at different speeds has been made on the Daimler engine, with the following results:

TABLE IV.

Speed in R.P.M.	Efficiency.	Exhaust Gas Analysis. CO_2	O_2	CO	H_2
720	0.245	13.5	0.2	0.7	0
1,000	0.26	Not taken.			
1,200	0.275	14.0	0	0	—

In each test the mixture was such as to give maximum efficiency which corresponded to the strongest mixture consistent with complete combustion. The above table gives results at 530 r.p.m., compare the following test at 930 r.p.m.:

TABLE V.

			A	B
Speed revolutions per minute	530	535	930	930
B.H.P.	18.0	17.0	28.9	29.7
Friction	1.6	1.6	4.5	4.5
Pumping	0.6	0.6	1.0	1.0
I.H.P.	20.2	19.2	34.4	35.2
Petrol per minute (lbs.)	.219	.202	.308	.310
Analysis:—				
CO_2	13.5	13.4	13.5	13.1
O_2	0.5	1.8	1.4	1.3
CO	0.8	0.0	0.0	0.3
CO_2 after exploding residue	0.5	0.35	...	0.7
Efficiency on petrol consumption	.207	.213	.252	.256

There is no question that the efficiency at 530 revolutions is at least 10 per cent. less than at 930 revolutions.

Power from the Automobile Engineer's Viewpoint.—From the point of view of the automobile engineer, the power is of greater importance than the efficiency. Given the efficiency, the maximum power is determined by the quantity of oxygen which the engine can burn per minute. The maximum amount of explosive mixture which an engine sucking from the atmosphere

*The efficiency of the Siddeley includes an allowance for unburned gas. If this were ignored and the efficiency calculated on actual consumption of petrol it would be 0.254, and the relative efficiency would be 0.585. In the Crossley the combustion was complete, and in the Daimler the unburned gas was not determined, and no allowance was made.

can take in per stroke is equal (apart from scavenging devices, having the effect of replacing the contents of the clearance by explosive mixture) to the stroke volume reckoned at external temperature and pressure.

The ideal automobile engine would be one that took in the whole of this volume at each stroke, which is impossible because of the throttling at the valves and heat flow from the walls thus warming the mixture. From the exhaust gas analysis, it is possible to figure the quantity of air taken in and deduce from this in turn the percentage of the maximum possible amount of mixture which is actually taken in. With the average of the two tests at 930 r.p.m., this figures out at 69 per cent. In the case of the Crossley this varied from 82 1-2 to 87 per cent, while with the Siddeley the result is 83 per cent.

Difference in Heat Absorption.—In the Siddeley, however, there is a slight loss due to the fact that the pressure does not fall to the atmosphere until about 5 per cent. of the suction stroke has been completed. Allowing for this, it appears that the heat absorbed by the charge and the work done on it during suction are sufficient to warm it through 100 deg. C. against 60 deg. C. in the Crossley. The greater heat absorption in the Siddeley is perhaps due to the close proximity of the exhaust and inlet valves; a large part of the incoming stream of gas must pass over the exhaust valve, which will have a temperature of perhaps 300 deg. or 400 deg. C. Whatever the cause, however, it would appear that the reduction of this heat absorption during suction is a matter worthy of the consideration of designers. If the Siddeley and Crossley engines could be brought on to the same level in this respect the power of the former would be increased by about 15 per cent. The Daimler engine, when running at a speed of 750 r.p.m. was found to burn 0.197 pounds of petrol per 1,000 revolutions, the exhaust gases containing about 0.2 per cent. excess of O and 0.7 per cent of CO. Probably 0.19 pound per 1,000 revolutions would represent its consumption at this speed if the combustion were perfect. The corresponding supply of air is 0.0188 cubic feet per suction (reckoned at 15 deg. C.), making, together with the petrol vapor, 65 per cent. of the stroke volume. At a speed of 920 r.p.m. (when the piston speed is the same as that of the Siddeley) the ratio would not be more than 55 per cent.

In this respect, therefore, the more modern Siddeley engine shows a material improvement. This is doubtless due in part to its larger size, but the valve action is also probably better. The rise of pressure at the end of the exhaust stroke, due to the exhaust of a neighboring cylinder, was more marked in the Daimler than in the Siddeley, and it is possible that some of the exhaust gases backed through from the exhaust to the inlet pipe during the overlap of the inlet and exhaust valves. In the Siddeley engine, this overlap is reduced to a very small amount, and it is not possible that much gas can get through. Moreover, the Daimler engine did not "fill up" quite so well as the Siddeley at the end of the suction stroke. It is worthy of remark that the inlet valve of the Siddeley engine remains open until 45 deg. after the in-center.

The quantity of air taken per suction stroke falls off considerably with the speed, as is shown in the following tests of the Siddeley:

TABLE VI.

	A_1	A_2	B
Speed	530	535	930
Petrol per 1,000 revolutions (lbs)	.42	.375	.333
Exhaust Analysis:—			
CO_2	13.55	13.4	13.1
O_2	0.55	1.8	1.3
CO	0.8	0.0	0.3
CO_2 (residue)	0.5	0.35	0.7
Air per suction per cylinder	0.041	0.0395	0.0335

It appears that the air per suction stroke is about 20 per cent. greater at 530 revolutions than at 930 revolutions. The ratio of air and petrol vapor to stroke volume is 83 per cent. at the former against 69 per cent at the latter speed. This difference is ascribable to better "filling up" at the end of the suction stroke, but mostly to the lower temperature of valves and walls so that the charge is preheated less.

Tests on the Daimler engine showed an even greater variation in the volume of charge taken in, with the variation in speed:

TABLE VII.

Speed R.P.M.	Petrol Taken per 1,000 Revs.	Ratio of Air and Vapor to Stroke Volume.	Vacuum in Inlet-Pipe. (lbs. per sq. in.)
720	0.197	0.65	0.6
1,000	0.16	0.53	
1,220	0.138	0.455	

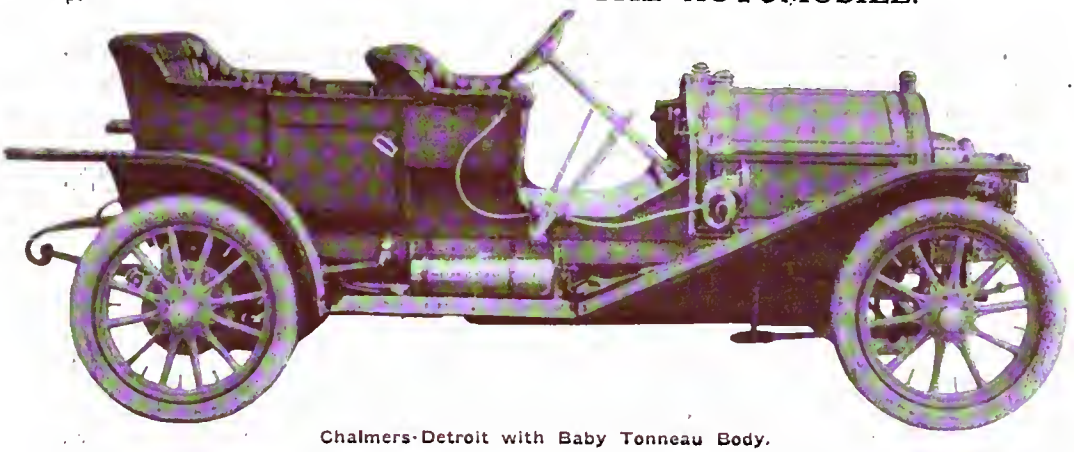
Analyses taken at 720 and 1,220 r.p.m. show that the combustion was nearly complete, and that there was no excess oxygen. At 1,000 revolutions no analysis was taken, but the petrol consumption was that corresponding to maximum efficiency, and it is certain that combustion was practically complete.

Length of Exhaust Pipe Influences the Power.—The charge volume is greatly influenced by the length of the exhaust pipes. In the tests on the Siddeley and Daimler engines which have been described, the engine exhausted through a short pipe into a box. The effect of gaseous inertia is then comparatively slight at all speeds; at 930 r.p.m. the pressure drops to atmosphere at about the middle of the exhaust stroke, and then rises again. If the exhaust pipe were considerably longer, the pressure drop would be delayed, its amount increased, and the result might be to cause a partial vacuum in the clearance space. Since the clearance volume is one-third of the stroke volume, it is obvious that a great improvement in power can be effected by filling it with mixture. The Wolseley Company informed the author that they have tried experiments of this character, and that by making use both of long inlet pipes and long separate exhaust pipes, they have increased the power of an engine by as much as 50 per cent. at high speeds. The author believes that some early tests of his own on the Daimler engine, in which considerably higher mean pressures were realized than those obtained by Mr. Morse, are to be explained by a difference in the exhaust conditions. Mr. Morse, with a short exhaust pipe opening into a box, could only obtain 15 B.H.P. at a speed of 1,000 r.p.m., the petrol consumption being 0.16 pounds per minute, whereas in the earlier tests over 17 horsepower was recorded with a petrol consumption of 0.22, some of which was probably unburned.

Heat-Flow and Its Influence.—The effects of heat-flow are of far more importance practically than its effect upon efficiency, which is comparatively slight. This is more especially true of large engines in which the stresses due to unequal expansion constitute a serious problem for the designer and are responsible for many failures. But the subject is not without its importance in the construction of small motors. The expansion stresses are not, as a rule, serious in such cases.

The factors determining the temperature of the metal at any point on the inner surface are the mean rate of heat-flow per unit area into the wall near that point, and the distance which the heat has to travel before reaching the jacket-water. The first of these factors is dependent mainly upon the *gas*—its density, temperature, and state of motion—and is but little affected by the temperature of the solid surface within the limits which are possible in practice. It is obvious that gas having a temperature of 1,500 deg. C. will lose heat at nearly the same rate to a metal surface, whether that surface be at 100 deg. or 300 deg. C. The second factor is mainly dependent upon the design and size of the engine, and on the conductivity for heat of the metal, composing the cylinder walls.

A rough approximation to the rate of heat-flow per unit of area can be obtained by dividing the mean area exposed to the hot gases into the total heat carried away by jacket-water and radiation. An estimate of this kind can, of course, only give the order of magnitude of the absolute value of the heat-flow at any point, for the distribution of the jacket loss over the different parts of the cylinder wall is not uniform, and is very imperfectly known. But it will serve as a fair basis of comparison between different engines, provided that the "mean area" used in the calculation is taken out in the same way for all. From this the temperature gradient necessary to extract the heat may be figured.



Chalmers-Detroit with Baby Tonneau Body.

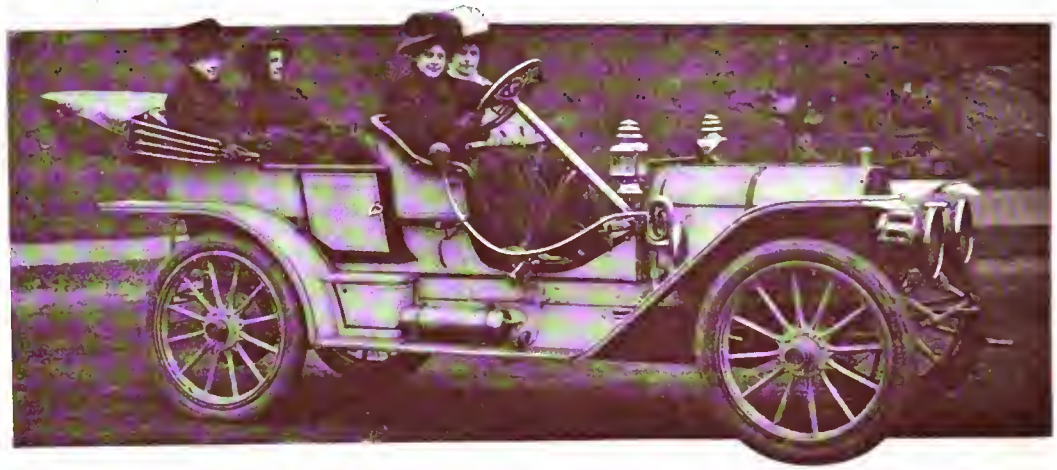
POPULARITY OF THE TOY TONNEAU.

The trend in body designs is in the direction of comfort and simplicity with a certain well-defined attempt to engender strength of the kind which makes for long life. From the rear-entrance tonneau to the seven-passenger side-entrance body was a long way, and in the judgment of numerous autoists there was a want unfilled in that the middle chamber of automobile body designing was left to its own devices, so to speak. Many autoists failed to see the logic of a body so roomy and commodious as to render it even uncomfortable, due to the fact that it is hard to stay in the seat if the foot room is so great as to make it difficult to realize a braced position under road conditions which tend to "bounce" the occupants.

Certain five-passenger bodies are so very good for the purpose that it will come as no surprise to note that the long wheelbase car-makers are now taking kindly to this class of bodies in modified form. Furthermore, "toy tonneaus" will be found on many of the best class of automobiles in which the wheelbase easily affords room for seven-passenger bodies. In the use of this construction it is possible so to locate the rear seat as to render easy-riding qualities so plausible that preference is given to the toy tonneau by autoists of discrimination.

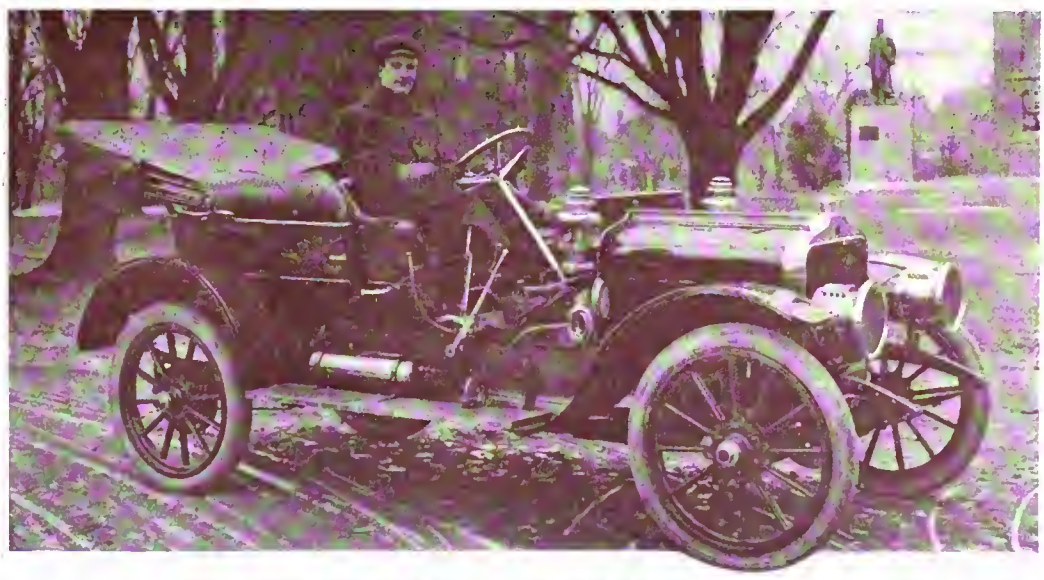
There is a difference between the conventional five-passenger body, as it is generally understood, and a modern toy tonneau, in that the five-passenger body is scarcely big enough for five; at any rate it is generally believed that three passengers in the rear seat feel as if they are living in a congested district. The toy tonneau, on the other hand, is intended to afford all the room required by two passengers—adults, in point of age and girth—and at the same time render the experience far more comfortable than it might be in a standard seven-passenger body.

Chalmers Idea of Baby Tonneau.—The illustration at the top of the page shows a Chalmers-Detroit 40-horsepower car fitted with a baby tonneau body. In this case the foot room is liberal and the side entrance is far enough to the front so that there is ample room to get in and out without brushing against the rear mud guards which as their name indicates are usually muddy. The rear seat room is also liberal although the body is intended for but five passengers.



The Haynes 1909 Model, Equipped with the Popular Toy Tonneau.

Popular Little Haynes.—The plot of the play "The Man From Home" being laid in Kokomo, Ind., the home of the Haynes car, it is particularly appropriate that both of the stars in the play should drive Haynes cars. The central illustration shows the leading lady at the wheel of her top tonneau.



Henry R. Selden, at the Wheel of 1909 Selden, with Toy Tonneau.

Selden Toy Tonneau.—The view of the Selden car allows a clear insight into the tonneau, which is seen to be divided as for two people. This gives each one a little more comfort than does the straight-backed form of upholstering, usual in tonneaus. The long wheel-base so clearly brought out in the picture, makes for easy riding qualities. A large steering stock allows turning in short radius.

MULTIPLE-SERIES PROLONGS BATTERY LIFE

By A. L. HASKELL, National Carbon Company, Cleveland, O.

THE arrangement of dry batteries as shown on the accompanying diagrams is not altogether new but until comparatively recently, it was not realized just how good an idea it was and how very useful. Another thing is that we have been able to get the dry cell to a point where deterioration is so small with the series-multiple connection. Some cells have been used six or nine months, but did not deteriorate to any extent. This enables us to get the full benefit of the series-multiple connection, which we have hitherto been unable to do. The figures explain the conditions of the tests. They were made on a four-cylinder, four-cycle engine of the automobile type at 1,700 r.p.m. We did not test every coil made, but we tested a good many, and we found that with almost every coil we tested we could get just as good results from four cells in series, in spite of the fact that people usually use five or six. We took three, four, five, six and seven cells, and tried them in series, and found in every case the length of serviceable life was almost identical, but with the three cells in series the engine would miss occasionally. With four cells the service was entirely satisfactory in every way, and you would get just as long service.

From this we have reached the conclusion that four was the most advantageous number, and so have used this number in all later tests. There are some coil makers, however, who object to these figures and recommend that their coils be used with five or six cells, and in that case we suppose the best thing to do is to take the coil maker's recommendation.

PRACTICAL TESTS—ACTUAL ENGINE SERVICE.

No.	Arrangement of cells.	Hrs. service.	Estimated miles service.	*Estimated cost per 100 miles.
146	1 set of 4 in series	20	400	25c
246	2 sets of 4 in series-multiple	70	1,400	15c
346	3 sets of 4 in series-multiple	120	2,400	11c
446	4 sets of 4 in series-multiple	170	3,400	8c

*At retail prices of batteries.

CONDITIONS UNDER WHICH TESTS WERE MADE.

1. Engine equipped with standard commercial timer and coil.
2. Average speed of running, 20 miles per hour.
3. Test stopped when engine began missing fire.
4. Cells used, Columbia igniters (size 2½ x 6 inches).
5. Continuous service.

Diagrams are Self-Explanatory.—The diagrams show how the cells are connected together in multiple series. The dry cell is not intended for very heavy service, which is the explanation of the result shown. It can stand a certain amount of current drain. If you were to subject the dry cell to a very heavy drain, hydrogen would form and the cell would go out of business. When you cannect the cells in multiple, the drain is evenly divided. In sending out these cells, the only trouble is that the average layman, unless he has a diagram, is apt to get confused and put too many cells in series, which will burn up the points and injure the vibrator points, so that we recommend sending the cells out in cases; and it is a mighty good thing to seal these cases in wax, provided you do not put it in too hot. This would set up internal action in the cell, but wax can easily be poured in at a temperature that you can put your finger in. This protects the cell and gives it a show.

In connection with the cells getting wet, each individual cell in itself is practically water-proof. Some cells are sold on the market as water-proof, but, as a matter of fact, each cell is ordinarily water-proof anyway; but if connected in series and you get them wet, it will hurt them, having them touch, whereas in single sets, it would not hurt.

*Paper read before the National Gas and Gasoline Trades Association, Chicago, Feb. 9, 1909, and the discussion of the same.

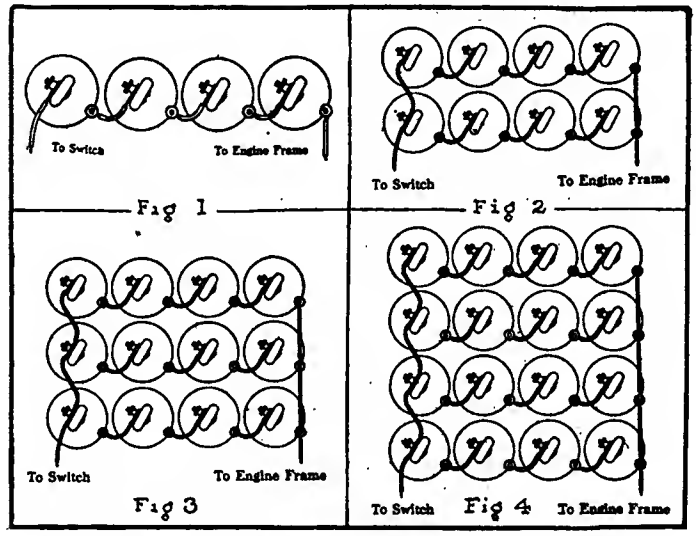
Discussion of the Paper.—President Wilson: Do I understand that connected in multiple series the drain is the same from each series?

Mr. Haskell: It is very closely the same.

President Wilson: Is not the resistance through one set of four different from some other set of four?

Mr. Haskell: It will vary a little, but in practice it does not make any difference. We have tried that, but the question arises, if you have one dead cell, whether the others are not discharging through that, and building up the voltage on that set. The large cells give very good results, and it is a question whether the efficiency of the smaller cell is greater than of the large cell. The large cell is efficient in present sizes, but whether it is more efficient than a series-multiple connection I am not prepared to say.

Deterioration Limits the Combination.—President Wilson: Could this connection be carried out ad infinitum?



Showing Batteries in Series and in Multiple-Series Relation.

Mr. Haskell: There is a limit, due to the amount of space you want to take up, and the deterioration of the cell. Any dry cell deteriorates to a certain extent, and it would not pay to carry the thing into four or five years.

President Wilson: What is the life of a dry cell under good conditions by your limit?

Mr. Haskell: That is hard to tell. We do not know what the shelf wear of batteries is.

President Wilson: How long do they become inefficient by shelf wear?

Mr. Haskell: We recommend that the battery be put into service within 60 days, in order to get efficient service.

President Wilson: On an engine, how long can they be used?

Mr. Haskell: They have been used for several years. The average is about six to nine months.

President Wilson: In a single cylinder cut-out hit-and-miss engine I find that it does not exhaust cells at all. That is, the cells go out by age limit on the ordinary engine. We have people who use them for a year and a half with one set of cells. It is not always the case, but it occurs often enough to make me think that we do not use the cells up. They simply go out by age limit. In the ordinary hit-and-miss engine the batteries will not run out in eight or nine months.

Where the Cost Ceases to Decrease.—Mr. Linn: In the last column of costs you keep on decreasing. Have you carried that out to a point where it starts to increase?

Mr. Haskell: We have carried it out as far as is practical to use them under ordinary conditions. With the reasonable coil adjustment and four sets in multiple, you get pretty fair service. In lighting in a boat last Summer we burned five lamps continuously for a month and we put ten sets of dry cells in multiples. During that time the lights had not begun to dim and we used them the rest of the season and they did not go out.

President Wilson: There would be no value in this for single-cylinder engines, which would use up one set in nine months.

Mr. Haskell: There is one more point. After the cells have been used and get down to a certain point, you can get a remarkable amount of power out of them if you connect them in series. However, it is better to connect them in series first and start with them that way. In an automobile or boat you get a reserve and are not left suddenly without any current, as might otherwise be the case.

President Wilson: In a hit-and-miss engine the coil, while it may be extravagant in amperage consumption, makes a better spark for the engine. We can take a coil that has a low amperage test and put it on an engine and it will miss. We can make no other adjustment and put on a coil with a high amperage consumption and the engine will run along.

Influence of Batteries Upon Coil Service.—Mr. Williams: The coil that apparantly shows a high consumption in current has a low resistance in winding, and if it has polarized to an extent that the voltage is low, you can put it on a coil with low voltage and it will still give some service on account of the resistance being low. It should, however, have a short timer segment and you will get better life out of the battery than you will out of a high-resistance coil.

President Wilson: With the one that would miss on the low consumption coil, we could increase the timing length and keep the engine from missing.

Mr. Williams: You can not do it when the battery is exhausted down to the low voltage. Automobile engineers make laboratory tests of coils. They put them up with dry batteries and run them continuously for so many hours to see which would run the greatest number of hours, and they would say, that is the coil for us, because the batteries last longer. They do not run them on timers with the proper length segment with each one using the coil. If they did that, they would find that the coil which used the batteries up the quickest on the long run, would give them the longest run on intermittent service, and the coil makers would have to make the coils to suit the engineers.

GOODYEAR'S NEW TIRE-MAKING MACHINE

AKRON, O., March 1.—The completion and practical operation of a tire-making machine by the Goodyear Tire & Rubber Company promises to work something of a revolution in the manufacture of pneumatic tires and to affect radically the industry so far as manual make is concerned. If the claims of the company are true the Goodyear company has the unusual good fortune to have been the first tire-making company to attain what has been the aim of the industry for years. The company now has four of these machines in operation in its new building and is preparing to install four more. Frank A. Seiberling, president of the company, is the designer.

American companies having found the machines used in France, and first used there, to be unsatisfactory, several have spent much thought and time on trying to make a better machine. It has been known for some time that the Goodrich, Diamond and Goodyear companies have been developing a machine, and the Goodrich company has had a limited number in its newest factory, but it has made no public announcement of its success. The Goodyear company has received applications from other companies for the right to use its machine in manufacturing. George M. Stadleman, secretary of the Goodyear company, in explaining the practicability of it, says:

The durability and longevity of a tire has been largely dependent on the skill and strength of the man who made it. All chance of weakness in any spot in laying layer upon layer and stretching the fabric on is now declared to be done away with by the machine's unvarying strength. To give the greatest mileage, the fabric must be stretched to an absolutely even tension over each portion of the tire, and each alternate layer of fabric must be given the same tension as those previously put on. This evenness of tension can never be given where human hands are depended upon, as tires made in the morning, when a man is fresh, will be stretched more evenly and tightly than later in the day, when his muscles are weary. Thorough tests covering the past 14 months have conclusively shown the vast superiority of machine-made tires over hand-made, in the matter particularly of blowouts, fabric breaks and separation between the plies of fabric. There is the further advantage that while by handwork a skilled workman can turn out only six or eight tires a day, and few do this well, with the machines a man of average skill can make perfect tires at the rate of 50 a day. Besides, the machines make all sizes with equal rapidity, while it takes a man longer to make the larger sizes.

THE AUTOMOBILE CALENDAR

INCREASING MOTOR POWER PER UNIT OF MASS*

By G. LUMET.

DIMINISHING the weight of the motor, or to express it technically, increasing its power per unit of mass (*puissance massique*) is the chief aim of the designer to-day. It may be well to explain at the outset just what this expression signifies. Formerly the term generally employed was specific power. The more powerful the motor was with relation to its weight, the greater was its specific power. A motor weighing 330 pounds and producing 20 horsepower had double the specific power of one weighing twice that much for the same output. But upon closer investigation, it will be seen that the expression "specific power" is not absolutely accurate in that it involves the factor of weight, which varies at different points on the earth's surface. A certain mass of lead would not have the same weight at the equator as it did at the pole. It follows, in consequence, that a motor would not have the same specific power at these two points. Hospitalier has accordingly proposed to substitute *puissance massique*, or power per unit of mass, for this expression, as the factor of mass would always have the same value.

Light Motor Responsible for the Aeroplane.

By grace of its light weight and great power the explosion motor has given us the automobile; it has made it possible to accomplish the most important progress in aviation, and, finally, it has brought about flight with the heavier-than-air machine. It would appear that the practical limit of weight reduction has long since been reached on the automobile and there is no further incentive to progress in that direction; likewise, there is but faint interest in advances of this nature on the dirigible balloon. Seemingly the only cause for the continued study of the light motor is for the benefit of the aeroplane. I believe it will be interesting to show that for the greatest good of any of the devices utilizing the power of the motor, whether on the road, in the air or on the water, every gain in weight represents progress.

But, it may be said, it will be necessary to increase the angular velocity of the motor to attain that end, and difficulties in lubrication will be encountered. The useful life of the motor will be shortened. The problems of ignition, fuel supply and cooling will all be complicated. Is the angular velocity of the motor the sole factor in the increase of power per unit of mass? I propose to show that it is not, and that for certain applications of the explosion motor it is not necessary to tend toward an increase in angular velocity. The lightening of the motor may be realized by a logical study of the other factors involved. Motors in current use, in actual running order, weigh from 17 to 22 pounds per horsepower, for units between the limits of 20 and 50 horsepower. Assume that we have a car with a 30-horsepower motor, weighing 22 pounds per horsepower, or a total of 660 pounds, and it is proposed to substitute for it one of the same power but half the weight. Should not such an advance be regarded in the light of progress?

With all the accessories now carried, such as headlights, generators or acetylene gas tanks, spare tires or wheels, tire inflators, trunks and the like, are we not traveling with considerable excess baggage, the weight of which would stand some reduction? Here we are offered a decrease of 330 pounds in the weight of the motor alone. Pneumatics are indispensable on the automobile. They must be regarded as such and conditions made as favorable as possible for their use. On the other hand, the motors of commercial vehicles must be substantially built, but a study of the conditions governing an increase in the power per unit of mass will prove that the motor may be lightened without affecting its durability. It is equally well understood that dirigible-balloon motors are already sufficiently light. Marine motors must be very durable and must also produce their rated power at a comparatively low angular velocity, as the propeller is not adaptable to high speeds. It cannot be denied that considerable interest attaches to the creation of a motor which shall be greatly lightened without affecting its durability or without increasing its angular velocity, which will permit of greatly augmenting its radius of action by allowing an increase in the amount of fuel carried through the saving in weight.

*Translated from the French of *Omnia*, by Charles B. Hayward.

Increasing the Mechanical Efficiency.

The factors influencing an increase in the mechanical efficiency of a motor are numerous. It is proposed to review these factors and we have ranged them in three groups:

1. Those having to do with the construction of the motor.
2. Those having for their effect an increase in the motor couple.
3. Those having for their effect an increase in the angular velocity.

The first class comprises those, which by a logical grouping of the members of the motor, contribute to the decrease of its weight. The Esnault-Pelterie motor (seven-cylinder, air-cooled with two-throw crankshaft and one-piece cam, 35 horsepower, weight 220 pounds or 6.2+ pounds per horsepower) is a typical example of the importance of the factor of proper grouping of the members in weight saving. A comparison of the dimensions of this motor and a standard automobile type of the same cylinder dimensions recently made showed that all the moving parts, bearings, etc., were on an equivalent scale.

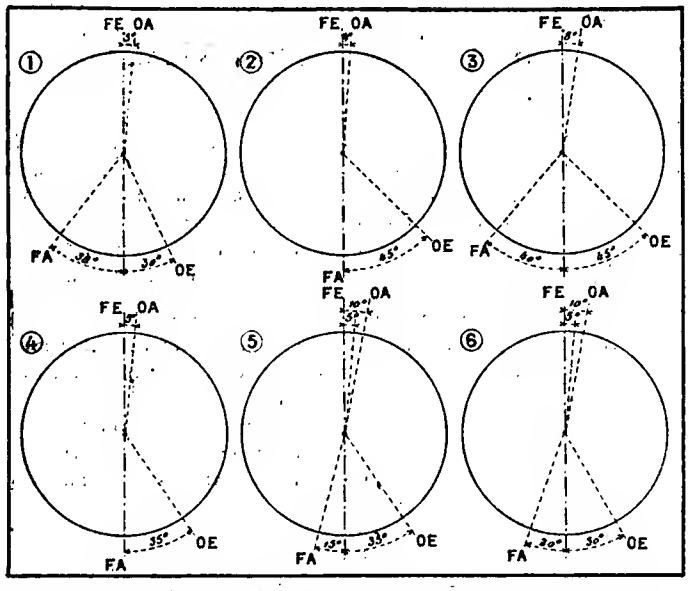
Air-cooling is an equally important factor in weight saving. In a paper on the subject prepared by M. L. Perissé for the Technical Commission of the Automobile Club of France, he has placed air-cooled motors in two classes. The first includes motors in which the general arrangement is conventional, and upon which has been superimposed a special air-cooling system, eliminating the employment of water. The Frayer-Miller and the Hautier motors are of this type. The second class is that in which a peculiar type of construction has been adopted with a view to permitting the use of air for cooling, examples of this being found in the Franklin and the Farcot motors.

Materials an Important Factor.

The choice of materials for motor construction and the lessening of the weight of moving members to decrease inertia effects are further factors, upon which a very interesting paper was recently read by M. Guillet before the Society of Civil Engineers. The following are some of his conclusions:

Important investigations are now being carried on with a view to the production of materials of high resisting qualities, this being accomplished in alloying by the addition of diverse elements, notably vanadium. It is well known that magnesium, added to aluminum in small quantities, produces an alloy of excellent resisting qualities and of a lesser density than the ordinary aluminum alloys. Why should such products not be employed in light motors? The great increase in the tensile strength and elastic limit of automobile steels now produced permit of a notable reduction in the weight of motor parts and chassis. The Germans have also recently brought out a remarkably light alloy for use in bearings, while the improvements in the direction of weight saving made in castings are really marvelous. Metallurgy has given up another of its valuable secrets to facilitate the lubrication of motor parts running at extremely high speeds, under which conditions it would be almost impossible to attain this end with the ordinary liquid lubricants. M. Guillet thinks it will be necessary to employ "auto lubricating" alloys for this purpose and that special mixtures of bronze and lead will serve best, the free lead playing the rôle of a lubricant at the excessive speeds employed.

At the present time the possibility of the employment of pistons of aluminum alloys is being investigated with the hope of being able to realize a great saving in the weight of the moving mem-



Figs. 1, 2, 3, 4, 5 and 6—Various methods of valve timing which gave increased power. OAFA, point of opening and closing inlet valves. OFFE, point of opening and closing exhaust valves.

bers, and, in consequence, a great reduction in the inertia effects. Aluminum is an excellent conductor of heat and readily parts with the heat units transmitted to it. This has an important bearing on the matter, as in a motor that has been designed to have an initial compression just short of the point of auto ignition the greater the speed the closer will this point be approached. Needless to add it will frequently be passed after running steadily for a length of time. This phenomenon arises, in part, from the fact that the piston being submitted to the heat of the explosions at very high frequency, rises in temperature to a point where auto ignition is inevitable. Moreover, the filling of the cylinder is less and less perfect at high speeds.

Consequently, if we can cool the piston the compression can be slightly increased, which will better the thermodynamic output of the motor accordingly, while by a study of the best forms of manifolds and inlet ports the more perfect filling of the combustion chamber at high speeds may be accomplished.

Augmenting the Motor Couple.

Among the conditions favorable to an increase of the motor couple must be comprised:

1. All those which have for their effect the more perfect filling of the combustion chamber, the conditions of fuel supply from the point of view of the flow of the gases, as much in the carbureter as in the manifolds, being something that should be particularly studied. Every loss in the charge is a factor tending toward the diminution of the weight of the carbureted mixture introduced. The gases should move at the lowest speed possible compatible with the proper entraining of the fuel with the air and its pulverization. This condition leads to the selection of a carbureter of large capacity.

2. In this class must be comprised those conditions favorable for ignition, both where the energy liberated by the ignition is concerned as well as the choice of the location in which is to be produced are concerned.

3. The influence of valve timing. The importance of this factor has been well demonstrated by the comparative results obtained by various settings. It is not so long ago that it was considered proper to close the inlet valve at the lower dead center. When the piston begins to return on the upstroke its linear velocity is then very low, while the speed of the gases being aspirated is, on the contrary, high and their kinetic energy is such that they continue to enter despite the piston rising against them. It must be borne in mind that the proper point for the closing of the inlet valve depends somewhat on the speed of the flow of the gases, and in consequence, upon the characteristics of the motor and the sections, length and form of the manifolds.

Some Different Valve Settings Compared.

The figures reproduced herewith serve to illustrate some different standards of valve timing employed on a number of motors. The letters *O A, F A,* indicate the points of opening and closing the inlet valve, while the letters *O F, F E,* indicate the opening and closing of the exhaust valve. Fig. 1 represents the timing of a motor of 3.9-inch bore (100 millimeters), which, according to the formula of the *Commission Technique* of the Automobile Club of France, should produce 33.88 horsepower, and which, in reality, showed 40.28 horsepower. Figs. 2 and 3 are modified standards of timing the same motor. With the first (Fig. 2) it showed an increase that brought its total up to 50 horsepower, and with the second (Fig. 3) an output of 56.5 horsepower. Figs. 4, 5 and 6 represent successive variations in the regulation of a motor which gave 28.2 horsepower with the first and 33 horsepower with the third.

An increase in the compression is a favorable element in the augmentation of the motor couple, but the value of its effect on the increase of power per unit of mass is doubted by some authorities. The point of opening the exhaust valve plays an important part in the increase of compression, in that these two elements are interconnected in their influence on the increase of the angular velocity. If the compression be increased within the limits of auto ignition, of course, it will be necessary to advance the point of exhaust-valve opening in order to increase the angular velocity. In this manner one part of the cycle may be bettered, but another is sacrificed.

HARMONIOUS RELATIONS SHOULD OBTAIN

IF the design is right, and the materials are as good as they ought to be (theoretically), then it is assured that any process which will maintain the torque at a maximum and allow of increasing the speed to the mechanical limit, from the gear ratio point of view, will end in the maximum possible result from the point of view of the reciprocating motor under conditions not including a change in the fuel. It is easy enough to handle speed up to at least 3,000 r.p.m., and the process resolves itself into one which will realize torque on a stable basis as a result. The maximum torque will be the product of efforts in the directions as follows:

(a) By the elimination of mechanical losses:
(b) through the utilization of the most suitable mixtures;
(c) if the timing is correct;
(d) assuming the scavenging is well done;
(e) through the use of an energetic ignition system;
(f) effective cooling at the most advantageous temperature;
(g) the maximum volume of the charge, or mixture;
(h) the most advantageous compression.

The mechanical means of arriving at these desirable conditions is a matter that has no place in this article. That a motor to do the work, as here indicated, must be of a harmonious design, goes without saying; moreover, it is not enough to say the valves must be large. It is not necessarily a fact since they may be relatively small, and by opening them at the propitious instant, and holding them open long, the relatively small valves may be even superior. If valves are large, then it is to note that they will be more prone to warp, and warping means loss of compression. In a dozen ways there are mechanical reasons why a motor may perform below the requirements, from the point of view of holding to a maximum torque, and preventing the torque from falling away as the speed increases.

Letters Interesting and Instructive

FREMONT IMPACT TEST FOR MATERIALS.

Editor THE AUTOMOBILE:

[1,769.]—In view of some of the articles in THE AUTOMOBILE in which the question of the qualities of materials are discussed and the tests for impact are given, would it not be a good idea to explain the nature of the "Fremont" test for illustration? This is the impact test most used, perhaps. I, for one, do not well understand the nature of the test, although I do appreciate the fact that the material is shocked to rupture. L. E. D.

Oakland, Cal.

In this test for impact ability of materials the "proof" is machined to some predetermined size. For illustration:

(a) Length, 35 millimeters;

(b) Beam width, 10 millimeters;

(c) Beam depth, 8 millimeters;

(d) Notched at the middle, on the under side, to a depth of 1 millimeter, thus making the depth of the bar 7 millimeters at the notch. The bar, so finished, is set upon supports, so that the unsupported distance is 30 millimeters, with the notch on the under side, midway between the supports.

(e) In this position the test-piece is struck one blow with a "tup," designed to afford the requisite energy to fracture the specimen. In a word, considering a given weight of the "tup," the distance of the fall is so regulated as to gather enough energy to fracture the specimen.

(f) The residual energy in the weight (the energy in excess of the exact amount required to fracture the test-piece) is measured by allowing the weight and the fractured test-piece to fall on a steel plate, the latter being in the same plane, below, resting upon springs. The pressure on the springs produces a deflection, and, in view of the fact that the springs are carefully calibrated, they serve as a spring balance, and by the use of a suitably devised lever the energy absorbed by the springs is taken note of.

(g) The energy represented by the fracture of the test-piece is the difference between the prime impact energy of the "tup," deducted from its mass and distance of fall, and the residual energy, as shown by the interpretation of the spring plate performance.

(h) In this way the impact resisting properties of the steel are arrived at within about 1-75, considering the use of fairly tough steel. On the other hand, it is fair to say that the actual accuracy of the test is dependent largely upon the quality and condition of the steel.

There are divers ways of testing for impact and each has advantages as the conditions change. This phase of the subject is so broad and so important that it will not be possible to interject here a comprehensive discussion of its phases.

TAKES TIME TO GROW A DEPTH OF CARBON.

Editor THE AUTOMOBILE:

[1,770.]—Please tell me if a piece of cold rolled steel can be case-hardened by any process in a few minutes. As I understand it, the carbon content in the "normal" steel is below 10 points, and since case-hardened steel, considering the shell, has a carbon content of about 90 to 110 points, I do not see how any quick process will result in any great depth of the hard shell HARDENER.

Philadelphia, Pa.

There are hundreds of receipts said to be satisfactory for this purpose, but few have been accepted by metallurgists. Authentic information on the subject seems to lead to the conclusions as follows:

(a) The time depends upon the composition of the cement;

(b) The heat (sensible) influences the situation very much; 900 degrees centigrade is a safe temperature;

(c) For a penetration of 10 to 12 thousandths of an inch, the time required, considering the above temperature, will be 1 hour, after the parts reach the degree of heat stated. In 10 hours the penetration will be about 5 times what it will be in 1 hour.

RELATION OF AIR TO GASOLINE MIXTURES.

Editor THE AUTOMOBILE:

[1,771.]—I wish to determine the volume of liquid gasoline required to produce a given volume of vapor, and the ratio of gasoline vapor and air for the best explosive mixture. Can you give me the above information? CHANDLER PRINCE.

Ann Arbor, Mich.

Gasoline is a somewhat uncertain mechanical mixture of several hydrocarbon (fractional) distillates, in which the compound "hexane" is supposed to be the major portion. This compound answers to the formula $C_6 H_{14}$, the products of combustion of which will be $C O_2 + C O + H_2 O$, in which C O will not be found if the combustion is complete. A final expression of complete combustion will be as follows:

$$2 C_6 H_{14} + 19 O_2 = 12 C O_2 + 14 H_2 O.$$

Taking into account the atomic weight of the elements, the volume of air required in the complete combustion of 1 pound of hexane may be set down as follows—atomic weight of the elements involved:

Carbon (C)	12
Hydrogen (H)	1
Oxygen (O)	16

The molecular weight of $C_6 H_{14} = 6 \times 12 + 14 \times 1 = 86$; the required oxygen will weigh (molecular) $19 \times 16 = 304$; the ratio of the compound, hexane, then, to the combining oxygen will be

$$\text{Ratio} = \frac{304}{86} = 3.54, \text{ nearly.}$$

Considering 1 pound of hexane, the weight of oxygen required for its complete combustion will be equal to the ratio as above given, i.e., 3.54 pounds, nearly.

Since the oxygen is taken from the air, it is necessary to consider dry air in the attempt to determine as to the weight of the same. This air, under a pressure of 1 atmosphere, and at a temperature of 60 degrees Fahrenheit contains 0.23 pounds of oxygen, hence the required air $= \frac{3.54}{.23} = 15.39$, in pounds.

BRIDGE-CONSTRUCTED SOLID TIRES.

Editor THE AUTOMOBILE:

[1,772.]—Please give opinion of "bridge constructed" solid tires. Also state, if possible, actual and comparative values, power loss in 36 by 4 airless and ordinary pneumatic, when new and after 5,000 miles, if each is supporting 1,000 pounds. Will not the blocks of rubber crush in time and thus cause the tire to ride harder and harder and consume more and more power? SUBSCRIBER.

Lafayette, Ind.

The data asked for cannot be given, as we have never heard of any tests of this nature having been made. When you come to think of it, this is rather surprising, too. Why don't you make these tests yourself, and thus answer your own questions? The most that we can say in this connection is that the records of both solid and pneumatic tires as made in actual service speak for themselves. The rubber blocks should not crush, if the maker's specified loads are not exceeded° that is, if you do not load the tire beyond the weight for which it was designed.

WEIGHT VERY UNDESIRABLE IN AUTOMOBILES.

Editor THE AUTOMOBILE:

[1,773.]—Since in marine motor boat work the noise of the exhaust is silenced by copious applications of water in the exhaust manifold, back of the motor, with a considerable length of pipe between the point at which the water enters and the muffler, would not water be good to use in automobiles for the same purpose? A. B. WAITE.

Boston, Mass.

If account be taken of the weight of water used in cooling systems, in automobiles, and considering the objections raised,

despite the presence of only about 50 pounds of water in the average cooling system, it will be quite evident that a water silencer or muffler, which would weigh a considerable amount, cannot be recommended despite the fact that silent performance would be a feature. In marine mufflers the amount of water used is vastly more than would find a place in an automobile as they are constructed at the present time. Water weighs 8.33 pounds per gallon, and 42 gallons, a barrel full, would not last long enough to give satisfaction.

LEVER ADVANTAGE AND GEAR RATIO ENTWINED.

Editor THE AUTOMOBILE:

[1,774.]—All other factors remaining the same, what is the difference in percentage involving a car geared 3 to 1, or 3½ to 1, taking into account (a) power and (b) speed?

What are the names and distinguishing features of the several quick detachable rims, as distinguished from clinchers?

What is the difference between high and low tension magnetos in reference to (a) use of coils, (b) use of timer or distributor, (c) intensity of spark, (d) use of one set of spark-plugs in connection with battery, coil and timer system? SUBSCRIBER.

Walden, N. Y.

Considering the gear ratio, it is proper to say (a) the power of the motor is independent of the gear ratio, but if the gear ratio is not suited to the needs the motor will not be in a position to deliver maximum power; (b) if the best power speed of a motor is, say, 900 revolutions per minute and the gear ratio is 3 to 1, the road wheels will have to run at 300 revolutions per minute. But if the motor has not the power requisite for the task, the speed of the motor will fall off and the scheme will be thwarted. In this case it will be proper to consider a gear ratio such as will afford the desired harmony, and perhaps 3 1-2 to 1 would be suitable. In such an event the motor at 900 revolutions per minute would drive the road wheels at 257 revolutions per minute, in round numbers. In this case it is difficult to see how any question of percentage relation can be of the least value, since it is mainly a matter of fixing upon the one right gear ratio.

The names of makers of the several rims will be found in THE AUTOMOBILE TRADE DIRECTORY; names of makers cannot be quoted in these columns.

The differences in magnetos were well discussed in THE AUTOMOBILE of Feb. 25 by J. A. Williams. (See Page 245.)

GEAR RATIO FOR A SPEED CAR.

Editor THE AUTOMOBILE:

[1,775.]—Please state what will be a good gear ratio for a speed car; taking into account a three-speed selective transmission.

Trenton, N. J. GO IT SOME.

In speed cars it is the practice to consider that the gear-set should afford three speeds ahead as follows: (a) accelerating, (b) hill climbing, (c) speeding, and (d) reverse. The following is an example of what proved to be good practice in this zone of automobile activity:

MOTOR AT 1,000 REVOLUTIONS PER MINUTE.

Accelerating, 23 miles per hour of the car;

Hill-climbing, 69 miles per hour of the car;

Speeding, 93 miles per hour of the car;

Reverse, 13 miles per hour of the car.

The above is a case from actual practice considering a car with a motor of sufficient power to make the speeds as given.

A LITTLE SMOKE IS QUITE A GOOD SIGN.

Editor THE AUTOMOBILE:

[1,776.]—My car has a good oiling system and I get excellent service from it, excepting that I borrow trouble about the oiling question. An expert told me to oil until smoke shows up at the exhaust. I have been told also that the excess lubrication which is indicated by smoke will result in a carbon deposit on the combustion chamber walls. What would you advise me to do? T. B. DELMAS.

Columbus, O.

The two horns of the dilemma are there. When the car first starts out in the morning there is no question but that a little smoke will prove beneficial indirectly, proving that lubrication is proceeding. Always be sure that all the bearings will be oiled; profuse oiling is superior to chance work. Do not allow the motor to smoke all the time, or, as you say, excess lubricating oil will result in carbon deposit.

WATER CIRCULATION DEFECTIVE.

Editor THE AUTOMOBILE:

[1,777.]—I have a double-opposed motor, and during the first season it ran quite well. It has a tubular radiator and a gear pump, also a coil and battery sparking equipment, which details I deem it expedient to mention, in connection with the fact that when I run the car for a while and then attempt to shut the motor down by cutting off the spark it (the motor) continues to run. Please tell me why. READER.

Chicago.

Pre-ignition in this case is due to the presence in the cylinders of some deposit, and that the jacket walls are incrusted to some extent is probably true. In the meantime the gear pump is probably in a leaky condition and the amount of cooling water is less than was formerly circulated.

USE BEESWAX ON THE CLINCHER RIMS.

Editor THE AUTOMOBILE:

[1,778.]—The rims of my old car do not keep free from rust, even though I do clean them off and apply black enamel. What can you do to help me out? H. D. L.

Erie, Pa.

Clean the rims off as well as possible and get rid of all the rust which will come off by scraping through the liberal use of sandpaper. Then apply a coat of bees-wax. It will have to be heated by a blow-torch or otherwise. The bees-wax will prevent the further formation of rust, because it combines with iron-rust, and the compound clings to the surface of the metal so that the air is thereafter excluded from the surface. Bees-wax will not damage the tires.

WANTS TO BE ABLE TO TURN IN NARROW STREET.

Editor THE AUTOMOBILE:

[1,779.]—I have in mind the designing of a town car, and there are points which I do not well understand, as, for example, the question of the length of the wheelbase as related to the radius of turning. Will you please state in an early issue of THE AUTOMOBILE the wheelbase length which will enable a car to turn around in a narrow street, say, with a clear space between curbs of 36 feet?

New York City. R. J. W.

If the front road wheels can be "canted" 36 degrees to each side of the center the car may have a wheelbase of 102 inches—to be a little precise—but with 100 inches wheelbase there will be a little spare room, which will be an advantage.

BATTERY IS RUN DOWN COMPLETELY.

Editor THE AUTOMOBILE:

[1,780.]—My car (a one-lunger) runs for a few hundred yards and then the cylinder misses, until finally the motor stops. The spark at the gap is there when I shut down for a time. What can you make of it? G. L. SANDERS.

Charleston, S. C.

The battery is run down, and if you use dry cells the chances are that what you need is a new set. In case you use a storage battery it will have to be recharged if it is in good order; in case it is not in good order it should be put in the hands of a repairman of competence with a view to rebuilding it.

FRANKLIN CYLINDER SIZE WRONGLY QUOTED.

Editor THE AUTOMOBILE:

[1,781.]—In your issue of February 4 (Letter No. 1,730, "Discrepancy in Horsepower Ratings"), a subscriber to your paper lists the Franklin engine as follows: 4-inch bore, 4½-inch stroke, 18 horsepower. Your subscriber is in error in this by reason of the fact that the bore for our 18-horsepower engine is 3⅝-inch, stroke 4-inch.

We call this to your attention owing to the fact that your subscriber's arguments are based especially on the size of the cylinders in our engine. As he is evidently laboring under a misapprehension, he had better be straightened out in the matter.

Syracuse, N. Y. H. H. FRANKLIN MFG. CO.

A New York State Road near Albany.

ROADS BUILDING NOW COMMANDS NATIONAL ATTENTION

BEAUMONT, TEXAS, has a population of 30,000, and, according to Albert Phenis, a special correspondent of the *Manufacturers' Record,* it owes its prosperity to the attention it has paid to the development of its roadways. There is a movement on foot to secure a good road from New Orleans to San Antonio, a straightaway distance of some 1,200 miles. John W. Gates, who, at his Port Arthur home, is devoting much of his energies, his time and his money to the development of this section of Texas, is an enthusiastic helper in this work. Much preliminary work has been done already, and it is reported that the active co-operation of all the county and parish authorities in Texas and Louisiana is almost instantly secured when once the advantages of good roads are presented to them. The counties and parishes that are not in the movement readily realize the disadvantage they would be under if they refrained from joining in a movement their neighbors have undertaken, and so it is largely a matter merely of passing the word along and securing thus the co-operation of county after county in the work.

The Beaumont and Jefferson County Good-Roads Association has been extremely helpful as well, in getting the work of good-road development followed out along economical and scientific lines. The engineer of the association gets up plans for the new roads on scientific plans, providing for drainage and all other requirements, and in this manner it has been possible to secure the maximum amount of benefit for the minimum of cost. The statement is made, that in the construction of the roads in this county, since the first costly experiments, over $600,000 has been spent. Incidental to this development of good roads, there has been a remarkable increase in the number of automobiles in use in Beaumont. Statistics are to the effect that not less than 150 machines are owned here now, with a number of new ones ordered and on the way.

Beaumont has steadily grown and has become a substantial, well-built and very prosperous city. The values of real estate have held their own at all times, with a gradual and maintained advance. There has been a development of farm property as well, with a material enhancement in values, particularly along the improved roadways. The multiform advantages of the good roads of this place are so evident and so universally recognized that every citizen and taxpayer is an enthusiastic advocate of the proposition, and the Beaumont and Jefferson County idea is finding favor everywhere around.

So a good road from New Orleans to San Antonio is not so far from actual realization. New Orleans people have already inaugurated a good-roads movement that has borne fruit in at least one stretch of good road to the East. Atlanta is active in behalf of a Washington to Atlanta highway, and with the increasing number of Winter tourists who visit the coast country between Mobile and New Orleans, it can scarcely be very long before all the gaps are filled and a fine highway provided between San Antonio and the national capital—in fact, between the Far South and all the North Atlantic seaboard.

JACKSONVILLE-FERNANDINA ROAD PROPOSED.

FERNANDINA, FLA., March 1.—Backed by a strong favorable public sentiment, the proposal of the Jacksonville Automobile Club and the local Board of Trade to have a road built from this city to the metropolis of Florida, is taking tangible form, and it is probable that, within a very short time, actual work upon it will be begun. The movement is of prime importance to the people of this city, as well as to automobilists of Jacksonville and those who annually tour in this State.

The plans call for a hard highway down the center of Amelia Island, upon which this city is located, the building of an inexpensive draw-bridge, with its necessary piling approaches, and connections with existing good roads in Duval County leading to Jacksonville. The cost has been found to be very slight in proportion to the need for it, and through the combined effort of all those who are interested the proposition will be pushed. There has been nothing but favorable comment upon the project, inasmuch as it will not only open a fine route to this city for automobilists, but it will also give a road for truck farmers to take their goods to Jacksonville, as well as to bring them here, opening up for cultivation a great deal of now inaccessible country. With its natural seaport facilities, automobiles from the north can be unloaded here and much time saved in shipment.

IMPORTANT SOUTHERN BRIDGE COMPLETED.

SAVANNAH, GA., March 1.—With the completion of the King's Ferry bridge over the Ogeechee River, about 15 miles from this city, one of the most important links in the route from this city to Jacksonville has been opened to travel, and it will be but a comparatively short time before autoists can make the run between these two cities in ease. On Washington's Birthday the bridge was opened to travel with appropriate ceremonies, and in the evening a dinner was held in honor of the occasion, at which a number of prominent men spoke, among them being ex-Governor Robert B. Glenn of North Carolina, ex-Governor Albinus Nance of Nebraska and F. C. Battey, president of the Savannah Automobile Club.

The Jacksonville Automobile Club combined with the local organization in the festivities. The bridge itself was built by the county commissioners, through the work of the convicts who did such good work in laying out the course for the Grand Prize race. They were used also in building the roads to the bridge, and Bryan County, on the other side of the river, will use convicts in extending the route southward to the Florida line. Already this is a popular touring route and will become more so, for the roads run through some of the most distinctive and beautiful scenery in the south and the surface is fine.

BOOSTING TRANS-PENNSYLVANIA ROAD.

PHILADELPHIA, March 1.—Last Saturday saw the Philadelphia-Pittsburg highway given a good boost when upward of one-hundred delegates of good roads associations met in the Capitol at Harrisburg and formed a permanent organization under the title of "Forbes State Road Association," with Senator W. C. Muller, of Bedford, as president, and J. A. Strite, of Chambersburg, secretary. No special route was advocated, it being the sense of the meeting that all hands should pull together for the road, leaving the selection of a route to be determined later by a commission. The name "Forbes" was adopted in honor of the general of that name who built the first military road across Pennsylvania between the two cities. In view of Governor Stuart's efforts in helping along the project a resolution recommending that the new road be called the "Stuart State Highway" was unanimously adopted.

"Farmer" Creasy, who is not at all enthusiastic over the Philadelphia-Pittsburg road, at last Tuesday night's session of the Legislature, introduced a resolution demanding an investigation of the entire highway department for having allowed contractors to collect $345,147.55 as "extras" over and above their contract prices for building 352.2 miles of roads during 1907. If this resolution is favorably acted upon by the Legislature, it will in all likelihood postpone all good roads legislation for many weeks, if not head it off entirely for the present session.

NEW JERSEY'S OCEAN BOULEVARD.

TRENTON, N. J., March 1.—The Senate Committee on Agriculture to-day gave a hearing upon the scheme to build an ocean boulevard, extending from Atlantic Highlands to Cape May, connecting the same with the county seats of the various counties of the State by State roads. It carries no State appropriation and, it is believed, will be favorably reported. The bill was supported by a great many influential men, who explained that the counties would be expected to bear two-thirds of the expense and the State one-third at a later time. The plan was opposed by a number of men from interior counties who claimed that their constituents would receive no benefit from it, would have their taxes increased accordingly, and that the road would be for a certain class rather than for the whole State.

GOOD ROADS MOVEMENT IN MAINE.

PORTLAND, ME., March 1.—The prospect of a State highway from Kittery, at the southern point of this State to Bangor, a dream of autoists and others for some time, will probably become more realistic in the near future, if the work now progressing upon roads in this State continues, and there is every likelihood that it will. The good roads movement has taken a firm hold in all parts of the commonwealth and tourists who come here this summer will readily see the improvement. Roads are being built in all sections in line with a plan to have the various towns construct roads that will join in continuous lines when completed.

INDIANAPOLIS SPEEDWAY PLANS CHANGED.

INDIANAPOLIS, IND., March 1.—An important change has just been made in the plans for the track of the Indianapolis Motor Speedway in the decision to make the outer track two and one-half miles long and the inside loop track the same length, the original plans calling for an outer track of two miles while the inner track was to be three miles. It is believed that with the change to be made, greater speed can be attained. Several events of importance have already been scheduled for the track. Probably the first will be the run by a National stripped stock car of 1,000 miles a day for ten days.

Another event scheduled is the annual meet of the Federation of American Motorcyclists, to be held here some time in June. The stakes for the track have all been set and the actual work of making it will begin within a few days.

NEW ENGLAND 1909 BLUE BOOK OUT.

First of the 1909 series of "Official Automobile Blue Books," issued by the Class Journal Company, is out this week, the volume covering broadly the New England States, with portions of the Hudson Valley and extension routes into the Canadian provinces, and to the principal cities.

The 1909 edition consists of 792 pages of closely compiled matter, of which a large proportion has been written and mapped new during the past year. This is especially true of Vermont, the principal routes of which were covered almost entirely by the "Blue Book" car, very recently.

Among the new routes included in this volume are Burlington to Montreal and reverse of same, Montreal to Burlington. These routes have been the subject of a great deal of inquiry from tourists for several years, and now for the first time specific running directions and odometer measurements are available in their entirety, formerly given approximately.

A valuable feature has been added to the new edition in the form of general maps covering the entire territory, showing the relation of one route to another and the territory at large, including all important cities and most towns. To facilitate reference the general maps have been keyed by letters and figures. Each town or city in the "Index of Places" is supplied with a letter and a figure, the use of which will save time and trouble in locating the points desired.

Copies of the New England book will be on sale at the Boston show during the coming week, and orders for same can be filled by the hotels and garages through New England and the Hudson Valley, as well as by leading booksellers; or they can be ordered direct from the publishers, the Class Journal Company, 231 West Thirty-ninth street, New York. Other volumes, covering other districts, brought to date, are now at press.

A Friend in Need!

Tramp (to clerical motorist whose spanner has just slipped, at the expense of a barked knuckle): Beg pardin, gov'ner, but can I say anything for yer?—From "The Car."

WHAT THE LAW-MAKERS ARE FRAMING THESE DAYS

HORSEPOWER RATES IN VERMONT.

MONTPELIER, VT., March 1.—"In a spirit of malicious glee," according to the opponents of the measure, the Legislature of this State recently passed a series of new motor vehicle laws, embodying a number of features seen in the present trend of legislation in a number of States, a license fee based upon the horsepower rating, reciprocity with States showing the same courtesy to Vermont autoists, and a maximum speed limit of twenty-five miles per hour.

Three statutes were used in amending the previous law, now covering nearly all points, though it was opposed by a majority of the automobile users, and put through largely by opponents of auto touring. The fee is now one dollar for every horsepower of the machine, with a provision placing a bonus on the keeping of the same car from year to year, the second year the fee being reduced one quarter and the third and each succeeding year by one-half of the first sum. This applies, in the enforcement of the new act, to all cars licensed in 1907 or 1908 and to autoists from other States, who may register this year, a car which has been registered previously in other States.

The new law exempts the car from any other tax, allows one registered after August 1 a discount of 50 per cent., and if sold provides that the registry may be passed along to the new owner for a consideration of one dollar. **The reciprocity section allows autoists from States which grant a similar privilege to those of Vermont in touring,** to tour in this State for not more than ten days without registering. For a presence in the State of from ten to sixty days there will be a charge of $3 for cars of 20 horsepower or less, $6 for those between 20 and 40 horsepower, and $10 for cars of over 40-horsepower. For a period of more than 60 days the car would be amenable to the State law.

In considering speed the statute says: "No automobile or motor vehicle shall be operated on the public highway in a careless or negligent manner," recognizing 25 miles per hour in the open country as the dividing line between careful and careless running, ten miles per hour in cities or incorporated villages, and permitting towns to regulate the machines in their own limits.

SEVERAL MEASURES PENDING IN DELAWARE.

WILMINGTON, DEL., March 1.—Automobilists all over the State are keeping their eyes on Dover until after the present session of the Legislature, as notices have been given of a number of new bills proposed to regulate the use of motor vehicles. It is hardly likely that all of these bills will come in, but some of them are looked for and will probably be acted upon.

The proposed measures come from different sources and have different objects. One, prompted by some of the car owners of the State, seeks a reduction in the license fee; another, which was sent down by farmers of Brandywine Hundred, wants a tax imposed for the use of tires with chains, on the ground that the chains damage the roads, while the farmers also seek to reduce the speed. Another bill is to remodel the automobile regulations.

The Delaware Automobile Association has decided to fight the bill which passed the House of Representatives a few days ago, taxing automobiles as personal property. This decision was held at the last meeting of the association, when several other subjects were also considered. The association is also interested in a proposition to have another ferry between Wilmington and Penn's Grove, N. J., for carrying automobiles.

ONE DOLLAR PER HORSEPOWER TAX.

MINNEAPOLIS, MINN., March 1.—After weeks of hard work and anxiety, the leading motor enthusiasts of this State are now feeling easier about the new automobile bill which finally has the unqualified endorsement of all of the nineteen clubs affiliated with the State organization. The bill provides for a tax of $1 per horsepower in lieu of all personal taxes on the machines, and, besides several other desirable features, it directs that all funds accruing from this taxation shall be used by the State Highway Commission in the good roads work of the entire State. This will annually add between $150,000 and $200,000 to the good roads funds now available.

The bill was introduced in both Senate and House and was referred to the committee on legislation. At this point two clubs which, it developed later, had given the matter hasty consideration, communicated with the Senate committee speaking against the bill. The result was that the committee postponed action indefinitely until the bodies of the State association were unanimous in supporting the measure. By quick and effective influence the objections of these two clubs were removed and there is now every chance in the world that the matter will be reported favorably out of the committee and action secured soon.

REAL RECIPROCITY WANTED IN JERSEY.

NEWARK, N. J., March 1.—Real reciprocity, the kind which permits an autoist of any State granting a similar privilege to those of this State, to tour in New Jersey without first taking out a license, is what is now wanted according to the direction the opinion in this city has taken. The new automobile bill, which would alleviate to a great extent the obnoxious statute now upon the books, has had its second reading in the State Assembly, introduced by Austen Colgate, of East Orange, and it is considered as likely that it will pass the Senate when it reaches that body, and soon replace the present law.

This bill, however, would require non-resident autoists to pay $1 for a license which would allow them to tour in this State temporarily and this does not meet with favor here. If the uniform law is adopted in New York and Pennsylvania the shoe would be on another foot, for then Jersey automobilists would be required to take out licenses in those States unless the present bill pending is so changed as to give to all non-resident members free rights here. Real reciprocity is what is wanted, whether it is given at once in return or not.

NO SPEED LIMIT IN WISCONSIN.

MILWAUKEE, WIS., March 1.—If the Wisconsin Legislature acts favorably upon a new law which has been introduced by Senator E. E. Page, of Milwaukee, automobilists of this State will have a law which does not mention any definite speed limit, using the more logical term of reasonable speed, wiping out the present statute, and giving one devoid of regulating features. It would also take away from State control such highways as are privately owned, and would forbid the enactment by any city or local authorities of conflicting regulations, thus making the law uniform throughout the State.

Still another bill has been introduced which is aimed at "joy-riding," making it a misdemeanor, punishable by fine of not more than $100 or thirty days in jail, for any person to drive an automobile unless the owner is riding in it or has given consent to its use. It is hoped that this will end a nulsance.

What the Clubs are Doing These Days

HARRISBURG CLUB WRITES MR. HOWER.

HARRISBURG, PA., March 1.—Inasmuch as many sundry reports have come to the capital of the Keystone State, and to its Motor Club, of the effect upon automobile contests, of the appointment of Frank B. Hower, of Buffalo, as chairman of the Contest Board of the American Automobile Association, although no official notification of this has been received, the Motor Club has decided to proceed unmolested to perfect the arrangements for its third annual endurance run.

The dates have been fixed—May 3 to 6, inclusive—and a route decided upon which will give those who enter not only a good run for the trophy, but also a beautiful and pleasant tour over all conditions of roads. Covering about 175 miles each day, a total of 700 will be reached, making the event one of the most important ever held in this section of the country. Leaving this city upon the day of the start, the cars will run via Gettysburg, Hagerstown, Harpers Ferry and Frederick to Washington, D. C. On the second day they will return to this city via Baltimore, Westminster, York, and Lancaster. The route for the third day will be to Scranton, following the Susquehanna River and passing through a number of towns, including Wilkes-Barre. The final run will be another return to Harrisburg, first crossing the Pocono Mountains and down through Stroudsburg, Delaware Water Gap, Easton, Allentown and Reading.

There has never been scheduled a better route in the East than this one, and active preparations for the contest have been started. The list of technical penalties will be made by David Beecroft, editor of *Motor Age*, chairman of the technical committee.

At the last meeting to consider the matter a thorough discussion took place regarding the attitude of the club toward the chairman of the Contest Board of the A. A. A. A motion to hold a contest without any reference to Mr. Hower's committee was laid on the table, as was a motion to apply for a sanction to the Automobile Club of America. Finally the following letter to Mr. Hower was agreed upon:

Dear Sir:—It has been stated in the newspapers, although we have received no official notification to that effect, that your committee wishes to extend its authority and sanctioning power over all local reliability contests. The statement has also been published that you are planning to draw up, or have drawn up, a set of rules for the use of local committees.

If we had your rules before us, we would be very glad to consider them carefully and adopt from them such suggestions as might be thought applicable. Not having had any communciation from you, we are compelled to rely upon our own resources, as in previous years.

We therefore beg to inform you that we have printed our entry blanks, decided definitely upon our rules, route, etc., and selected as our officials the same gentlemen who have acted in our previous contests. In conclusion we would say that, on receipt of the proper official notification, we are quite willing to pay to your committee the sum of twenty-five dollars, the sanction fee as quoted in the newspapers.

Yours respectfully,

CONTEST COMMITTEE,
Motor Club of Harrisburg.

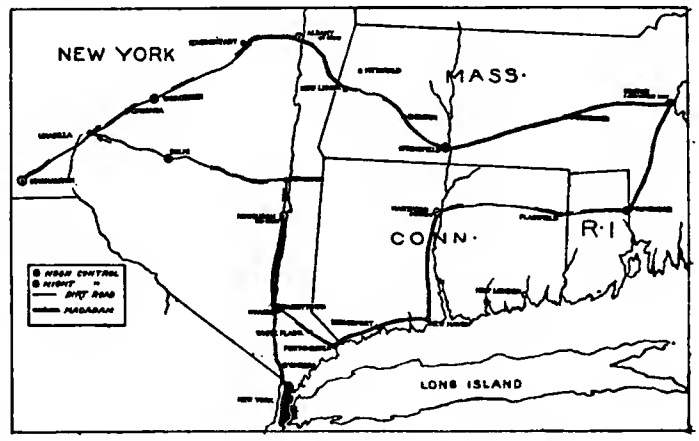
MONTREAL CLUB'S INTEREST IN ROADMAKING.

MONTREAL, Feb. 22.—Twenty-two miles of practically dustless roads will skirt Lake St. Louis this summer, if the Automobile Club's plans, in which the mayors of the lakeside municipalities are interested, can be carried through. In recent years from Lachine to Ste. Anne's a dust cloud hangs over the region every day, during the season of touristing. A meeting has been held, however, between the directors of the Automobile Club of Canada and the mayors of these places, to discuss the advisability of using oil to abate the dust nuisance.

A NEW YORK STATE CLUB'S TOUR.

BINGHAMTON, N. Y., March 1.—In the absence from the East this year of the annual tour of the American Automobile Association for the Glidden trophy, a number of proposed runs have been announced, and of these one that has met with particular favor, since the route and conditions have been made known, is the fourth annual tour of the Binghamton Automobile Club. Six days of touring through some of the most picturesque scenery in this part of the country, with noon controls for luncheon, and rules that will give the competitors a thorough test, and at the same time, a highly pleasant week, is a part of the comprehensive plan outlined.

Night controls at Albany, Boston, Hartford and Newburgh are proposed, with a full day layover in the Hub, and the stops for luncheon will be at Worcester, N. Y.; Springfield, Providence, Tarrytown and Delhi. This route, 761 miles in length, as now figured, but which may be changed in the trip of the pathfinding party, will give those who enter roads of the finest kind in the country. Macadam highways will be covered for nearly the entire distance, the only lapses being a few miles on the first day, a few on the second and a few on the last.



Route of Tour of the Binghamton Automobile Club.

Although the entry blanks have not been sent out and no real endeavor has been made to ascertain the number of cars which may be entered, twenty-eight owners have already signified their intentions of being in the caravan. A valuable trophy is the prize, presented to the club by George F. Johnson, and it will be permanently won by the owner of the car making the best reliability record. There will be two classes, divided at $2,500, class A cars being those sold below that price and class B those sold above it. The rules will call for a definite running schedule, in which the class A cars will be given an additional allowance of from 20 to 30 minutes. In the mornings these machines will be started that much earlier than the larger ones, so that all will reach the noon stop at about the same time, and in the afternoon all will be started together, giving the smaller contestants the additional time in which to reach the finish.

As in other tours through the section of the country to be traversed, one great feature will be the beauty of the scenery and the general interest in the historical points passed. The pathfinding party will make special efforts to collect all interesting data and will include this in the route book, so that the latter will be one for reference at all times. Starting on a Monday morning, June 21, the Susquehanna and Mohawk valleys will be crossed, through Schenectady, into Albany, and at 8

o'clock on Tuesday morning the run across to Boston will be begun, going through the Berkshire Hills, Springfield and Worcester, past the Wayside Inn and many other interesting places. A full day in Boston will be given over to sightseeing.

On Thursday there will be a short run of 45 miles to Providence, a two-hour stop for luncheon and sightseeing, and then a run of 85 miles to Hartford. On Friday the party will lunch at Tarrytown, after a ride through Harriman's estate over his own private automobile road. From Tarrytown to Newburgh will complete that day, and the home stretch will be taken on Saturday, with a noon stop at Delhi. A great deal of interest in this last run will be found in going through the Ashokan Valley, where every village is soon to be destroyed, the timber cleared, every farmhouse, fence, tree, barn and bridge is to be removed, until there is not a thing in sight from hillcrest to hillcrest, and a dam 220 feet high will be built across the valley, forming a great reservoir, 12 miles across at its greatest width, to supply New York City with water.

Although there is still considerable time to elapse before the contest will begin, the full plans will be worked out well ahead. Every member of the Binghamton club, resident or non-resident, will be eligible to enter a car.

MANITOBA'S MOTOR LEAGUE IS PROSPEROUS.

WINNIPEG, MAN., March 1.—The annual general meeting of the Manitoba Motor League, held recently, was largely attended by autoists from all over the province, and the work of organizing for the coming season was carried out with the greatest enthusiasm. The league was first formed in January, 1907, being called into existence by the introduction of a bill into the legislature to control the use of automobiles in the province. From the very commencement the league has met with success, it having secured the passing of the new law in such a way that it has been found to work in a manner entirely satisfactory both to the automobilist and the legislature. The following officers were elected for the ensuing season: Honorary president, Judge Phippen; president, W. Elliott Brandon; first vice-president, D. B. Sprague; second vice-president, Joseph Maw; third vice-president, Major Young; Secretary, W. C. Power; treasurer, P. C. Hagarty, Souris. Consuls were appointed as follows: Portage la Prairie, Harry Stevens; Carberry, Claude Isbister; Neepewa, John Crawford; Gladstone, A. J. Williams; Manitou, Mayor Elliott; Brandon, McClements; Boissevain, W. Elliott; Carman, Dr. Pirt; Plum Coulee, J. Bargen; Cartwright, John Mooney; Carnegie, James Pearson; Virden, H. Goulter. Executive committee at league headquarters, Winnipeg, E. C. Ryan, H. A. Aylwin, Sam Henderson, and L. R. Barrett.

Arrangements were made with the legislature whereby the league will be allowed to affix its direction signs onto the telephone poles, thereby saving expense in the erection of these signs. Arrangements were also made for a good-roads committee to take up with local members of the legistlature the improvements of roads throughout the province.

QUAKER CITY APPOINTMENTS ANNOUNCED.

PHILADELPHIA, March 1.—President L. D. Berger, of the Quaker City Motor Club, made the following announcement of committee appointments at the meeting of the Board of Governors last week: Law and Ordinance—G. Douglass Bartlett, C. Edgar Shreve. Good Roads—R. E. Ross, Frank Hardart, William T. Taylor. Routes and Tours—Edwin H. Lewis, Richard Sellers, A. E. Maltby, A. C. Buzby. House—Frank Hardart, A. T. James, Fred C. Dunlap, N. E. Petty, George G. Meade. Membership—A. T. James, A. T. Stewart. Auditing—Fred C. Dunlap, W. C. Jackson, Dr. W. J. Donnelly. Charles J. Swain was appointed chairman of the Technical Committee and Dr. W. J. Donnelly of the Press Committee, the remainder of these committees to be announced hereafter. Dr. J. R. Overpeck was reappointed as "club pathfinder" and G. Hilton Gautert official starter. A number of plans for spring activities are being discussed.

ACROSS THE CONTINENT IN THIRTEEN DAYS.

LOS ANGELES, CAL., March 1.—The first anniversary of the New York-to-Paris race, coupled with the announcement of the transcontinental race from New York to Seattle, to take place the coming Summer, has aroused intense interest in the coast-to-coast trips, which have been and are about to be made. Speaking of those that have been, how many people know that the continent has been crossed no less than eighteen times? This is a fact, nevertheless, the cars and the number of trips to their credit being as follows: Oldsmobile, four; Franklin, Packard and Reo, two each; Winton, Glide, Buick, Zust, DeDion, Maxwell, Brush and Thomas, one each.

The last-named, it is now announced, is about to have another try at it. The Thomas representative in Los Angeles, Rene A. Brassy, has announced his intention of leaving the southern California metropolis on May 15 at midnight with New York City as his destination and the overthrow of Whitman's long-standing record as his ultimate aim. This record, made in 1906, is 15 days, 2 hours, 10 minutes, and was made over what is known as the short route. Although traveling a longer distance, Brassy is confident of doing the trick in 13 days. The car used will be a six-cylinder, 70-horsepower Thomas with a flyabout body, which will carry four passengers. The route followed will be the old Santa Fé track through the Mojave desert and Death Valley, thence back over the route of the New York-to-Paris race. A relay of drivers will be used, following Whitman's scheme, the car being driven night and day.

Incidentally the Chicago-New York course may have new figures hung up, as it is well known that W. W. Shaw, who will join the party at the Windy City, has been casting longing eyes at the latter for a long time. In setting 13 days as his goal, Brassy has undertaken a very ambitious "stunt," for this is a cut of two days and two hours from the existing marks or 18 per cent. The whole programme calls for an average of over 250 miles a day. While this and better is possible in the East, it hardly seems probable in the Far West, even in May.

HOW A. A. A. WILL SANCTION EVENTS

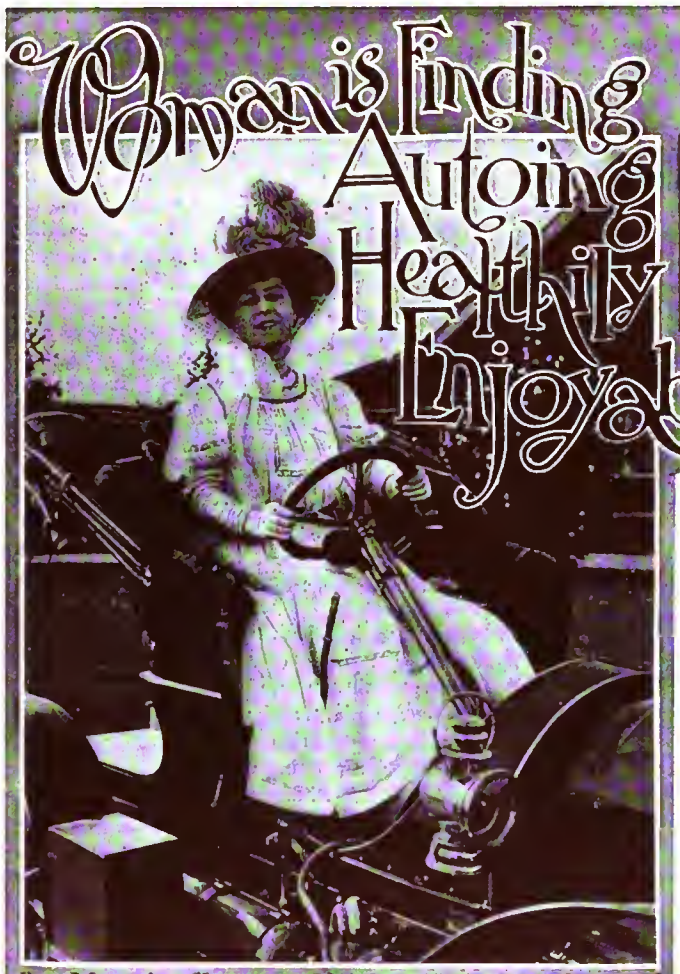
That the control of automobile contests in this country, including track races, other than those which are international, will in the future be vested in the Contest Board of the A. A. A. has been decided through the ratification by the Executive Committee of the terms of the agreement between that body and the Manufacturers' Contest Association, composed of American manufacturers and importers. To insure greater harmony of rules throughout the country and to see that the contests are run upon fair conditions, with responsible parties in charge and standing for the prizes, the Contest Board will hereafter work with an advisory committee from the makers.

The Contest Board is now composed of Frank B. Hower, chairman; A. L. McMurtry and Frank G. Webb, with Alfred Reeves, A. M. C. M. A.; E. P. Chalfant, A. L. A. M., and E. R. Hollander, I. A. S., as the advisory committee. All national events will be under the supervision of these autoists and they will endeavor to conduct the races and tours with less of the petty trouble heretofore noticeable.

A definite schedule of sanction fees has been made as follows: Road race, where a stand is erected, $300; track meeting, $100; track meeting, including 24-hour race, $250; hill climb, $50; endurance contest, $50, and road or beach speed trials, $100. All clubs affiliated with the A. A. A. will be entitled to a reduction of 50 per cent. of these rates.

At a meeting of the Executive Committee of the A. A. A., held February 23, it was reported that there has been good progress in the preparation for the Cobe stock car race to be held near Chicago; that there are several cities which would like to have the second annual good roads and legislative convention next Summer, and that the decision of the Contest Board relative to its jurisdiction over the Quaker City Motor Club endurance run was sustained.

Woman is Finding Autoing Healthily Enjoyable



By Mrs. A. Sherman Hitchcock.

N these days, when it can be truly said that the automobile has "arrived," there are probably few who stop to consider it from a hygienic standpoint. It rejuvenates tired nerves, changes the feeling of dullness to one of energy, gives a keen joy in the beauties of Nature, and the swift pace is certainly stimulating to the circulation. The woman who is afflicted with ennui will find her trouble quickly dispelled by a spin in her car, and, through the medium of fresh air and sunshine, will be physically and mentally the superior of one who dawdles away her time at home over a piece of fancy work or talking the latest gossip.

Air, light and space are said to be essential to health, and, deprived of these, the result would be physical deterioration. There is no way to obtain these three life-giving qualities as satisfactorily as by autoing. The motor-loving woman will never remain at home on account of weather, for wth the many kinds of motor raiment now procurable, the weather has little effect upon the true lover of the sport. Another prime necessity of a woman's life is the alternative distraction or occupation, and there is absolutely nothing that fits so exactly every requirement as the automobile. From the hygienic standpoint it is the amusement par excellence, and, again, it furnishes a very necessary relaxation. There are many women who do not realize the great need for physical as well as mental exercise, and find themselves exhausted and incapable of further effort, when they have accomplished a certain amount. They do not realize that unless one has a healthy body it is impossible to have a healthy brain, and without this one cannot do good work of any kind.

A change of scene is also a necessity, for upon the differencee in surroundings one must depend, to a great extent, for new ideas. These can readily be obtained by going abroad from the beaten track, and for the woman of affairs the automobile is the best medium for this rapid transition from one environment to another. The need of the out-of-doors is an absolute necessity to every one at all times. Of course, one can always walk and walking costs nothing, but, unfortunately, the things that cost nothing are not always those that appeal most to us, and so, for those who can afford it, the motor car is the ideal mode of locomotion. Physicians insist that a certain amount of the open air is absolutely requisite, and if one can combine that air with a moving panorama that is beautiful and interesting, something that lies close to the ideal has been reached. If the owner is forced to make a pleasure of necessity, to a great extent, the auto comes into play with its twentieth century activities, affording the busy woman the maximum of exhilaration in the minimum of time, and by the very force of its rapid progress drives the fresh air into her system. Those women who have never experienced the pleasure that comes from motoring have missed one-half of the joy of living.

If women could only realize the keen pleasure of driving their own car, the pleasure to themselves and the pleasure they can give to others, they would take up driving at once. There are a great many machines built at the present time that can be driven with perfect safety by a woman—for the woman who is rather timid, there is the little electric with its absence of cranking, sparking, changing of gears, clutches or throttle. With only steering and controlling levers and brakes, nothing could be more simple and yet give so much pleasure and comfort, and all the work of shopping, marketing and calling is made a delight. Then, too, there is the added thrill of holding the power in one's own hand, and there is nothing more soothing to a tired and nervous woman than a seat in a smoothly running car. On the other hand, there are women to whom the gasoline car particu-

Mrs. Cuneo at the Wheel of Her Knox Giant.

larly appeals; they are perfectly at home behind the wheel of a big car and are rivalling the masculine drivers. When the weather permits, a brisk spin into the country will blow the cobwebs from the brain and fit one for renewed activity. On a tiresome trip of shopping the car is called into requisition, and this combines a most disagreeable phase of woman's life with one of the enjoyments, for there are probably few women who really enjoy the round of traveling from one shop to another.

Extended Suburban Trips as a Health Producer.

Long trips can be made into the surrounding territory, an impossibility with a horse and carriage, which not only would one be confined to the city limits, but would not give much of the exhilaration that goes with speed. In a couple of hours' time forty or fifty miles of country can be seen, whereas a woman restricted to a victoria, would follow the stereotpyed round of the parks and boulevards. This, after experiencing the delights of touring, seems like deadly dull employment. Autoing is the most perfect cure in the world for an over-wrought condition of the nerves; there are untold possibilities for good in it as a rest cure in this restless age. It gives a healthy appetite and is a pastime which demands sensible living. It gives a delight to life which cannot be found in elaborately decorated drawing rooms. There are many women who can prove that their health has been improved to a really wonderful extent by automobile rides more than any medicine in the world could do; cases, for example, of women who have cured themselves of serious bronchial ailments by spending the greater part of every day in little machines which they can drive themselves. It is not always necessary, but often advantageous, to not only be able to drive cars expertly, but also to take them apart and put them together again, and besides the absorbing interest of new knowledge is always a healthful diversion.

What a Prominent Surgeon Has Advised.

One of the most prominent surgeons in this country recently made the statement that women's arms were fast becoming mere anatomical vestiges, like the appendix, and advised women in general, who could find it possible to do so, to learn to drive their own cars as much as possible in order to exercise their arms freely, the handling of the steering wheel and the manipulation of the different levers giving much needed muscular action. Brachial neuralgia is seen frequently in women, especially in those of the leisure class, who have never used their arms in domestic or material work, and are almost invariably of a nervous organization. A touring trip will produce the same effect as a stay in the mountains; there is an increase in the number of red blood corpuscles and sleep becomes deeper and lasts longer.

The motto of the woman who can motor should be, motor early and motor late, but surely motor, for each and every woman who does can find pleasure, good health, youthfulness and an unequalled exhilaration with the aid of the automobile.

IN the days of our grandmothers, when travel was by diligence or post-chaise, the most suitable headgear was found to be a close-fitting, padded bonnet. To-day, with winter travel in the open air again in vogue—even in the open automobile, far more healthful, by the way, than the closed car—feminine fancy has turned up an old fashion and made it new again.

The advance guard of winter travel has already arrived on the French Riviera, and though blue skies and a radiant sunlight may favor something more airy and open, the bulk of those dainty Parisians who so love a new vogue, and who have journeyed down by road, have in large numbers been coiffed with these dainty and fascinating caps of our grandmothers.

The imaginative Frenchman has also caught time by the wing, or rather the aeroplane, and a progressive manufacturer of clothing for automobilists, aeroplanists, and others has launched two new creations in caps, one called "the Orville" and the other "the Wilbur," each as suitable for automobilists, presumably, as for aeroplanists, and neither differing greatly from the cap or *casquette* of convention, save with a little snugger fit here and a little looser fit there, more or less of a visor, or perhaps a longer or shorter flap.

At any rate, the "styles" have caught on, and now the young sports of Paris who have never got nearer an automobile or aeroplane than the pictures in the illustrated papers, haunt the boulevards, clean-shaven like Wilbur, or with mustachios of Orville, coiffed with the *casquette à la mode.*

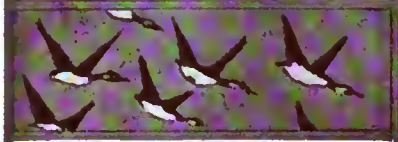
It was ever thus; in the days when we went to Coney Island on an Iron Steamboat we wore a yachting cap like that of the commodore of the New York Yacht Club; and when we thought of learning to ride a bicycle we first bought a cap with a long, peaked visor like a horse jockey's; and now, with automobiles and aeroplanes ever in view, we must have a "Janetzy," or a "Foxhall," an "Orville," or a "Wilbur."

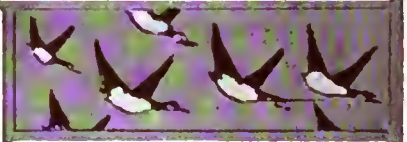
NEW YORK SCHOOL FOR AUTO OWNERS.

Primarily to give owners of automobiles a thorough course of instruction in the care and operation of their machines, a new school, to be called the Stewart Automobile Academy, will be opened about March 20 at 231 West Fifty-fourth street, New York City. A large building has been secured and fitted up, and both men and women will be instructed in automobile and motor boat subjects. There will also be a complete course for chauffeurs given later. The equipment includes 1908 and 1909 engines and other mechanism, with special work outlined in ignition and carburetion. Close attention will be given to road work, and modern cars with double sets of brakes will be employed. The academy will be under the direction of Mr. Stewart, a graduate of Rutgers College, who has been connected with the automobile school conducted by the West Side Y. M. C. A.

BRIMLESS HATS FOR LADY AUTOISTS.

The automobile fashions from the other side include a few novelties that will be of interest. No direct changes are expected but the coats will be worn shorter and cut upon straighter lines than heretofore, while sleeves will be smaller and closer fitting. This will really be an advantage for the close fitting garments will shed the dust better. The new head gear is more radical, consisting as it does of very small, deep crowned brimless hats. Although at first sight seeming very ugly, it is said that one soon gets used to the peculiar appearance. One of the newest innovations resembles Mercury's helmet and, adorned with a plume on each side, will doubtless become popular, being particularly suitable for motoring wear. Other novelties are slight changes in the skirts, which will be plain, and waists liberally adorned with braid and rows of satin buttons.



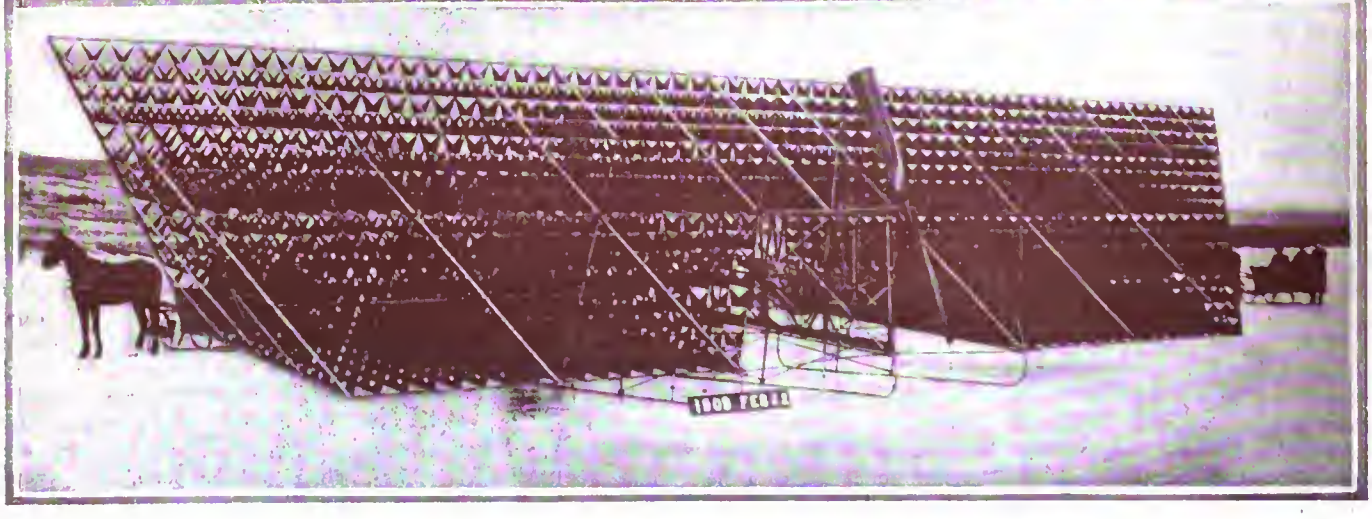


NOVA SCOTIAN AERIAL RESULTS

BADDECK, N. S., March 1.—By flying for four and a half miles over ice-covered Lake Bras d'Or, at a rate of speed of over 40 miles an hour, the aeroplane *Silver Dart*, with which Dr. Alexander Graham Bell and his associates, the members of the Aerial Experiment Association, have been conducting experiments here, has proven to contain the successful features so long sought. Equipped with an eight-cylinder, water-cooled motor of 50 horsepower, this machine last week made its successful flight, and as long as the lake stays frozen the members of the party, who are staying at Dr. Bell's summer residence, will continue their experiments with this machine and the new tetrahedral kite.

These two interesting machines, if such they may be called, are being operated entirely by J. A. D. McCurdy, who designed them, and who, with Dr. Bell, G. H. Curtiss and F. W. Baldwin, form the association. The aeroplane is the fourth motor-driven one built by them this year, and contains many improvements over its predecessors. A great deal of its success is due to its motor, which was built at Hammondsport, N. Y., by Mr. Curtiss, of eight cylinders, placed in sets of four at an angle of 90 degrees, with copper water jackets, a bore of 3¾ inches and a stroke of 4 inches.

Of equal importance is the new tetrahedral kite which Dr. Bell has built, containing 3,690 little cells and weighing 950 pounds with the operator.



TEACHING AEROPLANING NOT A DIFFICULT TASK

By W. F. Bradley

Wilbur Wright's Pupils Bringing the Aeroplane Out of Its Sheltering Place.

PARIS, FRANCE, Feb. 28.—To prove that aeroplaning is not so fraught with dangers and difficulties as is often thought, or that it is a sport or business that should be avoided by those who have great regard for their lives, is an opinion which has been disproven more than ever during the past fortnight, in the flights made under the direction of Wilbur Wright. Just to show that the science can be learned in a comparatively short time, and that it is not so very hard to master the fundamental principles, Mr. Wright has been giving lessons to two or three persons here, and one flight was made by M. Tissandier and Count Lambert, with the former in charge, while the inventor remained upon terra firma.

The propelling mechanism does not figure greatly in the teaching, for almost everyone who is seriously interested understands a gasoline motor and how to control it. In the Wright machine the engine is of standard construction, and is controlled much as is an automobile motor. The first thing to be learned, and upon which much importance is placed, is the method of keeping a balance, just the same problem which had to be mastered in learning to ride a bicycle and it has proved difficult.

Of course, the mere ability to operate the engine and to manipulate the rudders is not more than a beginning, for air currents and many other conditions of the atmosphere have to be studied, but this is a practical start. Mr. Wright has been desirous of proving that aeroplaning is not limited to a certain few, and consequently he has taken up more persons lately than ever before. His sister was one of them, going up to a great height, but she did not do anything in the way of operating the machine. Since then she has made frequent trips.

Count Lambert, however, has become quite proficient in a short time, and M. Tissandier so much so that Mr. Wright has allowed him to make trips unaccompanied, and the one mentioned in which these two were the crew. The fact that there are others who can learn to guide the aeroplane has given a great deal of satisfaction among those interested, for it is a decided step towards making the science or sport more popular. The other day Mr. Wright started with Colonel Vives, of the Spanish aeronautical department, but in starting off the inventor did not seem to lift the rear rudder sufficiently, and it caught in the starting rail and ripped. This necessitated a stop, and the way in which Mr. Wright brought the machine to the ground within 75 or 80 yards of the end of the rail won the applause of the crowd, and of Colonel Vives. The damage consisted of a couple of broken spars and a derangement, which will be

Ready, Count Lambert, Pupil, in Charge.

Wilbur Wright, Comte and Comtesse de Lambert.

Orville Wright Shows How Wind Velocity Is Read.

fixed shortly, delayed by the necessity for completing another machine immediately.

It is expected that Mr. Wright will continue giving lessons so that the commercial aspect of aeroplane building may assume more realistic proportions. Orville Wright, a few days ago, made his first flight since his accident at Fort Meyer, going up in the balloon Icarus, piloted by Marquis de Kergariou.

After an unusually successful flight of about twenty-five miles (400 kilometers), a landing was effected near a small town, Tarbes, from where the party returned to the starting point in an automobile. As final proof of Orville Wright's complete recovery from the unfortunate accident at Fort Meyer last fall, the flight aroused more than ordinary attention.

AEROPLANING IN CHATEAULAND.

PARIS, Feb. 28.—Chateauland has now consoled itself at the loss of the automobile Grand Prix, and has set about gathering together the $20,000 subscriptions which were returned to their donators when the road race was killed. The Municipality of Angers has voted its previous subvention of $5,000, and believes that this example will rapidly draw in from various sources, the total sum of $20,000. With the practical certainty of getting this amount the district has approached the Aero Club of France asking that one at least of its aeroplane races should be held in the district. The subvention, originally intended for the Automobile Club, will be handed over to the Aero Club.

As the Aero Club of France has not less than three races to organize this year, including its own Grand Prix for aeroplanes, the Gordon Bennett aeroplane race, and the French elimination for this event, there is every possibility of the Angers offer being accepted. Not only is the financial assistance satisfactory, but the district and local club will give all necessary aid in organizing, and has a vast tract of land on the banks of the Loire on which a circuit eight miles round can be traced.

The conditions of the Gordon Bennett race are that it should be held on a course between three and six miles round, and that the total distance covered should not be less than 12 miles. The course selected must be announced not later than April 1. It is safe to predict that the first competition for the James Gordon Bennett trophy and $5,000 in cash will be held over the Chateauland course, and also that the Aero Club Grand Prix, under very similar regulations, will be run off on the same course.

It has been asked that the Aero Club of France dirigible balloon race, announced for 1909, should also be held near Angers, but in view of the difficulty in obtaining gas and in housing the airships, it is more than probable that this district will be passed by in favor of the Champagne country.

MACHINE GUNS ON GERMAN BALLOONS.

BERLIN, March 1.—Small cannon and machine guns are to be used in the future by the German military authorities in the equipment of their military balloons. Experiments have been carried out for some time, and it has been decided to use balloons of the rigid Zeppelin type, the danger resulting from the recoil and escape of gas having been overcome by a secret method. For lighter guns a semi-rigid balloon of the Parseval and Gross types will be employed.

AERONAUTICAL AFFAIRS IN GENERAL.

In "My Way of Thinking," by Henry Sturmey, in a recent edition of *The Motor*, the French attitude toward aeronautics is well shown and is interesting in view of the fact that the French government intends to organize an aeroplane show in 1910, and is "resolved to be leaders in aeronautics." Mr. Sturmey writes: "Without disparging the enterprise and initiation which the French have shown in this new field of scientific locomotion, and while they do 'lead' to-day, I cannot help thinking of Count De Dion's boast to me ten years ago, when, speaking of the British as motor manufacturers, he said: 'This is a French industry. It is *ours* and we mean to have it, and you will *never* do anything in it.' When I think of this and of the early history of cycling and automobilism, I can surmise that, although the British as yet have been very apathetic in aeronautical matters, directly they assume commercial importance, British capitalists and engineers will interest themselves in these affairs and will pull back the lead which their French competitors by their more mercurial temperament and earlier efforts have secured. All honor to the French for taking the lead. Whether they will keep it, is for the future to decide. I have my doubts. But what an example is this decision of the French Government to our own! Where would you find in this country the Government, either of the country or of a municipality, spending public money and interesting itself in the pushing of any particular form of industry?"

AMERICANS TO FLY ACROSS CHANNEL.

NEW YORK CITY, March 1.—Feeling that the success attained warrants their seeking broader fields of activity, the members of the Aerial Experiment Association have arranged to send an American aeroplane to England in May, to try for one of the two prizes offered for the first successful aeroplane flight across the English Channel. It will be modeled on the plan of the successful *Silver Dart* and work upon it will commence at once at Hammondsport, N. Y. It will probably be in charge of J. A. D. McCurdy and F. W. Baldwin, two members, who have been at Baddeck, N. S., with Dr. Alexander Graham Bell conducting experiments upon the ice with the *Silver Dart* and Dr. Bell's new tetrahedral kite. The association is now prepared to build aeroplanes for practical uses and upon orders.

PREPARATIONS FOR THE NATIONAL RACE.

On June 5 the national balloon race under the auspices of the Aero Club of Indiana will start from the track of the new automobile speedway, at Indianapolis. Aeronauts in all parts of the country are taking great interest in the proposed balloon race, among them being Cortland F. Bishop, president of the Aero Club of America, with which the Indiana club is affiliated, and also A. Holland Forbes, vice-president and chairman of the contest committee of the Aero Club of America. A gold medal will be given to the winner of the race and he will also be awarded the national championship. G. H. Curtiss, who won the *Scientific American* trophy for aeroplanes last July, will make an exhibition with his aeroplane *Gold Bug*.

A 50-horsepower, six-cylinder aeroplane engine is now being built at the Kilburn works of the Simms Manufacturing Company in England, fitted with a special carbureter and a Simms magneto. It is being made by F. W. Simms for a new aeroplane being constructed by S. F. Cody and will weigh only 4 1-2 pounds per horsepower, the bore and stroke being 110 mm., and the cylinders set at an agle of 120 degrees.

There is some little surprise in German aeronautic circles at the fact that a Baldwin balloon has arrived in Berlin for the well-known aeronaut Captain Hildebrandt, as the press plainly confesses it cannot conceive why the airship was brought from the United States, which, it asserts, is not so far advanced in this branch of sport as Germany. But Captain Hildebrandt probably knows why!

Of and By Those Prominent in the Industry

C. W. Churchill, sales manager of the Winton Motor Carriage Company, in speaking of the great demand for automobile parts and the fact that a large number of the makers are unable to fill orders, said a few days ago: "We don't smile at anybody's misfortune, but we are mighty glad that we make practically all Winton Six parts in our own plant. That enables us to deliver cars according to promise. Winton Six buyers will be using their cars this Spring and Summer when some other buyers will still be wondering why they can't get delivery." At the Cleveland show one maker of small parts confessed that if the orders now on his books should stand without a single addition his plant would have to run night and day from now until September 20. Of course, that means that more than one automobile manufacturer will be unable to secure parts that he expects to use in his 1909 cars.

A Noted Foreigner Is with Us.—American automobile factories, during the past couple of weeks, have been visited by one of the most noted foreigners connected with the automobile trade, Frederick R. Simms, of Simms-Bosch magneto fame, who is making a thorough round of the industry in this country. Mr. Simms has not only attained American fame through the use of his magneto, but also through the knowledge here of his prominence in English and continental automobile affairs. He is the founder of the Royal Automobile Club and also of the Society of Motor Manufacturers, and was the first vice-chairman of the former and president of the latter for two years. Professionally, he is best known in connection with ignition subjects, although he is really as much interested in automobile manufacture itself. He has figured prominently as a consulting engineer and designer, and has introduced the use of the gas engine into many spheres aside from that of automobiles. At present he is working upon its development for use in aeronautics. It was he who introduced the Daimler engine into England, after first seeing the German production in 1888 at Bremen, and he became a director of the famous German concern, successfully forming a syndicate to work the Daimler patents in England. From Mr. Simm's account of the early days of the industry and of how he became engaged in it is most interesting because of his close touch with its growth, from the time when he was referred by Daimler factory officials in discussing ignition subjects with them, to a German machinist of ideas. The Simms-Bosch magneto was the result of the new acquaintanceship, bringing the original Bosch down from a size 16 inches in height to one suitable for use on automobiles.

F. R. Simms.
From "Automotor Journal," London.

As to future changes in construction, Mr. Simms predicts some important ones, although they may not be thought of now, except as ideas, drawing his lessons from improvements made in the past, such as those to the steam engine, which, when perfected in its reciprocating types, was followed by the turbine. Automobile designers are now working upon hydrocarbon turbines with more or less success, the principal difficulty being in caring for the excess of heat. The Knight motor, he mentions as an improved type. In interviews upon the subject of gasoline motor design, he favors cylinders cast in pairs, with valves in the head and a hemispherical compression chamber, a single camshaft, thermo-syphon cooling, selective sliding gear transmissions, and shaft drive. The number of cylinders depends upon the power necessary, four cylinders up to a certain size and then six. This is true, also, of his idea upon the number of speeds used in the transmission, medium priced and powered cars having three and the larger ones four.

An interesting point by Mr. Simms is that, to a great extent, the French designers as a whole are behind those of two or three other countries, because a number of the ideas which are now becoming popular were originated in these other countries.

What Gruenfeldt Noted in Europe.—Emil Gruenfeldt, M. E., E. E., who is the designer and chief electrical engineer of the Baker Motor Vehicle Company, of Cleveland, has recently returned from Paris and Berlin. Mr. Gruenfeldt reports that the various types of electric motor cars now in use in the principal cities of Europe he cannot perceive any substantial benefit to be derived there in the line of batteries and motor construction. He says that European cars are not built to render the substantial service demanded of electric motor cars in this country, and that while the batteries in use abroad are of very high capacity, having thin plates, their life of active service is reduced; and the chief merit of European electrics appears to be their comparatively high speed.

Emil Gruenfeldt.

Mr. Gruenfeldt maintains that the main parts of the electric motor car, such as motor, controller and wiring, in connection with the necessary smaller attachments, are, as a whole, worked out very poorly in the European car and not capable of yielding the long life and high efficiency of the high-grade American car. The European production appears to be confined principally to broughams and cabs, and there appears to be a large field for the marketing of a properly designed small electric motor car of the high-grade American type.

Stewart McDonald, vice-president and general manager of the Moon Motor Car Company, of St. Louis, in commenting upon the great activity of his concern said recently: "The volume of our business has increased to such an extent that the 1909 output, which we planned in making our advance orders for material, has already been sold or contracted for. We have found that we must turn out more cars than we planned this year. To do this we increased our working force 10 per cent. just after the St. Louis show, and as soon as our facilities will permit it, we will probably make a further addition to our factory force. Fortunately, the Moon factory was built with this growth of the business in view, and we have plenty of room at our plant."

James Joyce, manager of the Alco car manufacturers, who may fairly be taken as a spokesman for the makers of the cars of highest grades and prices, with regard to the increase of cheap and medium-priced cars on the market this year, says: "Let them come; the more the merrier; they have their field; they make new converts and send a lot of them higher up for their second cars. These low-priced cars bring many new faces into the automobile field. Some cannot afford to pay more, but will be able to do so later. Some others can afford to pay the top price, but figure that they can buy two or three cheap cars for

the price of one of the others. They are the sort who must learn in the school of experience. Seasoned automobilists like a car that stands seasoning; that they know and understand as a friend. They figure on the economy in the long run, counting the cost per thousand miles, the percentage of time the car is out of commission, the delay, annoyance and deprivation endured, or the comfort, convenience and confidence enjoyed. All these things count in a car, the same as they do in house furnishings or clothing."

George M. Stadleman, secretary and general sales manager of the Goodyear Rubber & Tire Company, in speaking of the great amount of tire trade centering around Akron, the value of the business to be done there during the coming season, and, from this, drawing a deduction as to the number of automobiles to be manufactured in 1909, says: "It is practically conceded that about 75,000 automobiles of different sizes will be manufactured in 1909, and to furnish tires for these and to renew tires on the ones already in existence means a production of $15,000,000 worth of tires alone from the city of Akron. The tire industry was never better in every part of the country, and so great has been the increase in that handled by our Boston branch that enlarged space has been found necessary.

"This has led to the purchase of a lot and the erection of a five-story building, and it has just been occupied. At Akron we have just completed a new vulcanizing room of concrete and turrent construction over the Cuyahoga River. Eight presses, each of which will vulcanize 14 tires at once, have been installed and in combination will give facilities for an enormous product. Still another building of brick, concrete and steel, five stores high, is now being built."

H. H. Rice, manager of the Waverly Company, has advanced a new comparison to explain the care and management required for a storage battery by likening it to a horse. He says: "The same thought and attention that every intelligent man bestows on a horse should be applied to a battery, and the same degree of intelligence that is required for the care of a valuable horse is sufficient for proper management of a battery. Charging a battery is much like feeding a horse. It should be done regularly, at the proper times and within proper limits. If you were driving a horse on short trips about town, you wouldn't feed him at every hitching post. Neither should you put your battery on charge every time you house it in the garage. You should wait until the battery has been discharged down to a certain point and then give it a full charge.

"But a full charge doesn't mean overcharging any more than a good feed means overfeeding. Overfeeding a horse may produce fever, and just so overcharging a battery will raise the temperature of the plates unduly and injure them. On the other hand, you wouldn't work a horse until he had used up the last atom of strength in his body, and so you shouldn't use a battery until every volt of current has been discharged. The rule is not to discharge a battery below 1.70 volts per cell—or for a 30-cell battery, 51 volts. Again, if your horse has been worked pretty near the limit of his strength, you won't allow him to stand long in the barn without a feed. Just so with a battery. It should be kept charged whether you are going to use it or not. Moreover, it should always have a sufficient supply of water. This is just as true of a horse.

"Of course, the analogy might be pushed too far, but it is a general truth that if a man will give the same intelligent consideration to the needs of his storage battery as to those of a 'hay motor,' the care of an electric will prove far easier than that of a horse, and the satisfaction of its use far greater."

F. M. Hoblitt, general sales manager of the American Locomotive Company, stopped in Minneapolis for a day on his return from an extended trip on the coast, and he is all enthusiasm about the conditions from Minneapolis to the Pacific. While in San Francisco he closed a deal with three of the largest hotels for 25 American Locomotive taxicabs for spring delivery, and says that this feature of the industry is just coming into its own on the coast. He also opened an exclusive American Locomotive agency in Los Angeles, and while there personally sold three cars within a few days of each other. The Victoria Motor Car Co., of Minneapolis, the Alco agents, Mr. Hoblitt says, is slated to do a large business. Mr. Hoblitt recalled the days when the inhabitants of Minneapolis chased him up Nicollet avenue, not for any crime, however, but to see his automobile go. Since that time he has been here many times and takes a great interest in the growth of the automobile industry in Minneapolis and the Northwest.

NOTED MOTOR BOATS FOR PALM BEACH.

By John C. Wetmore.

Palm Beach, Fla., March 1.—Preparations for the fifth annual motor boat carnival and races of the Palm Beach Power Boat Association, which will take place on Lake Worth, March 16 to 19, are now complete. Indications point to the most successful regatta and notable power boat carnivals in this country. Leland Sterry, secretary of the association, is in communication with owners of some of the fastest and best known speed crafts in the country, and every inducement in the way of favorable freight, railroad and hotel rates is being offered.

No finer sheet of water for motor boat racing is available in this country than Lake Worth. A course measuring 2 1-2 nautical miles straightaway has been surveyed, showing a miniumum depth of 12 feet and a maximum of 20 feet. There is practically no tide on the lake, thus permitting top speed in each direction. Between $2,500 and $3,000 represents the total cash value of the magnificent trophies the association has put up for competition. Foremost among them is a $500 silver trophy, 25 inches in height, offered for the best mile record made during the meet. Then come the $400 trophy offered by the Beach Club for the endurance contest on the final day, and the $300 cup to be competed for by Florida built boats.

The first day of the carnival will be devoted largely to speed trials. Timers will be placed at every stake to secure the records of the boats. Theodore D. Wells will use the figures thus obtained as a basis for the handicaps during the remainder of the regatta, a system which has proved most satisfactory during the four years of his administration as handicapper at these regattas.

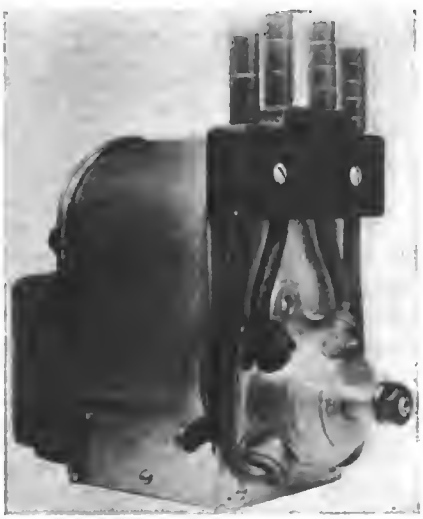
The entries will close the day before the start of the regatta, though they may be made at once with Leland Sterry, secretary, the Breakers, Palm Beach, Fla., or with W. J. Morgan, Thoroughfare Building, Fifty-seventh Street and Broadway, New York City. Among the entries already received are: *The Buffalo Courier*, W. J. Connors, Buffalo; *Trente Sept* and *Crusher*, George Gingras, Rockledge; *Kitty Sparks*, Charles Furthmann, New York; *Messenger Boy*, George E. Andrews, Palm Beach; *Possum* and *Flying Fish*, Lieut. Hugh L. Willoughby, Newport; *Dewey*, W. T. Coachman, Jacksonville; *Dennison III*, Com. Christopher Gallagher, Philadelphia; *Dixolite IV*, Jupiter, Fla.

MUNICIPAL CAR GOES 100,000 MILES

Chicago, March 1.—Some one interested in figures has dug up the fact that the city of Chicago has no less than 14 automobiles in service, divided as follows: Police Department, 2; Fire Department, 2; Board of Improvements, 2; Health Department, 2; City Physician, 1; Commissioner of Public Works, 1; Bureau of Streets, 1; Bureau of Engineering, 1; Park Commission, 1; Department of Track Elevation, 1, and Council Committee, 1. Any one who thinks that municipal cars do not see service will be greatly surprised to know that the record is held by Superintendent Doherty's Street Department machine, which has traveled 97,000 miles in two years. That this is not an isolated instance is shown by the additional statement that Deputy Commissioner Paul Redieske, of the Public Works Department, traveled 52,000 miles in a single year—1908. Another machine, recently purchased, has gone 5,000 miles in two months of the winter, which is at the rate of 40,000 miles a year. Considering the usual treatment of municipal equipment this example of useful work by a city machine will be of interest to taxpayers, who foot the bills.

PITTSFIELD INDUCTOR TYPE H. T. MAGNETO.

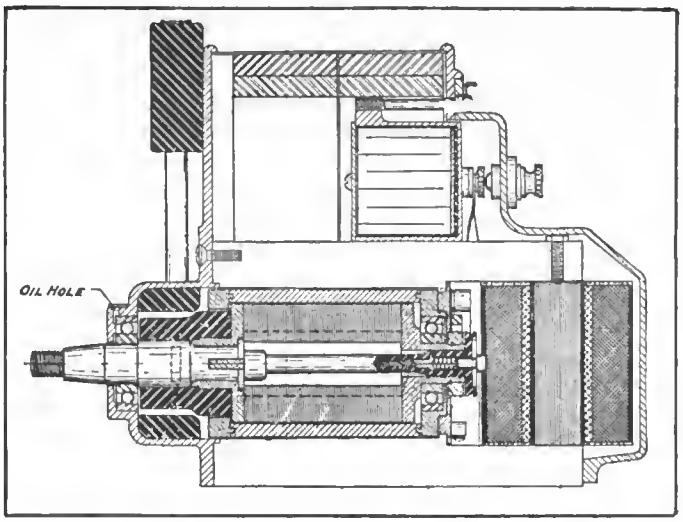
DALTON, MASS., Feb. 29.—Developments in magneto design have followed one another so rapidly during the past few years that it has been difficult to keep track of them, and their variations are coming to be such that it is equally difficult to classify them. This is the case with the new Pittsfield high-tension magneto that made its début at recent shows. It consists of a generator of the inductor-alternator type, but embodies numerous features that distinguish it from previous attempts in this direction, beside auguring well for its success in service. Imported steel of a special grade is employed in the shape of the usual permanent magnetic field of conventional compound horseshoe design, but the magnetic circuit marks a radical departure from practice in this field hitherto. Being of the inductor type, the magneto generates the current at low tension, but the induction coil is not only incorporated in the machine, but its core is made to serve as part of the magnetic circuit. The pole pieces are of laminated construction, and attached to them top and bottom are two bars, measuring about ¼-inch thick by ¾-inch wide, and extending about 1½ inches beyond the permanent field at the circuit-breaker end of the machine. Between the outside terminals of these two extensions of the magnetic circuit, the induction coil is clipped, its built-up core making a close fit between the two, though it is so mounted as to be readily removable for inspection or replacement. Next to the bore of the polar gap is placed a four-part sleeve, in which revolves the inductor.



General View Pittsfield Magneto.

The four members comprising this sleeve are fastened at the distributor end of the magneto to a circular bronze plate and serve to provide for changing the time of occurrence of the impulses, this method giving a range of advance of 30 degrees at the magneto, or the equivalent of 60 degrees on the motor. As it is of the inductor type, there are no moving windings, the impulses being generated directly in the primary of the coil already mentioned. Just behind this is placed the circuit breaker. Due to the use of the sleeve already described, the magneto generates four impulses per revolution, but in order to comply with the usual requirements on four-cylinder motors only two are utilized.

Quite a departure is to be found in the condenser, which is circular in form and is assembled on a special machine devised for the purpose at the Pittsfield Spark Coil Company's factory in this city. Owing to the usually liberal condenser capacity provided, no sparking is visible at the platinum contacts at any speed, while the current generated is such that a very long spark is produced at a low r. p. m. rate, due in large part to the fact that the inductor is laminated. The efficiency of the generator is further enhanced by the extremely small clearance between the inductor and the sleeve obtained by special methods of manufacture devised at the Pittsfield plant. The field poles as well as the inductor are of laminated construction, and after they have been assembled in place, the magnets and poles are jigged and the tunnel is then rough bored. The jig employed is extra heavy and holds this foundation of the generator securely against movement in any direction. After the completion of the first cut, lapping is resorted to, and is subsequently followed by a very fine finishing cut, taking off about .002-inch. The faces of the laminated inductor are ground to an extremely close finish, and it is mounted on F. & S. annular ball bearings.

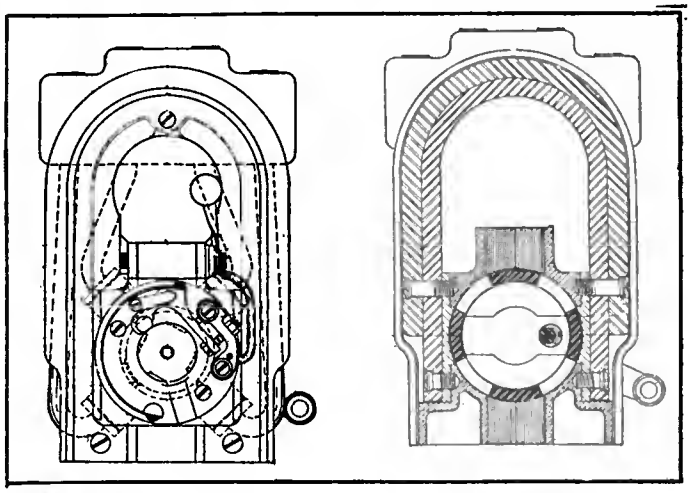


Longitudinal Section Through the Pittsfield Magneto.

An unusually high degree of efficiency has been attained in the construction of the induction coil, this measuring scarcely three inches in height over all by about 1½ inches in diameter. The core is of the usual laid-up construction, annealed iron wire of special grade being employed, upon which the primary is directly wound, oil silk being employed for insulation, while the winding itself consists of enamel insulated wire having a much higher factor of resistance than the usual silk covering and occupying considerably less space. The secondary winding is held between fiber washers and is put on in the usual manner, the entire coil being subjected to a bath in a special insulating compound applied in an impregnating tank at high pressure.

In testing out the first magneto of this type, it was run at 2,300 r. p. m. for the equivalent of more than 40,000 miles travel of a car, while the first series of machines to come through was subjected to a 10-day test at the same speed running constantly for 10 hours a day, without revealing any signs of weakness. As applied to a Franklin air-cooled motor in Mr. Muller's laboratory at the Pittsfield factory, the magneto exhibited unusually good starting qualities, the motor getting under way from cold on the first compression for a score of times in succession, there being no necessity of making a complete revolution of the crank in order to insure a start.

The plant of the Pittsfield Spark Coil Company, at Dalton, Mass., is probably one of the largest in the country devoted exclusively to the manufacture of ignition specialties, everything, with the exception of wire, being turned out in the home factory.



End View Circuit Breaker. Cross Section of Same.

AERIAL PROGRESS INDEBTED TO AUTOMOBILE.

How few people there are who have the correct viewpoint of the very recent and almost startling progress made in navigating the air! To place the credit where it belongs is a hard matter, and one that would lead to a war of words and hard feeling, but to ascribe all of that progress to the men prominent in aeroplane work is certainly a mistake. The vast advancement made in automobile engine construction surely paved the way for what followed, and therefore the automobile industry as a whole must shine by reflected light, so to speak. Aeronautical men generally are free to admit that the lightweight motor has made the two-hour flights not a possibility, but a probability, and, more, a reality. This statement, when analyzed, allows but one rational deduction, viz., that without the ultra-light engine we would be today where we were several years ago. To descend to slang, then, the engine is the "whole thing." Further, the engine is distinctly an automobile production, therefore the inference is that the airship is an automobile production, not *per se,* but indirectly.

Now, to bask in this reflected glory a little bit, let us see what the industry has done for the internal combustion motor in the way of reduction of weight and improvement in reliability. Ten years ago the automobile that would run at all was very uncommon; in fact, it was a curiosity. The smooth-running, quiet motor of to-day was but a dream, the stern reality was the necessity of keeping the engine in motion for more than a minute or two. As to weight, the motor weight of those days ran up to two or three hundred pounds per effective horsepower. This was pulled down by successive stages to one hundred, eighty, sixty, forty, and so on. To-day there are many motors which weigh close to ten pounds per horsepower. For aeronautical work this figure is cut in half, but in so doing the effective life of the motor is reduced an equal amount. At any rate, there is a great deal in the contention that the automobile is the father of the airship and therefore entitled to its share of credit.

To eliminate this ever-present factor of uncertainty and still retain the light construction is the engine builder's problem to-day. In this work, too, the automobile firms should find an outlet for a vast amount of surplus energy and one that is well worthy of extended attention, not only from the measure of glory to be received but also from the more practical viewpoint of profit. This is readily seen by considering a simple question, thus, where will aeroplane builders of to-morrow obtain engines of light weight, in large quantities?

* * *

PRACTICALLY CONSIDERING THE LABORATORY.

In former times the laboratory was a mysterious place in which it was not the custom to venture, unless with hat off, muffled tread and voiceless. The director of the premises was supposed to be one of the few mortals who could cope with the problems, and as to the equipment used, it was of the most baffling description. It is no wonder that the testing of materials was left to the makers thereof, for the most part, excepting in rare cases, taking into account such users of vast quantities of materials as the Government.

When automobiles came into vogue and it looked as if materials were found to be wanting, in some respects at any rate, the question of the ability of the materials had to be arrived at and tests for the purpose had to be made. The designers of automobiles soon found that reliance could not be placed on the tests that emanated from sources under the wing of the makers, and an attempt was soon made to get at the bottom facts, and by so doing look the problem squarely in the face.

It was then ascertained that all the so-called impact tests fell short of the truth by a distance equal to a stellar unit of measurement, and that the "dynamic ability," in relation to which publicity agents raved, was frequently but a myth. In the meantime men of ability, actuated by pure motives, took hold of the problems, and while the situation savored of much complexity, the fact remains that the problem bowed to honest endeavor in much the same way that the mightiest oak pays humble tribute to the breath of the storm king.

Of the notable advances in recent times it is fair to say that the Shore Scleroscope, used in testing for hardness, is well worth more than passing notice in view of its good accuracy, great flexibility and the fact that it is simple enough to put into the hands of the artisan upon whom reliance must be placed for uniform results in the long run. The principle involved is of interest in that it takes into account the phenomena involving impact, and measurements do not have to be made, the nature of which are beyond the skill of workmen.

N. A. A. M. FAVORS DETROIT START FOR A. A. A. TOUR

NEW YORK CITY, March 3.—Attended by a number of important figures in the automobile trade, the regular monthly meeting of the members of the executive committee of the National Association of Automobile Manufacturers was held this afternoon and several affairs of importance to automobilists considered. The Chicago show was reported a success; it was decided to aid Detroit in its campaign to secure the start of the Glidden Tour; it was also agreed that its counsel should fight the anti-auto legislation at Mount Desert, Me., and committees for the following year were announced.

In his report upon the exhibition at Chicago, General Manager Miles showed that the great affair had been a success, not only from the amount of the net receipts, but also from the amount of business transacted by those exhibiting machines, and the makers were greatly pleased at the result. Inasmuch as Detroit has become the greatest automobile manufacturing city in the world, it was the opinion that it really deserves to have the start of the annual endurance contest, and resolutions were adopted asking that such should be decided by the A. A. A. Contest Board. Fully a dozen entries from that city alone will probably be made if the tour starts there, and there will be unbounded enthusiasm. The pathfinding car will leave Detroit within a couple of months.

For some time there has been a growing agitation at Mount Desert, Me., against the use of automobiles on the island, and it has been found, upon investigation, that a great deal of it is prejudice, according to the N. A. A. M. opinion. Therefore, at the meeting this afternoon, the executive committee authorized its counsel to do all possible to prevent the passage of legislation preventing the use of automobiles there.

S. D. Waldon, of the Packard Motor Car Company, was in the chair for the first time since his election as president. The others present were: S. T. Davis, Jr., Locomobile; W. R. Innis, Studebaker; R. D. Chapin, Chalmers-Detroit; W. E. Metzger, E-M-F; W. T. White, White; L. H. Kittridge, Peerless; A. L. Pope, Pope; Thomas Henderson, Winton; Charles Clifton, Pierce Arrow, and S. A. Miles, general manager.

The following committees were nominated by the president and approved to stand during the coming year:

Membership—S. T. Davis, Jr., Benj. Briscoe, C. C. Hildebrand.
Legislation—W. R. Innis, R. D. Chapin, C. G. Stoddard.
Roads—R. D. Chapin, S. T. Davis, Jr., L. H. Kittridge.
Show—W. E. Metzger, A. L. Pope, Thos Henderson.
Contest—H. O. Smith, W. T. White, W. E. Metzger.
Audit—Benj. Briscoe, S. T. Davis, Jr., Chas. Clifton.
Traffic—A. L. Pope, W. R. Innis, C. C. Hildebrand.

CROSS-THE-COUNTRY TO SEATTLE FAIR.

'Tis possible that the cross-country endurance run from New York City to the Seattle Fair may start about the middle of May in order that there shall be no possible chance of interference with the annual Glidden tour of the American Automobile Association. This suggestion is made by the contest committee of the Automobile Club of America to the promoters who have obtained a conditional international sanction from that committee.

Originally the date of the start was to be on or about June 1, but it seems that an objection was made to this date from several sources, which is probably the cause of the club's committee suggesting another date.

The International Association of Recognized Automobile Clubs has no rules governing a transcontinental endurance contest, nor did it take any heed whatever of the 1908 event of a similar sort which encircled the globe. Hence, it is predicted by some who are in a position to know the trend of events that the old misunderstanding with the A. A. A. and the A. C. A. may have another lease of life. Others claim that there is no chance whatever of friction and that whatever difficulties may arise will receive amicable consideration—in fact, assurances of this sort are said to have been mutually interchanged.

One significant thing is pointed to in the presence on the advisory board of the Manufacturers' Contest Association of a member of the contest committee of the A. C. A.

In the meantime T. F. Moore, of Mills & Moore, has returned from his Seattle visit surcharged with enthusiasm and confidence. A tentative route has been chosen, and other arrangements are gradually being decided upon.

One rule as first proposed has been changed, so that in addition to the frame, the cylinders, transmissions, front and rear axles and crankcases will be stamped before the start, and each car will be allowed two complete extra sets, one to be kept for use at Chicago and the other at Cheyenne, Wyo. They will be held at these points by responsible parties.

At Seattle the Exposition authorities will erect a building to house the machines, at the conclusion of the trip, for exhibition purposes, and railroads will file rates with the Interstate Commerce Commission allowing them to ship the cars back East at half the usual rate, and guarantee to deliver them at Chicago in ten days. The rules and entry blanks have been issued and the contest committee of the Seattle Automobile Club nominated to take charge of the race from the western end.

SOME OHIO WINTER COMPETITION.

CLEVELAND, March 1.—A rough and ready go-as-you-please road race to Akron and return between a Cadillac and Jackson for $100 a side, won by the Cadillac, and a sprint to Toledo and back through the mud by a sealed Maxwell marked the closing days of the Cleveland show this year.

There has been considerable talk between the Cadillac and Jackson people here of late, culminating in a challenge to the Jackson to race between Cleveland and Akron and return for a side bet. The contest, held under the auspices of the automobile department of the Cleveland *Plain Dealer*, started from the show building at 7 A.M. Saturday morning. The eighty miles was covered by the Cadillac in 5 hours 25 minutes, while the Jackson went into a ditch and bent the gear-shifting lever so badly that low speed could not be used.

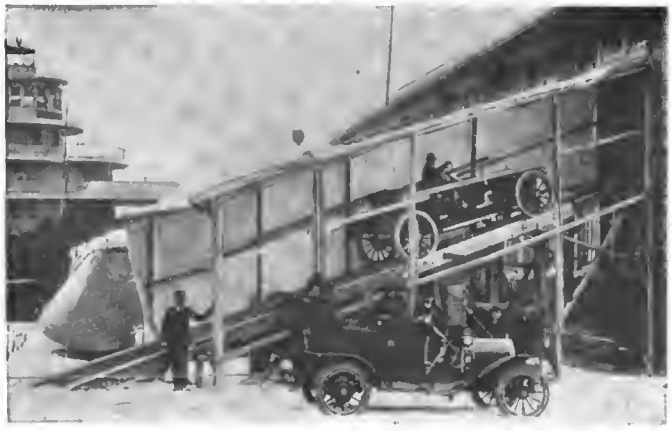
The Jackson people have come back at the Cadillac representatives with a return challenge, allowing the Cadillac people to make their own terms. What the final outcome will be is not yet known.

The Maxwell run was to test out a green car with everything sealed up. A four-cylinder roadster was taken off the show floor and pressed into service. The hood, coil box and tool box were sealed by the automobile editor of the *Plain Dealer* and the car started. The mud was terrible, the axles often dragging for miles. The machine left here Friday morning at 6 o'clock, and got back Sunday at 6:30 P.M., after a trip which most people said was impossible. Not a seal was touched during the entire run, and the car is now being used to demonstrate around the city streets.

FORD CLAIMS PATENT INFRINGEMENT.

DETROIT, March 1.—Claiming that several automobile manufacturers in their rear-axle constructions are infringing upon a basic patent covering this, Henry Ford, president of the Ford Company of this city, has threatened to bring suit against these concerns, the names of which are not, as yet, made public. The patent, No. 747,909, was taken out in 1903, and, it is claimed, covers a great many of the rear constructions now used in prominent cars.

Probably the first aeronautic professorship in the world has been instituted at Gottingen University, where Professor Prandl has been nominated to lecture on aeronautics in general and their practicability for universal use.



How E-M-F Pulled Cars into Detroit Casino.

ONE WAY TO CLIMB A 30 PER CENT GRADE.

DETROIT, MICH., March 1.—A difficulty which confronted the management of the Detroit show the other week was how to get a number of the heavy cars up to the second floor, especially when the runway allowed by the city give a rise of 13 feet in 40, slightly over 30 per cent grade. It was finally accomplished by having LeRoy Pelletier's E-M-F touring car attached to one end of a block and tackle, after a truck had failed to appear and the use of horses scorned. At first the car was unable to secure traction, its wheels spinning, even though chains were on the tires. By loading a number of heavy men into the tonneau, this was overcome and some very heavy cars pulled up the steep incline, one limousine weighing 5,500 pounds.

DETROIT TO HAVE ANOTHER, YET UNNAMED.

DETROIT, March 1.—The Hudson Motor Car Company is the latest addition to Detroit's automobile colony. The incorporators of the concern are J. L. Hudson, one of Detroit's largest merchants, who is identified with a great number of local industries; R. B. Jackson, George W. Dunham and R. B. Jackson, trustee. It is a closed corporation, with $100,000 capital, all of which has been paid in. Mr. Hudson will act as president.

Mr. Jackson was formerly general manager of the E. R. Thomas Motor Car Company, and has been identified with the industry in an executive capacity for some years. George W. Dunham was until recently chief engineer with the Olds Motor Works, at Lansing, and is recognized as a designer of ability.

Details of the car have not yet been announced. For the present the company will occupy the plant formerly used by the Northern Motor Car Company.

Fur-coated Testers of Pierce Great Arrow Cars.

Immune to all kinds of weather, this squad of men is employed by the Pierce Arrow Motor Car Company at Buffalo to give all of its cars a dash over the roads before shipping them. Two of the men in the picture have been with the company since it was started in 1901. During the recent storm, though the ground was covered with a foot of snow, their work was not interrupted.

Champion Frank Kramer in His Jackson Car.

THE WORLD'S CHAMPION DEMONSTRATOR.

NEWARK, N. J., March 1.—It is seldom that a real world's champion volunteers as an automobile demonstrator, but Frank Kramer, the cyclist, who for three years was the amateur and for seven years the professional champion rider of America, besides winning one year Europe's most important race, volunteered as such at the Newark, N. J., show last week, using his own 40-horsepower Jackson car, to aid the Essex Automobile Company, from whom he purchased the machine. Kramer successfully filled the part of demonstrator, selling several cars.

LOCOMOBILE HAS APPRENTICE SCHOOL.

BRIDGEPORT, CONN., March 1.—The graduation of employees as apprentice machinists is a happening which does not often occur in automobile factories, but which did last week at the plant of the Locomobile Company of America in this city. Feeling that additional knowledge and interest on the part of its mechanics would benefit the company directly, a combination course for apprentices has been arranged so that boys who work in the big factory on the water front are able to go to school a part of four days every week.

The school is the industrial department of the local Y. M. C. A., toward the maintenance of which each factory sending apprentices contributes. The Locomobile Company has established a three-year course, allowing the boys to go to the school two hours each day and work in the factory during the rest of the time. It has been so arranged that all are not away from the plant at the same time, and their absence is thus not greatly missed. They are taught simple arithmetic, algebra, mechanical

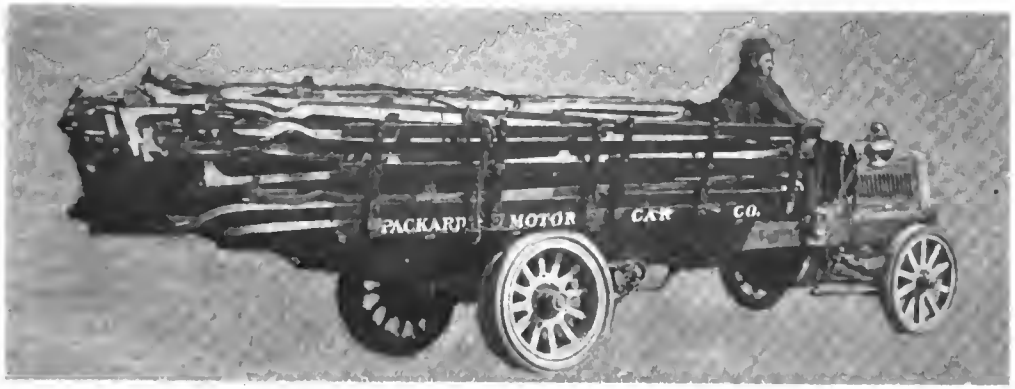
drawing, geometry, grammer and similar subjects. When the course is completed the "graduate-apprentice at the machinist's art and trade" is given a neat lithographed diploma.

STEADY PROGRESS OF THE COMMERCIAL VEHICL.

THE situation to-day in the field of the self-driven or power vehicle is such that the men most interested in that line count that day lost which does not chronicle some new or different commercial vehicle installation opening up an entirely new field of usefulness. The largest development of the past few months has been in the line of municipal use as police, fire, hospital, emergency, and similar service. Not that other branches have stood still, but this field has shown a wonderful increase.



Packard Truck That Has an Admirable Record for Efficient Service.

In the transportation of passengers, in our large cities, the increase has been less spectacular and more on the order of slow but sure. Thus in suburban traffic and in the transporting of people between towns that have poor railroad facilities or none at all, the past year has shown an expansion that was particularly gratifying. In this connection, one of the accompanying illustrations shows an omnibus installation in Washington which marks the public demise of a much-despised horse service. In marked contrast with the evil smelling and poorly lighted old herdics, will be the new clean omnibus, lighted by electricity.

Truck Undergoes Two Years of Severe Service.

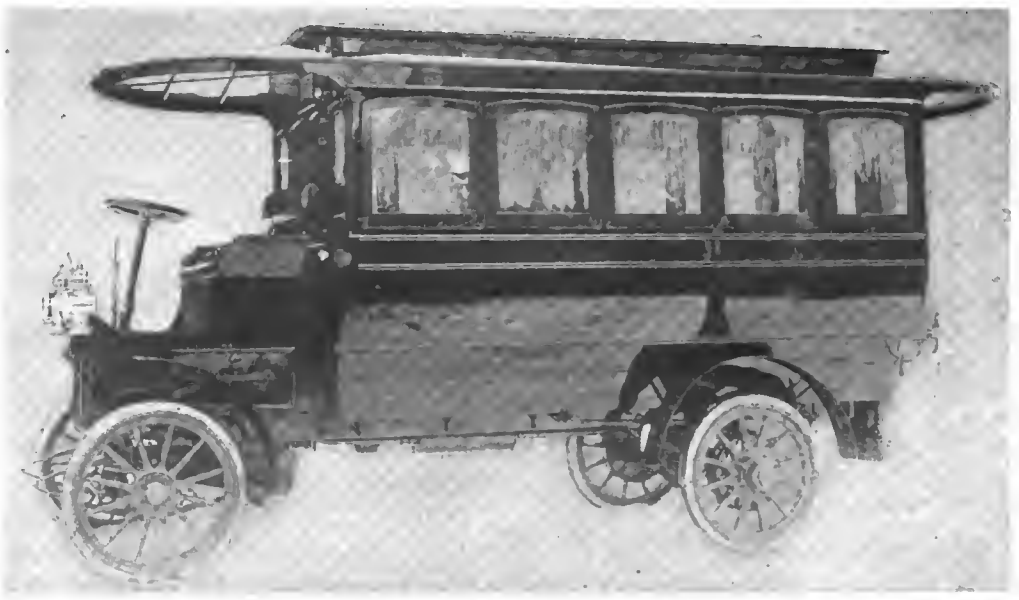
As a mark of confidence in its own product, publicly expressed, the excellent example of long service afforded the Packard Company by its truck number four, is also of interest. This vehicle did the hardest kind of work and was subjected to all sorts of overloads, yet after two years of this, a single coat of paint and simple overhauling is the only reward it will get before being put to work again.

In connection with the recent diatribes of the Senate, against automobiles for transportation, the point has been brought out that this country possesses a smaller number of commercial cars than any European country one might think of. This evidence of backwardness on the part of a nation accustomed to pride itself on the opposite, will only be dispelled by the wholesale adoption of commercial cars. An opening wedge, perhaps, is the recent purchase by the War Department of a car of the light delivery type from a prominent Pennsylvania concern. At any rate, this car and its performance will be closely watched, not only by other departments, but by other manufacturers of this type of car as well. The pointers gained from this installation will be valuable when Uncle Sam is again in the market. Although a poor customer in this line, in time to come he will be a heavy buyer.

The question is often asked: "How long will a motor truck stay in active commission?" An exact reply is impossible because every individual truck operates under different circumstances, performs different service and may have different care. Examples of what some trucks have done, however, show that a good truck is capable of much longer service than ordinarily would be expected. The Packard Motor Car Company, of Detroit, Mich., uses its own three-ton truck exclusively in local hauling. The Packard Company's truck No. 4 was put into service in 1907. It has been actually in service 522 days, during which it has covered 16,489 miles. Its principal work has been in hauling express and freight between the Packard factory and the different railway freight depots. The truck, in the time it has been in use, has made 1,373 trips and has hauled 7,833,022 pounds of freight, or, approximately, 4,000 tons. Its tonnage per day has been 7.5 (15,006 pounds) and its average tonnage per trip 2.85 (5,705 pounds). The gasoline consumed in these 522 days of work has been 3,548 gallons, or on an average of 4.64 miles per gallon. The truck has just been put into the shop for repainting and overhauling, and, as soon as this is accomplished, will be placed again in the regular service.

Replacing Horse-Drawn Herdics in Washington.

A motor omnibus, the product of the H. H. Franklin Manufacturing Company, has been put in service in Sixteenth street in Washington, the plan being to replace with such vehicles the horse-drawn herdics which have been in use in that street despite long complaint on the part of Washington people. The omnibus is specially built to accommodate fourteen or sixteen people, seated along the side. It is for operation without a conductor, the door, at the rear, being controlled by the driver by means of



Franklin Air-Cooled 'Bus in Service on Sixteenth Street, Washington.

The War Department's Latest Recruit, an Autocar.

a strap. Fares are deposited in a cash box of which he is in charge. The car is electrically lighted and weighs 3,180 pounds. It is built on a chassis that is practically that of one of the Franklin trucks, with a lengthened wheel base, 120 inches. It has a worm drive rear axle. The engine is air-cooled and has 18-horsepower. The cylinders are 3⅜ x 4 inches. The vehicle is geared to run about fifteen miles an hour, and is to be in service 17½ hours daily, running in that time 120 miles. It is provided with three speeds forward and a reverse; the transmission is of the progressive type, sliding gear. The body was built by the Ellis Omnibus & Cab Company of Cortland, N. Y., and negotiations for placing the car in service were made by the Cook & Stoddard Company, Franklin dealer in Washington. The omnibus is operated by the Metropolitan Coach Company.

Uncle Sam Takes Delivery of a Commercial Vehicle.

The third illustration shows a car recently delivered to the United States War Department for use at the Frankford Arsenal in Philadelphia. This is a good example of the new Type XVIII commercial car brought out by the Autocar Company of Ardmore, Pa., and although this type is in the nature of a departure for this firm, the happy result is best expressed by such involuntary compliments, coming as the result of a searching inspection of the whole field by the Engineers of the War Department. By an examination of the cut it will be seen that the car is of the type in which the driver is placed over the engine thus shortening the effective length of the car, and what is of even greater value, the wheel-base, which in turn decreases the turning radius. In cities of many narrow streets, this latter is a great advantage as it allows of turning around without backing. The car has the additional time-saving advantage of a unit power plant which is quickly removable without disturbing any other part of the car. Thus in case of trouble, particularly where time is of first importance, the power plant is removed as a unit and another substituted, delaying the car but a small fraction of the time that would be necessary to remedy the damage.

The body is of the box or enclosed type, with rear doors. In addition, the front of the car body is open so that the driver can see the interior at all times, curtains being provided as a protection against inclement weather.

Rutherford, N. J.—Three automobile stages, with a seating capacity of thirty each, have been put into service by the Rutherford Transit Company between the Erie Railroad station and various points in the borough. This company, composed mainly of local residents and stockholders, has been recently formed, with a capital of $2,000, to supply proper transportation to the station, and, with a low rate of fare and fixed schedules, it is thought that most of the 1,500 commuters will use the stages. It has been estimated that it will cost $13,870 to operate the three cars yearly, and that the gross receipts will be $16,425.

TAXICABS AND A FACTORY FOR SAVANNAH.

SAVANNAH, GA., March 1.—Taxicabs on the streets of Savannah will be a reality in the immediate future. Mr. Edward Wilson, while at the automobile show in Detroit, closed a contract for automobiles valued at more than $75,000, among them being six taxicabs that will be seen here as soon as the factory can make the shipment. The taxicabs ordered are of the latest and most approved model.

A convenience such as the taxicabs is bound to be something which the visitors as well as the merchants will not overlook.

Prior to going to Detroit Mr. Wilson visited the motor-boat show in New York, and now that he has seen what the larger cities are doing, has in mind building an automobile factory to begin with a capital of $350,000. Mr. Wilson is the second one who is figuring on a factory here, and it is probable that before the end of the year Savannah will be found with one or more of the largest automobile factories in the United States.

HOOSIERS TO HAVE TAXICABS, TOO.

INDIANAPOLIS, IND., March 1.—A taxicab service similar to that of other cities will be established in this city about April 1. The promoter of the project is Charles W. Sheetes, who has owned a livery stable for several years.

Sheetes is having a concrete garage building erected about one mile from the center of the business district. This will be 42 by 100 feet and will cost about $11,000. He has ordered four Lambert taxicabs and will add to this number later if the demand warrants an additional expenditure.

It is the intention to send the cabs out only on call when the service is first established, but as the number of taxicabs increases, some of them will be stationed on downtown streets for the convenience of transient passengers. While this will be the first taxicab service, the city has had electric cabs for some years conducted by the Bird Transfer Company. This consists of electric cabs which have been stationed at the Union Station, hotels, and held at the garage for special calls.

NEW TRUCK HAS ECONOMICAL ENGINE.

DETROIT, MICH., March 1.—The former head of the Reliance Motor Truck Company, which has just been sold to the General Motors Company, is now busily engaged in the formation of a new concern to manufacture an improved type of truck. Associated with Mr. Paige in the new enterprise are H. A. Wilcox and Andrew Bachle, both technical experts. The new concern will put on the market commercial trucks, as did the Reliance company, but claims to have a new engine, which, while similar in some respects to others now being used, will include several improvements, on which patents have been taken out.

The inventions, which are said to characterize the new motor truck to be exploited by this company, are the results of the experiments of several men.

One of the features will be the consumption of less than one-third of the gasoline usually required. The factory, when it is built, will employ 800 men.

CANADIAN CITIES TO HAVE TAXIES.

MONTREAL, March 1.—A company is being organized, with a capitalization of $2,000,000, to operate taxicabs in Montreal, Toronto, Ottawa, and Winnipeg. An investigation has already been instituted as to the kind of cars that will be most suitable for winter climate. The cabs will cost between $1,250 and $1,300 delivered in the city. They will be of the ordinary type, the operator sitting above and behind. The capacity will be two and four persons.

As to the tariff, which is an important matter, no definite announcement can yet be made, for there is a by-law in force which forbids taxicabs being run for hire in this city. The promoters of this project want this law repealed.

Pierce Pleases Pittsburg's Police.

Seated in the forty-horsepower Pierce-Arrow, recently purchased by the city of Pittsburg for the police department, are Edward C. Lang, Director of Public Safety, at the wheel; Thomas A. McQuaide, Superintendent of Police; Robert P. McCurdy, manager of Banker Brothers Company, and Murray Livingston. Although delivered very recently, the police officials are enthusiastic over their car.

Unusual Fuel Economy.—With all the talk of lower-priced lower-powered cars, the main idea back of it all may be summed up in a single word—economy. This same idea is being carried forward now, and the matter of economy of maintenance is becoming one of large interest. In this respect probably the two largest items are tires and gasoline. The former may not be helped much, but the latter is certainly susceptible to improvement. At one stage in the industry a mileage of eight or nine per gallon of gasoline was considered very good, but of late superior construction has pulled this up to 12, 14 and even higher for an average on long runs, with 20 and higher for shorter runs under favorable conditions. Thus, in the election day contest of many, perhaps hundreds, of Chalmers-Detroit drivers, the prize was awarded for a mileage of 25. Many made 20 and 22 miles. Recently on the coast a century run with six passengers was made in a car of this make on less than five gallons.

No Necessity for a Crane.—If you possess a good car, in particular a good electric, there is no necessity for a crane to hoist anything. The spectacle is often seen of the tedious process of hoisting by means of a horse and a windlass truck. This process is quite too slow for the Lilly & Stalnaker Hardware Company, of Indianapolis, who own a Model 43 Waverley electric delivery wagon. Having a 500-pound casting to hoist to the third floor of the new Y. M. C. A. building in that city the other day, they rigged a block and tackle as if for a windlass, attached one end of the rope to the casting and the other to their Waverley and then started up at first speed. Without a moment's halt, and at a rapid pace, the Waverley moved down the street and the casting up to its place. It was all done in a jiffy, and the lever was not advanced beyond first speed.

Apperson's California Victory.—Further details received upon the victory of Elmer Apperson in the blue ribbon automobile event upon the Pacific Coast, the Pasadena-Altadena hill climb, on Washington's Birthday, show that the performance of the Jack Rabbit this year was even more to its credit than that of last February, which it also won. The hill is a mile and four-tenths long, with an average grade of 11½ per cent., and was covered by the winner in 1:24 from a standing start, an average speed of a mile a minute being attained. In the 1908 event the time was 1:36 1-5, an average of 52½ miles per hour. The trophy is a handsome cut glass bowl, presented by the Automobile Dealers' Association of Southern California. Barney Oldfield was second in his six-cylinder Stearns, in 1:29¼, and a Stoddard-Dayton third, in 1:36 2-5.

New Top Has Novel Feature.—At present the enclosed body holds sway, but very soon the open touring body with folding top will be in demand. Anticipating this, limousine bodies designed for touring over a protracted period of time have many novel features. The latest of these, a top that is practically removable, is found in the 50-horsepower Isotta-Franchini which Lewis A. Riley, president of a big Philadelphia transportation company, purchased from J. M. Quinby & Co., of Newark, N. J., the limousine body being made by the same firm. Mr. Riley has planned an extensive tour abroad for this coming season in his new car, and when in mountainous country can have part of the top rolled back, thus permitting an unobstructed view of the mountain peaks which tower above in every direction.

Packard Will Use Shock Absorbers.—Time was when the necessity for any form of shock absorber was not granted, but had to be proven, being a disputed point. To-day the opposite view holds, in that all of the best cars are fitted with a form of "jolt" preventer. This right-about-face has taken place in the last three years, and, although gradual, is none the less permanent. The announcement, therefore, by the Hartford Suspension Company that for 1910 every Packard automobile will be equipped at the factory with the Truffault-Hartford shock absorbers does not come entirely as a surprise, but as a further evidence that automobile manufacturers as a whole are appreciating that anything they can do to make their cars ride easier and give better satisfaction is money well invested.

Hagstrom Company Increases Stock.—An increase in its capital stock from $50,000 to $150,000 has been voted upon favorably by the stockholders of the Hagstrom Bros. Mfg. Co., of Lindsborg, Kan., manufacturers of the Hagstrom patent inside blow-out patch and other specialties. The directors of the firm are William Hagstrom, president; Emanuel Hagstrom, secretary; Gustaff Hagstrom, treasurer; N. J. Thorstenberg, vice-president, and A. A. Abercrombie, Gust Eskwall and A. E. Agrelius. Plans for extensive additions and alterations around the factory have been made, including the building of a garage and salesroom, where the agency for a number of medium-priced cars will be placed.

Light Delivery for Library.—Following the example of the Chicago and other large libraries, the Minneapolis institution will hereafter be served by a gasoline vehicle. Kemp Brothers, agents for the Brush runabouts and package wagons, have recently closed a contract for a light delivery wagon to be used in the delivery service of the public library and its branches. This deal was put through after several convincing demonstrations had been made of the ability of the little wagon to waltz through the heavy drifts of snow and rough going now found in all sections of the city. The little wagon did the work of two horses and saved nearly 50 per cent. of the time in so doing.

Diamond Tires On White House Cars.—The makers of Diamond tires, according to C. B. Myers, of the factory, are well pleased with the representation which this make has received lately from officialdom in Washington. Mr. Myers says, "We have the equipment on the cars to be used by President Taft at the White House, on Speaker Cannon's personal machine, and also upon the Peerless limousine which was exhibited in the Cleveland show and has since then been shipped to Washington for Vice-President Sherman. On this car we have also marsh rims with quick-detachable tires."

First Show at San Jose.—Following the larger cities, the smaller towns are being infected with the show microbe. The latest to "take" out on the Coast is San Jose, which held its first automobile show recently. Previous to the opening a street parade was held, in which not less than fifty cars participated. For the exhibition the Auditorium Rink was utilized, but even this was insufficient, in view of the crowds attending. Considering that this was a first "offense," that sort of a reception was particularly gratifying to the promoters and assured the annual continuance of the affair.

New Toledo Company to Build Electrics.—The Ohio Electric Carriage Company, to build electric automobiles of the coupe style, has been formed by prom-

inent Toledo business men. Options have been taken on two or three factories here, but it is likely than an entirely new plant will be erected to produce the car, which will be known as the Ohio. H. P. Dodge, who has been a leading spirit in the preliminary work, will be the general manager, and incorporation papers are now ready to be sent to the Secretary of State.

A Pertinent Correction.—Talk about geography made to order. In the hurry of getting out a big issue like that of February 11, relative to the Chicago show, firms are sometimes inadvertently shifted from one town to another. Sometimes, too, this does not please, strange to say. For instance, in the issue mentioned above we moved the W. H. McIntyre Company to South Bend, Ind. Now it seems that this company do not like that town, so we hasten to move them back to Auburn, Ind, where they were before we started to experiment with the map.

Hartford Shock Absorbers at New Orleans.—Truffault-Hartford shock absorbers have figured in more races and record-breaking trials during the recent Mardi Gras automobile race meet at New Orleans. They were the equipment of the Fiat *Cyclone*, which made the ten-mile track record, and won a considerable number of all the events, and they were used also upon the Knox *Giant*, which Mrs. J. N. Cuneo used, and with which she won a number of events and always figured well up among the finishers.

Touring in Cuba.—That the term of office of Governor Magoon, who has just returned from Cuba, had a good effect upon the roads of the island is well shown by the number of American auto enthusiasts now making winter trips over the ideal highways. Governor Magoon changed them from cart paths to 60-feet wide macadam roads, and one of the number now touring over them is Dr. Munyon, of Philadelphia, in a Lozier limousine.

New Metropolitan Supply House.—The Weaver-Ebling Automobile Company, composed of Raymond H. Weaver, who was formerly with the supply department of Wycoff, Church & Partridge, and R. W. Ebling, of New York City, has been formed to carry on a business in automobile supplies. A full line of all kinds of sundries will be handled from the firm's location, on Broadway at Seventy-ninth street, New York City.

A. M. T. A. Elected Officers.—The board of directors of the Automobile and Motor Trades Association, a Rochester, N. Y. organization, met recently and elected officers for the ensuing year. These were the men chosen: President, John A. Breyfogle; vice-president, William S. Graham; secretary, Frank Peck; treasurer, Sidney B. Roby. A meeting will be held shortly, at which President Breyfogle will announce his committees.

Auto Races for York, Pa.—J. Allen Heaney, an inventor of York, Pa., is arranging plans for a number of local race meets, both on track and road. The first would be a speed contest of 50 or 100 miles on roads leading to York with a prize of $100 to the winner. A second race of 15 or 20 miles will be held upon the track of the York County Agricultural Society, while the third has not as yet been decided.

Will Build to Order.—Nilson-Miller Co., of Hoboken, N. J., recently incorporated with a capital of $25,000, is located at 1300 Hudson street, in the shop formerly occupied by W. D. Forbes & Co. and will conduct an engineering and general machine shop business, making a specialty of designing and building, to order, electrical apparatus, gasoline engines, etc., for commercial vehicle, marine and stationary use.

Walter Plant Will Make Roebling Cars Only.—At a meeting of the Walter Automobile Company held last week at the East Trenton, N. J., plant, it was settled that the Roebling-Planche car exclusively will be built at this works. A number of hands were taken on and the cars as shown at the Garden show will be turned out in larger numbers.

IN AND ABOUT THE AGENCIES.

New Agencies for York Pullman.—H. R. Averill salesagent for the York Motor Car Company, the manufacturers of the Pullman automobiles, has returned to the factory after a two-months' trip around to various automobile shows and reports the establishment of agencies in the following cities: Chicago, Ill.; Topeka, Kan.; St. Louis, Mo.; Louisville, Ky.; Cleveland, Ohio; Cincinnati, Ohio; Indianapolis, Ind.; Dallas, Tex., and New Orleans, La. Later a branch house will probably be opened in Chicago. The factory is now running night as well as day to fill orders.

Stoddard-Dayton's New York Home.

The illustration shows the new home of the Stoddard-Dayton in New York City. The building is located on Fifty-seventh Street, near Broadway, next door to the old store.

Elmore, Philadelphia.—Elmore popularity in Philadelphia and the East is signified by the recent acquisition by Gawthrop & Wister, the Quaker City agents, of a large subsidiary establishment at 223-225 North Sixteenth street, which will be solely devoted to garage purposes, the "Row" quarters at 244 North Broad street to be used hereafter only as salesrooms for the rapidly growing local business. In addition, W. W. Gawthrop, who is Elmore sales manager for the Atlantic coast States, has established a main sales office in the Bulletin building, opposite the City Hall.

Remy Magnetos, Chicago.—A branch distributing house has been established at 1400-1402 Michigan avenue, Chicago, under the management of Major B. Hawxhurst. An expert magneto mechanic will be sent from the factory to assist Mr. Hawxhurst and the company will be prepared to install magnetos on old cars. The Remy Electric Company opened a branch distributing office in New York some time ago. The demand for Remy motor ignition systems has resulted in the factory and office forces being almost doubled as well as new agencies established.

Factory Sales Corporation, Chicago., has taken on as an addition to their present line of accessories, the product of the New York Coil Company. This comprises both high and low tension coils in all the various forms applicable to automobile, marine and gasoline engines, also a special motor-cycle coil and wireless telegraph coil. A specialty is a multiple coil with master vibrator for use in connection with low-tension magneto, although it is equally applicable to battery service.

Renault, Chicago.—Owing to a large increase of business in Renault cars handled in Chicago, the Renault branch has arranged to have a building erected for it at 1606 Michigan avenue, with large showrooms, repair shop and spare parts department. During the Chicago show Mr. Lacroix received from the Auto Taxicab Company, which operates the Renault taxi service, an order for thirty more cabs.

Moline Agencies.—The Moline Automobile Company, of East Moline, Ill., has appointed these new agents: Cambridge, Ill., P. A. Johnson; Monee, Ill., George S. Miller; Joliet, Ill., O. S. Viner; Walcott, Ia., J. H. Strohbeen; Coffeeville, Kan., Isham Hardware Company; Bloomfield, Neb., Bloomfield Auto Company; Santa Fé, N. Mex., O. W. Alexander.

Fisk Tires, Philadelphia.—The Bergdoll Company, which is operating thirty taxicabs in Philadelphia, has just closed a contract with the local Fisk representatives to equip all their cabs with 32 by 4½-inch Fisk tires. The Bergdollites have figured that this size tire gives better service on taxicabs than anything larger or smaller.

Mitchell, Pittsburg.—The Pittsburg Mitchell Company is the name of the new firm that will handle the Mitchell cars in this city. The new firm is composed of A. X. Phelan, a well-known Pittsburger, and R. L. Flynn, formerly with the Mitchell agency at Washington, D. C.

Morgan & Wright, New York City.—The business of selling "good tires" has increased so that Morgan & Wright of New York have been compelled to move from their old location at 214 West Forty-seventh street into more commodious quarters. They are now at 1849 Broadway.

Lozier Agencies.—Three new agencies for Lozier cars have been established, in line with a policy of moving into Western territory. They are: Horicon, Wis., Williard V. B. Campbell; Franklin, Pa., Franklin Motor Car Company; Columbus, O., Samuel A. Esswein, 24 West Broad street.

Reliable Dayton, Memphis, Tenn.—A branch house, office, repository and salesroom has been opened at 335-337 Poplar avenue, Memphis, by the Reliable Dayton Motor Car Company, of Chicago. At the opening held recently a large amount of business was done.

Midland, New Jersey.—The agency for the Midland car, made in Moline, Ill., has been taken by E. K. Conover, of Paterson, N. J. Mr. Conover will have the entire State as his field, and from salesrooms in Newark and Paterson will establish sub-agencies.

Continental Tires, Kansas City, Mo.—The list of distributors of Continental tires and tire materials has been augmented by the addition of the Columbus Buggy Company at 810-14 Walnut street, who will have the states of Missouri and Oklahoma.

Trojan Tires, Philadelphia.—The Philadelphia Rubber Tire Company, 680 North Broad street, has taken the local agency for Trojan clincher and solid tires. Samuel Levy, formerly of the Philadelphia Auto Tire Repair Company, is manager.

Matheson, Rauch & Lang, Denver.—F. S. Vreeland is at the head of a new firm formed to handle the Matheson gasoline and Rauch & Lang electric cars in Denver. Headquarters have been secured at No. 1643 Court place.

Petrel, Chicago.—R. D. Loose, who has the Chicago agency for the Pittsburg "Six," has added the Petrel, a moderate-priced car made by the Petrel Motor Car Company, of Kenosha, Wis., to his list.

Jewel, Chicago and Toledo.—New agencies have been established in the West by the Jewel Motor Car Company as follows: Chicago, S. H. Peterson & Company, 1229 Michigan avenue; Toledo, O., Standard Garage Company.

Nadall, Detroit and Columbus.—The General Sales Company of Detroit has taken the sole representation for the Nadall product. In the future this concern will be represented in Columbus, O., by the Curtin-Williams Company.

Apperson, Pittsburg.—The agency for the well-known Apperson line, including the famous Jackrabbit, has been taken by Wainwright & Bratton, proprietors of the Pittsburg Automobile Hospital.

Columbus Electric, New York City.—The famous firm of horse dealers, Fiss, Derr & Carroll, have opened an automobile department and are the Eastern distributers for Columbus electrics.

Great Western, Chicago.—The Great Western Motor Car Company, the local agent for the Great Western cars, has moved its office and salesroom from 1325 to 1253 Michigan avenue.

Reo and Kisselkar, Beloit, Wis.—George F. Beedle and Allen Daerhammer have formed a partnership to handle in Beloit the Reo and Kisselkar.

Maxwell, Columbus, O.—G. J. Stark and R. F. Baker, composing the firm of Stark & Baker, have taken the agency in Columbus for the Maxwell.

National, Columbus, O.—Robert Boda has signed for the National agency in Central Ohio.

SOME BUSINESS TROUBLES.

New York Car and Truck Company.—Schedules in bankruptcy of the New York Car and Truck Company, manufacturer of automobiles and car trucks at Kingston, N. Y., of which Orlando F. Thomas of New York, was president, show liabilities of $496,580, of which $309,603 are secured, $7,171 for taxes, and $2,829 for wages, and nominal assets of $2,821,742, consisting of factory property and plant, $2,500,000; actual value unknown, mortgaged for $308,000; stock, $86,558; accounts, $11,885; notes, $2,450; cash in bank, $724; office furniture, $125, and shares of stock in other corporations, $220,000. Among the creditors are the Morton Trust Company, $220,000, secured; Trust Company of America, as trustee for bondholders, $20,000; secured; Hudson Trust Company, $20,000; Consolidated National Bank, $72,239; Robert Bernard, $7,000, secured; H. G. Lewis, $6,000, and T. J. Lewis, $6,000.

Cadillac Automobile Company, Indianapolis, Ind.—A fire, starting from an explosion of gasoline, destroyed 14 machines and gutted the building occupied by the Cadillac Automobile Company, 23 East Ohio street. The loss on the building was about $1,000, while the contents were valued at $17,000.

Rainier Motor Car Company, New York and Saginaw.—Schedules in bankruptcy of this company show liabilities of $299,355, as against nominal assets of $283,818. There are also unliquidated claims for damages aggregating $89,292, the actual value of which is unknown.

Crescent Motor Car Company, Chicago.—E. C. Buell was recently appointed receiver of the Crescent company, following the filing of a petition in bankruptcy by its creditors. According to the latter, the liabilities aggregate $10,000, while the assets are only $6,000.

F. F. Goodman, New York City.—Schedules in bankruptcy of Frederick F. Goodman, Inc., conducting an auto garage at 53 West 93d street, show liabilities of $14,000 and nominal assets of $5,476.

RECENT BUSINESS CHANGES.

American Distributing Company, Indianapolis, Ind.—After March 1 the American Distributing Company, formerly of Cleveland, will be located at 207 West South street, Indianapolis, from which point it will continue to act as exclusive sales manager for the Westinghouse Electric & Mfg. Co., Hayes Wheel Company, Lewis Spring & Axle Company, Jackson Drop Forging Company, American Gear & Mfg. Co., Elyria Machine Parts Company, Kinsler-Bennett Company and the Sparks-Withington Company.

Jones Speedometer, Hartford, Conn.—Temporarily, the Jones speedometer is without an office in Hartford. On Tuesday, February 25, fire rendered its branch at 284 Trumbull street, in that city, uninhabitable for the time being, and pending repairs the New York City headquarters will take care of the Connecticut trade.

Morgan & Wright, New York City.—Owing to the large increase in business, the Metropolitan branch of this Detroit rubber house has been compelled to move from its old location to more commodious quarters, at 1849 Broadway, right in the heart of automobile row.

Foss-Hughes, Baltimore.—The Foss-Hughes Motor Car Company have leased the large store at 533 North Howard street, where the salesrooms for the Pierce Arrow cars will be removed as soon as the extensive repairs now being made are completed.

Providence, R. I.—There has been a change in the personnel of the Dauer Auto Company. George E. Foster is now secretary and treasurer, while W. S. Achorn will act in the capacity of manager. The Franklin agency will be retained.

Boston, Mass.—The Ajax Tire Company, Boston branch, has moved from Boyleston street to Park square, near the Motor Mart. C. H. Cooper is the local manager.

C. W. Leavitt & Company, New York City.—After March 20 this firm, dealers in ores, metals and alloys, will be located in the Hudson Terminal, at 30 Church street.

PERSONAL TRADE MENTION.

Harry S. Howlett, who has been identified with some of the largest tire manufacturers in the New England States, has assumed charge of the Jones Speedometer office in Boston. Manager Howlett will promote the Jones interests throughout the New England territory, where he is well and favorably known in the trade. He was formerly engaged with the Diamond Rubber Company, and more recently with the Fisk Rubber Company's Boston branch.

Mr. and Mrs. Firestone Go South.—President H. S. Firestone, of the Firestone Tire & Rubber Company, accompanied by Mrs. Firestone, left Akron this week for a journey to Southern lands, to be gone until April 1. After some days spent in New York, at the Firestone agency at Havana, Cuba, and other points in that island, they will return to Miami, Fla., and sail from there to the Bahamas, returning in time for the speed contest at Ormond and Daytona beaches.

J. Stewart Smith, formerly with Emil Grossman, now as general manager of the Standard Sales Company, has opened New York City offices at 1779 Broadway, at Fifty-seventh street, as successor to the T. C. & W. L. Fry Company, handling the Fry magneto and spark plug.

Ralph P. Dowse, of Chicago, has succeeded to the position of manager of the Detroit branch of the G. & J. Tire Company, taking effect March 1. He is well acquainted in the trade and familiar with the G. & J. tire, having spent several years on the road for that company.

Evans C. Church, who for several years has held the position of assistant manager at the Philadelphia White Company branch, has succeeded Max R. Greene as manager. The latter goes to New York, where he will join the sales force of the Carl H. Page & Company.

L. G. Nilson has been elected president of the Nilson, Miller Company, 1300 Hudson street, Hoboken, N. J. Mr. Nilson was formerly chief engineer for the Strang Gas Electric Car Company and will continue to act for the company in an advisory capacity.

C. J. Connolly is now on the sales force of the Mutual Auto Accessories Company, and will cover the territory formerly covered when he was on the traveling force of the Motor Car Equipment Company.

F. L. Fuller, manager of the Philadelphia Chadwick branch, is back at his desk after a season of recuperation at Atlantic City from a severe attack of typhoid fever.

Charles A. Monson has accepted a position with the Gray & Davis Lamp Company. He was formerly with the G. & J. people as manager of the Detroit branch.

RECENT TRADE PUBLICATIONS.

Pope Manufacturing Co., Hartford, Conn.—The Pope-Hartford catalog has 24 pages. The cover, a masterpiece of its kind, was designed by Thomas Sindelar of New York City. The design represents a female figure draped with a veil, holding in the outstretched left hand a Pope-Hartford car and in the right, a palm branch. The idea conveys speed, the face showing excitement and the veil, motion. In the distant background are factories. The whole is printed in black on rhododendron telanian blue paper with high lights in white and background in gold. The inside illustrations are printed from due tone plates, black over buff, the resulting effect being of a highly artistic and pleasing nature. There is a handeome sub-cover and the inside pages are of "superfine" paper. The treatment of the subject-matter consists of the use of full pages for the complete cars, showing the various touring car, roadster, pony tonneau, and enclosed bodies, while detailed cuts scattered through the opposite pages cover the mechanical features. With the exception of the engine, these are small, but this important part of the car is given nearly two whole pages. By using cuts of this large size, the essential features are made very prominent, allowing a close inspection. Not the least interesting portion of the book is the last section devoted to commercial cars. There both the police patrol and ambulance are pictured and well described also.

H. H. Franklin Mfg. Co., Syracuse, N. Y.—In the wonderfully improved press work being used in the newer catalogues it is hard indeed to select any one feature that stands out more prominently than the others. The 1909 book of Franklin Motor Cars is a striking example of this. Carried through the book is a border effect in very soft tones, these borders being a series of different rural scenes, starting with a broad, tree-lined, winding drive up to a palatial country home and ending with just a glimpse of a car, a Franklin naturally, going in a garage. The numerous illustrations depict the parts and features common to all Franklin cars, together with thie coming season's line of bodies. The newer details are an X-ray picture of the steering gear, the magneto, oiler, wood frame and clean dashboard. Four full page color plates showing the Franklin "en tour," at a polo game, hill climbing in the fall of the year and the closed car in winter source, increase the artistic effect.

Badger Brass Mfg. Co., Kenosha, Wis.—This new catalogue covering the 1909 product is distinctive in that, aside from the cover, all of the artistic trimmings usual to these are omitted so that the work is a short very business-like mention of the articles manufactured with all of the usual superlative boasting left out. A few pages at the front are devoted to a clear exposition of the Bresnard system of light projection and eclipsing for which this concern has the exclusive rights. Of pleasing appearance to the motorists who do not keep a chaffeur as well as the chauffeure themselves, is the new black patent leather finish. This is impervious to heat and moisture, besides heing fully as durable as any body finish. Mention is also made of the short focus mangin mirror reflectors used on all of the hetter lamps. An insert sheet describes the new motorcycle headlight recently produced.

The White Company, Cleveland, O.—Bulletin 13, just off the press, the cover of which we show herewith, is as might be judged by the cover, rather an exposition of the factory methods and men behind the car than a catalogue. Insert cuts liberally scattered through this 26-page booklet ehow scenes in the new shop buildings, machines and groups of machines both idle and at work. These little side lights on a famous product show that there is nothing to hide, even the daily work and the machines that do it heing a source of pride. Not the least of the cuts is one of the locker rooms showing the wash-stands. This is right in line with the betterment work being done by all of the larger factories for their own good incidentally, and that of the men directly. A capahle description of the plant by R. T. Clegg smplifies the pictures.

National Tube Company, Pittsburg, Pa.—This is really not a catalogue but a description of the process of making Shelby steel tubing. The illustrations are fine on a very heavy book paper and illuetrate in full detail the principal operations through which a billet of open-hearth steel passes on its way to become a seamless cold-drawn steel tube. Beginning with the view of a pile of steel billets, the process is followed through the centering, piercing, sawing, hot rolling, pointing, cold drawing, and annealing processes. The finished etock, the various shops, and many of the smaller details are expanded and illustrated, also. A very simple and right-to-the-point diecuseion or write-up of the whole procese amplifies the pictures.

Moline Automobile Company, East Moline, Ill.—The car for anywhere, the Moline Models K and M for 1909, are described in full in the new catalogue. A very attractive heavy brown cover with the word "Moline" in large white raised letters houses it, while between the catalogue and the cover is an attractively designed sub-cover green upon brown. The text in green type with black sub-heads describes the detailed features of these two models, considerable space being devoted to the unit power plant and three-point suspension idea, featured in both. Following the modern trend toward commercial wagons, Model M is also fitted with a light delivery body in place of a tonneau.

Moon Motor Car Company, St. Louis.—The attractive design shown herewith covers the 1909 catalogue of Moon cars. The feature of this is the use of the outlines of the lamps as the two "o's" in the name of the car. The subject-matter itself is equally as attractive as the cover. A very common sense feature appears in thie for the first time; namely, the division of the subject-matter into two parts, the first being the general non-technical write-up, and the second the technical description. The larger illustration shows the bodies and completed cars, prominent among which is the new Brevette body, while the smaller cuts illustrate the various units and parts.

Fisk Rubber Company, Chicopee Falls, Mass.—A slightly different catalogue under the name of "Cup Winners. 1908," shows some very effective and tasty press work. The center of each page, the only portion printed upon, ie of white and the type black, but the border of each page is of a buff shade. The wide border and different color make the central portion of the page etand out very distinctly. The text refers to the records of the Fisk bolted-on tires and removable rims in hill, road, and track contests during the past season, which the illustrations amplify. Among the interesting photos are the Knox and Thomas Vanderbilt racers.

Stevens-Duryea Company, Chicopee Falls, Mass.—In a small 6x9 catalogue of 32 pages this company has presented in concise and ready reference form the details and specifications of the various models now produced. The six-cylinder constant torque engine is dwelt upon briefly, as is also the unit power plant and three-point support. The four models for the coming year are the big and little "six," continued from last year, and a new "four," larger and more powerful than last season's Model R. Not the least interesting thing in the book is the list of twenty rulee for automobiles by Dave Hennon Morris, reproduced in the back of the book.

New Departure Mfg. Co., Bristol, Conn.—The latest catalogue from the press of this firm is a new departure in itself. Besides exploring every possihle feature of the New Departure two-in-one hearings by very interesting pictures and well written text, all of the mechanical statements made are proven in foot notes. The latter are written in as simple language as is possible to use and prove the point so that the book will be of equal interest to the technical man or designer and the layman with little knowledge of technical points. The illustrations are well chosen to illustrate the point named.

Continental Caoutchouc Company, New York City, is distributing a book relative to Continental Ready-Fisted tires, the method of treatment in which is unique. On one page will be found photographs of two letters of recommendation, while unon the opposite page will he found photographs of the two cars in question plainly showing the Continental tires in place. These include many racing cars prominent in the Brighton Beach and Briarcliff races, as well as the new fire-wagon for the Detroit Fire Department. The whole makes an excellent and convincing exposition.

Reliable Dayton Motor Car Co., Chicago.—The first real successor to the horse is the statement or rather the phrase used on the title of this hrown cover booklet. The remaining 23 pages are devoted to proving this as well as incidentally enlarging on the good features of construction used in this motor buggy. An insert folder labelled "Pictorial and Written Evidence," has some very cunning pictures of the Reliable Dayton acquitting itself well in bad places, such ae hub deep in the mud, through 18 inches of water, deep sand, etc.

Apple Electric Company, Dayton, O.—Bulletin 3 describes the Apple ignition and lighting system, and Bulletin 4 portable storage batteries. In the former the dynamo-floating storage battery ignition system is illustrated by line diagram and cuts of the parts, which conelet of the dynamo, volt ammeter and storage battery. The second bulletin goes into the details of the battery. Thie is so made as to be acid proof both outside and inside.

The Cameron Motor Company, New York City, sales agent for the Cameron air-cooled car, is distributing a large folder descriptive of their 1909 lines. Thie includes four models with the usual line of bodies and varying in price from $900 for the Model 14 four-cylinder runabout, to $1,500 for Model 11 six-cylinder touring car. The air-cooled motor is illustrated and described in full, as is also the patented transmission, which allows of direct drive on all speed.

Goodyear Tire & Rubber Company, Akron, O.—This 9 by 12 pamphlet is not exactly a catalogue, but rather an expansive exposition of the idea pictured on the cover. Thie is in the nature of proof of and reasons for the statement, "We need the dealers and the dealers need us." The air-bottle, red seal inner tube, universal rim, and other features shown on the cards are enlarged upon in language that should be very persuasive to the dealer contemplating a move or a change in this line.

Columbia Lubricants Company, New York City.—A pocket-sized book of 32 pages is offered as "evidence" of the reliability and efficiency of Monogram oils. This is a series of pictures of famous races and equally famous drivers with commendatory letters from the latter relative to the performance of "Monogram" in these races. A couple of new pictures of the Savannah course, Robertson driver of the Vanderbilt winning Locomobile, and others are of live interest.

The Waverly Company, Indianapolis, Ind., is sending out a neat little booklet descriptive of the Waverly electric carriages. This is 5x6 in size, printed on a heavy book paper, and covered with blue on which the gold letters stand out very effectively. The full line as described is too extensive for mention here, so it will suffice to say there is a car for every need. The driving system, the controller, and some other mechanical features are lightly touched upon.

Olliver & Worthington, San Francisco, Cal.—The special pocket edition of the 1909 catalogue of automobile and motorcycle supplies is 4x9 in size, designed to slip in the side pocket. This firm handles Merkal motorcycles, Breeze carbureters, Champion ignition supplies, and the product of many other prominent accessory and part manufacturere, on the Western coast. The catalogue itself of 112 pagee describes these products in detail.

Eck Dynamo & Motor Company, Belleville, N. J., is responsible for a flexible leather-covered catalogue of pocket size with provision for additional eheets. Those included within the covers for present distribution are descriptive of the d.c. dynamos and motors built by this firm. Other leaflets up to 54 in number describe the company's other products, which are converters, fans, switchboards, and other similar electrical products.

R. B. F. Ball Bearings.—The International Engineering Company of New Jersey presents the 1909 catalogue of the Société Française Des Roulements A Billes, whose radical and thrust ball bearings sell in this country. Tables of sizes in both millimeters and inches are given, as well as instructions for mounting and a very complete table of equivalents. This firm also has the agency for the well-known Lemione products.

Gaeth Automobiles.—Pictures have been made to tell the story of the Gaeth, the cover of the pamphlet issued under the title of "Advance Showing, 1909," having its front cover appropriately illustrated with a view of the Gaeth entry in the last A. A. A. tour, while its perfect ecore certificate is reproduced on the back. The contents consists largely of illustrations of the different Gaeth models.

Stromberg Motor Devicea Company, Chicago, is distributing a simple little leaflet showing Type A&B carbureters in view and in cross section; the latter explaining the detailed construction of these very successful devices. Both types are fitted with glass foot chambers, venture shaped internal walls for the vaporizing chamber and other distinctive Stromberg features.

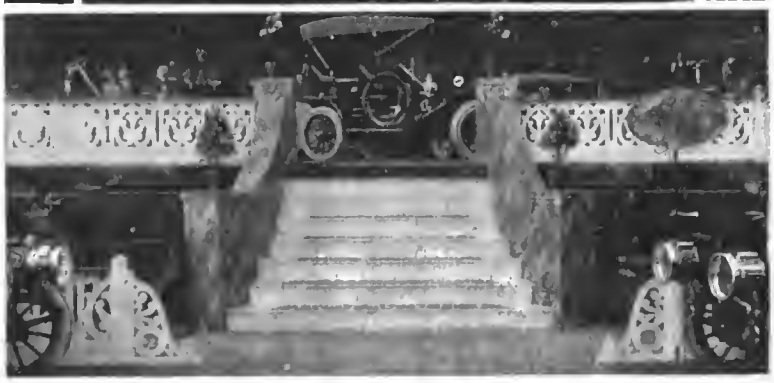
The Empire Automobile Tire Co., Trenton, N. J.—This is a calendar which is being distributed gratis to the trade. The design is an Empire tire in black upon a pure white ground. Within the tire is a large pure white cat, the lettering being "nine lives. Empire tires wear longest." It is an unusual and effective piece of advertising.

Patterson, Gottfried & Hunter, Ltd., New York City, dealers in machinery hardware, tools and supplies have recently issued a new catalogue of automobile tools, a copy of which may be had from them for the asking.

VOL. XX NEW YORK—THURSDAY, MARCH 11, 1909—CHICAGO No. 10

THE AUTOMOBILE

BOSTON'S BRILLIANTLY SUCCESSFUL SHOW



BOSTON, March 10.—This city's automobile show success is always spelled with a big S, and this year is no exception to the rule; if anything, the present show so far has exceeded all its predecessors in attendance and business transacted, and everybody who has space is optimistic over the interest that has been demonstrated since the exhibition began. On the opening night there was a tremendous attendance; as many people crowded into the building as it possibly could hold. Aisles and spaces were so thronged that it was next to impossible to see anything, and it is estimated that more than 40,000 people passed the ticket takers. First-night attendance, however, signifies little except general public interest, and the sales which were reported were mostly those which had been worked up to the signing point before the show began.

With the first of the week, however, began the real business of the show, and it was apparent Monday that all previous records would be broken, for there was a heavy attendance from the time the doors opened, and all day long the salesmen and demonstrators were kept hustling with prospects who took a genuine interest in the cars. Reports of sales were made with unusual frequency and with more ring of genuineness than is customary. Not a few exhibitors have already secured customers for all the cars they have on exhibition, and have taken orders for many duplicates. Even those concerns which have come to the Boston show with new cars, not previously exhibited here—and there is a larger number than in any former year—are well satisfied with what has been accomplished thus far, and are encouraged as to the business outlook for the spring season. There seems every reason to believe that any make of car which can demonstrate reliability and good riding qualities will not lack for patronage this season in New England.

The Efficient Corps of Pages that Was Uniformed in Scarlet and Black.

Boston usually has some novelties to offer, and this time they are very plentiful. There is a compressed air car, for instance, a decided novelty that has not been exhibited elsewhere. This machine has a two-cylinder air-cooled horizontal engine in front, combined with which there is an air compressor and a superheater. The superheating is accomplished by means of the exhaust and the superheated compressed air is delivered to a four-cylinder air motor which in turn drives the car. The advantage claimed for this method of operation is economy and the absence of such complications as gear transmission and clutch. The air motor is used for braking purposes, but the car also has an emergency brake as a part of its equipment.

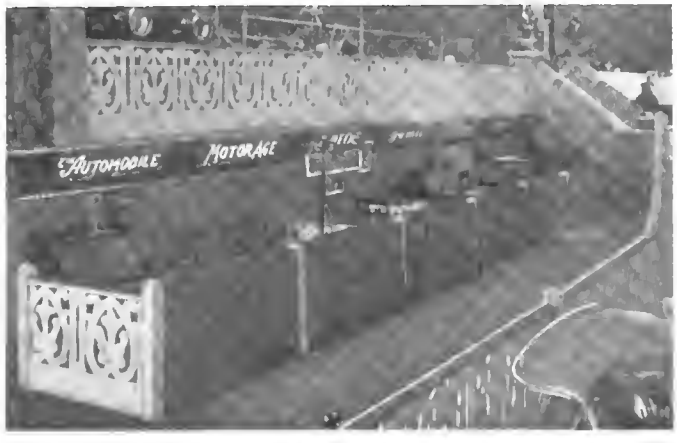
Another new car is the Panther, a little single-cylinder machine listed at $300 and equipped with a disc clutch and gear drive. The Jewel is a third new machine in Boston. This car has a single two-cycle cylinder rated at 10 horsepower and is listed at $500. The Pickard, Herreshoff, Hupmobile, Velie,

Taking in the Exhibits from Rear of Mechanics' Hall.

American Simplex and Brownie cars are also newcomers to this city. Then there are a number of cars, which were shown in New York but which have not previously been shown in Boston, such as the Inter-State, Oakland, Lancia, and Pittsburg Six. An unofficial count puts the total number of different makes of cars on exhibition at eighty-two, which is believed to be a record for any show in the country. The representatives of these eighty-two makes are exhibiting about two hundred and seventy-five separate cars, the count including chasses and all the different types of pleasure cars.

In popularity of type the standard touring car easily leads, and it is a noticeable fact this year that the exhibitors are putting the five- and seven-passenger touring cars in the conspicuous places of the spaces, instead of featuring the toy tonneaus, baby tonneaus, double rumbles and other fancy styles. Next to the touring cars the roadsters are popular, but practically every exhibitor states that the larger number of show visitors is looking for cars that will carry the whole family rather than for sporty vehicles. The Boston show is a little late for enclosed bodies, so there are not as many limousines, landaulets and town cars in evidence as there were at some of the previous shows this season, but in quite a few exhibits there are some handsome enclosed bodies. One of the most striking of these is that ordered by the actor, Nat Goodwin, for his bride. It is on a six-cylinder Welch chassis and is an enormous affair equipped with bath tub, bunks and all sorts of conveniences to enable its owner practically to live on the road.

In every department the Boston show is larger than ever before, and this is especially true of the commercial vehicle section in the basement. The commercial vehicle is experiencing what is expected to develop into a good-sized boom in this city, and the manufacturers and agents are aware of the possibilities in this direction and have put on view an exceptionally fine lot of vehicles ranging from a light delivery wagon to immense five-ton trucks. Not a few of these vehicles are to be delivered to local houses as soon as the show is over, and the names of these concerns on the trucks is somewhat of a revelation in the way the commercial automobile is being taken up. One of the best exhibits is that made by the Rapid, consisting of a large number of complete vehicles and chasses. The Studebaker Company, D. P. Nichols & Co., General Vehicle Company and Knox are also large exhibitors in this section. The motorcycle division is more extensive than it has been in other years, more different makes of the two-wheelers being shown than were exhibited at either of the New York shows.



Where the Leading Trade Journals Were Quartered.

Every year the accessory division grows, and Manager Campbell had difficulty in taking care of all who wanted show space this year. He drew a line against all applicants unless their goods were actual accessories, but even at that all the balcony spaces and not a few in the basement are occupied. The tire exhibits are larger and more numerous than has ever before been the case in Boston, and practically every leading manufacturer of speed-measuring instruments, oils, shock absorbers, lights, warning devices and the like, has space, and all claim to be well satisfied with the attention their exhibits are receiving from the show visitors. Even those exhibitors who by force of circumstances were crowded away into the most inaccessible corners say that people are seeking them out and are taking extraordinary interest in what they have to show and say—all of which demonstrates that the New England public is not only auto-wise but auto-enthusiastic.

There is a very good representation of foreign cars at this show, though the New York importers have not given the Boston exhibit as much attention as they do customarily. The Fiat has the finest display of foreign machines that has ever been made here, with the Lancia a close second. The Renault has an excellent showing of cars, and the Panhard branch is exhibiting two machines. The new American Napier, which is being turned out by the reorganized Napier Company of America, attracts a good share of attention. Very little has been heard of this car for a year or more, but it is said that the company is now in a position to go ahead and manufacture machines in quantity.

Manager Campbell is looking forward to closing the show next Saturday night with a larger net profit to the credit of the Boston Dealers' Association than at any of the previous six shows given here under its auspices. The first of the week attendance is largely from Boston and vicinity, but before the week ends, with continued good weather, there is every probability that there will be a very large throng of people from Maine, New Hampshire, Vermont and western Massachusetts.

The extra features of show week have been numerous. Tuesday evening Paul Revere Hall was thronged with members of the Bay State Automobile Association and their ladies at the ball given by the association. This was the first attempt of the show management and of the Bay State to hold a social affair in which the ladies participated, but it was a thorough success. Dancing began at 11 o'clock, a half hour after the close of the show, and it was not until an early hour Wednesday morning that it ceased, and the dancers went home in the limousines and taxicabs. To-day has been a very busy time at the show. For one thing, it has been dollar day, when the exhibitors expect to meet their choicest prospects, and therefore have been keenly alive to the possibilities of every visitor at the spaces. Secondarily, it was motorcycle day, and motorcyclists from all parts of New England, and not a few from New York, were here. Thirdly, the executive committee of the American Automobile Association held its annual meeting in Mechanics' Building, and everybody was on the *qui vive* to see if any action would be taken in regard to the Glidden tour or other important matters.

To-morrow (Thursday) the feature is the run from New York to Boston, in which many cars have been entered. The cars will leave New York at 8 o'clock in the morning and are expected to finish here in the early evening. Incidentally there are not a few trade dinners and other social affairs on hand to take up the time of the exhibitors after 10:30 at night.

From the Huntington Avenue End of the Main Hall the View Was Impressive—a Fitting Culmination of the Season's Great Industrial Exhibits.

The Reflection of Thousands of Brilliant Lights at Night Mellowed the Decorations with a Soft Glow.

PYRAMIDED superiority is the summation of the increments for quality, eked out of all the cars, but the height of the pyramid, and its nice proportions, gained immensely at the Boston show, due to the presence of cars of splendid promise, exhibited for the first time, braving the metropolis of the sagaciously conservative, at small risk of adverse criticism, due to the enlightened state of automobile designing on the one hand, and the profusion of superior materials to be had for the asking.

Buyers of cars have automatically contributed a large quota to the success of the ventures in that they now know what is best for use, and it is but to supply definite wants when new cars are projected into the arena of popular favor. Because builders, and buyers, alike, understand the situation perfectly so-called freaks and slants at odd angles from the designer's point of view are not indulged in, and it was regarded as distinctly elevating to go into the Boston show for no other purpose than to critically examine the newcomers, basking in the sunlight of conservative features, strong with good materials and bristling with that formidable array of armament, beaten into form sublime in the smithy of simplicity, launched in a sea of art.

Napier, American Napier Company, Boston.—Perhaps the new 40-horsepower Napier is so much in line with the generally well-known characteristics of the "parent car" that its presence at the show indicated the usual interest rather than something to be called by a new name. At all events, as the illustrations here offered will show, the reasons for the keen interest taken in the Napier exhibition are too good to require comment. As a lightweight automobile of vast indurance and great flexibility, the new model struck a responsive chord in the hearts of the buyers of Boston, and with such features as Bosch magnetos of the latest and most approved type, for the ignition system, coupled with the utility of the new Hoyt carbureter (designed by Superintendent F. C. Hoyt, of the company), the situation looks pleasant. But the Napier company proposes to go far beyond the mere production of a standard touring car, and in the making of the roadster type all the so-called innovations of automobiledom will be boiled down to absolute finality before they can fit into a description of this Napier creation. The future of the company will be to the tune of a new light delivery wagon, and it is whispered about that the new "compressed air" exploitation will make for history in transmission systems in some Napier cars.

Compressed Air Power Company.—The novelty of the Boston show was conceded to be the landaulet, as exhibited by the above-named company, in which compressed air is the transmitting medium; the prime source of power being a gasoline motor. What the company aimed at was flexibility such as can never come with the use of sliding gears and the car, as it was seen at the show, impressed the spectators as being the product of experts with definite ideas of what they want to accomplish.

The installation includes an air-cooled gasoline motor, cooled by the exhaust air, from the air-power motor, it being the case that the exuding air from the power motor is cold enough to form ice if it is expanded from pressures such as can be used, and it follows that there is a wealth of a cooling medium with which to keep the air-cooled gasoline motor at any desired temperature. The gasoline motor drives a compressor, and the compressed air derived therefrom is passed through a "re-heater" so that it enters the air-power motor at high heat and pressure furnishing power to the road wheels of the car.

The high pressure heated air is enabled to expand to a low point without "iceing" the valves, and the economy resulting is very high, indeed. The air-power motor, like a steam engine, will run in both directions, and power can be realized at all speeds. Regulation is precisely on the same basis as would be the case with a good steam engine and as a result transmission gears are not needed at all. Plainly, then, the flexibility which is present in steam practice is expected in connection with the car as fitted with the air system, which reports seem to agree with.

The exhaust air is available for all auxiliary purposes as inflating tires, blowing the horn, and, as before stated, in cooling the gasoline motor. The equipment has attracted much attention, and it is said that the Napier Company of America will fit out some cars this year with the compressed-air power plants of this make. Frank Lester, whose experience in this line dates back for some years, rushed the first car to completion for the Boston show, beginning last Thanksgiving Day at the plant of the Atlantic Works, East Boston.

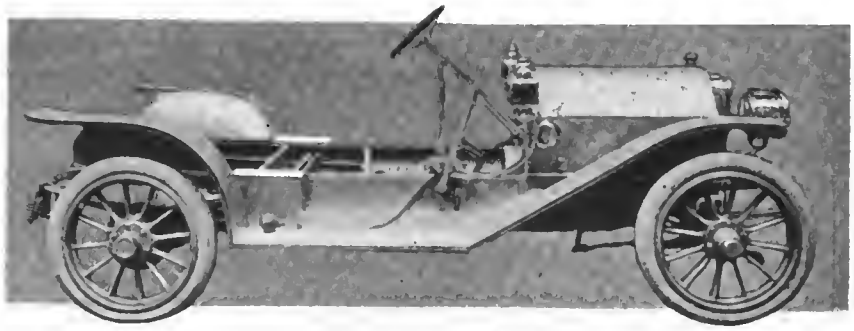
Herreshoff, Herreshoff Motor Company, Detroit.—The makers of the Herreshoff state that their car was designed primarily for the owner of a heavy car who desires in addition a machine suited for fast city and suburban work. A heavy car in congested traffic is often in the position of the proverbial bull in a china shop; it blocks the street every time it turns around. if it is true that it can be turned around without backing and filling, so to speak, several times, due, as it is well understood, to the law governing the turning radius of all automobiles, in which wheelbase and angle of the front road wheels, as they are canted for turning, render the problem easy, or not, depending upon the details of design present. A light car suffers none of these disadvantages; of comparatively short wheelbase, it is adapted for a quick turning radius, and its light weight alone

makes it easily checked or accelerated. The Herreshoff motor has four cylinders cast in pairs, of 3 3-8 inches bore and 3 3-4 inches stroke. It is designed to run at from 200 to 2400 r.p.m., and is rated at 24 horsepower. The crankcase casting is extended rearward to include the flywheel and the gear box, the essentials of the power plant thus forming a single, compact unit on a three-point suspension. The motor is fitted for double ignition, but the magneto is listed as an extra; cooling is by a vertical tube radiator with thermo-syphon circulation. Power is transmitted through a 25-disc steel-on-steel clutch to a three-speed gear of the progressive type. The gears are of projectile steel, cut to insure absolute quiet and non-stripping. The drive shaft is enclosed in the torsion tube, and has a single joint of the spherical square type. The torsion tube has diagonal braces extending from the joint to the rear spring seats.

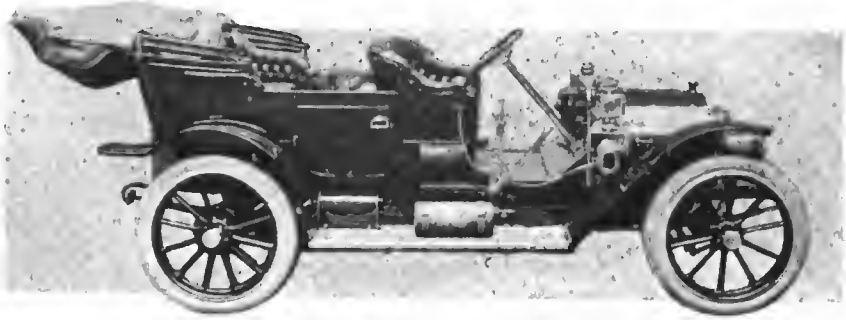
The running gear includes a live rear axle with floating shaft and a drop-forged I-section front axle, both carrying 32-inch wheels with 3 1-2-inch tires. Brakes are internal and external on the rear hubs; a single pedal controls the clutch and the service brake by a progressive motion. The chassis is fitted either with a five-passenger touring body or a neat rumble runabout. Herreshoff cars are handled by the French Carriage Company, 92 Summer street, Boston.

Pickard, Pickard Bros., Brockton, Mass.—This car made its début "at home" and the Model E runabout at $750 measured for supremacy with a long steel tape, most accurately graduated, so the story goes. In this car the front axle is of manganese bronze, of the I-section, nicely proportioned. It will be remembered this is the famous bronze which costs several times the price of steel, and the strength of the bronze is 80,000 pounds per square inch tensile strength, with an elastic limit of 36,000 pounds per square inch. The rear axle is of the live floating type fitted with ball bearings, light, strong and with good ground clearance under the differential housing. The motor is air cooled and is rated at 25 horsepower and rests on a sub-frame, taking its mixture from an automatic carbureter, exhausts into a muffler which renders the exhaust silent, but the performance is in the absence of any back-pressure; 20 gallons of gasoline will fit in the tank and it is ignited at the propituous instant through the good office of a coil of suitable quality using electricity from dry cells. With a rated speed of 50 miles per hour, in view of the commodious body and upholstery that ranks with comfort, it is easy to account for the unusual state of affairs which makes the Pickard "a prophet at home." The South End Car Company holds the agency for the Pickard and it looks like a happy combination.

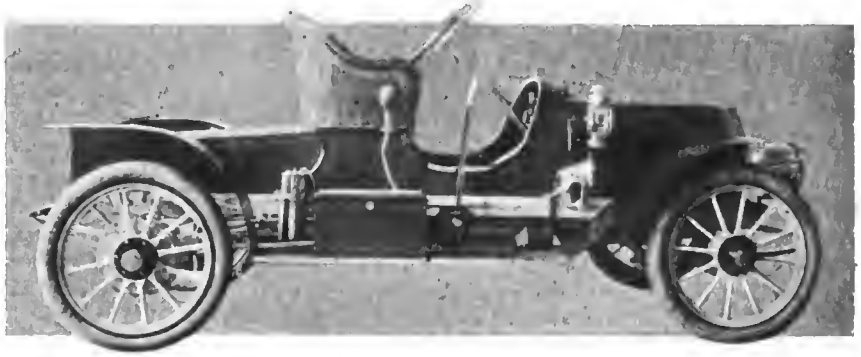
Hupmobile, Hupp Motor Car Company, of Detroit, Mich.—Entered the show for the first time, but by no means as a stranger, due to the facility with which news travels and the splendid home performance of the cars of this make. The 16-20 Hupmobile is distinctly different, made so for a purpose. Briefly, this car is low in power, but it is also low in



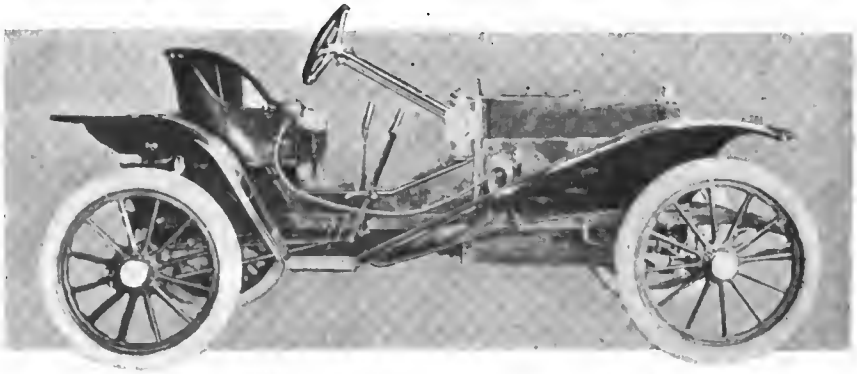
Napier 40-Horsepower Chassis—American Napier Co., Boston.



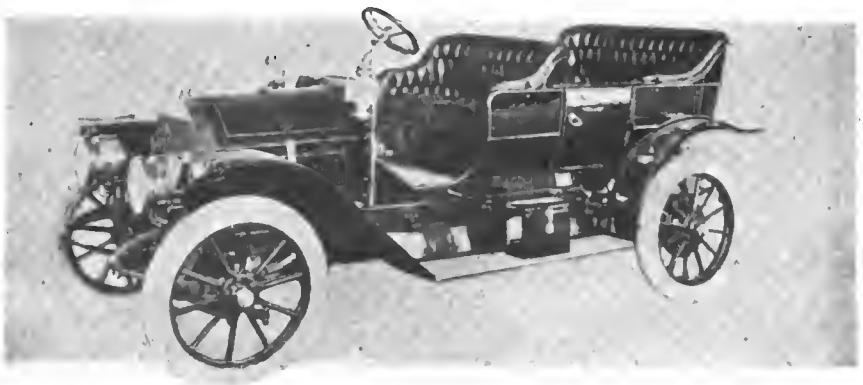
Herreshoff 24-Horsepower Car—Herreshoff Motor Co., Detroit.



Pickard 25-Horsepower Air-Cooled—Pickard Bros., Brockton, Mass.



Hupmobile 16-20-Horsepower—Hupp Motor Car Co., Detroit.



Velie "30-Limited"—Velie Motor Vehicle Motor Co., St. Louis.

Connecticut's Newest Car—The McCue, from Hartford.

Where the Grout Cars Were Displayed by Agent Farrow.

weight. It is, therefore, a big automobile since the reduction in weight is not at the expense of cramped quarters within the ample folds of the splendid body that graces the chassis. Looking at the "Mercedes" front of this car, glistening in its simple elegance of design, excites interest with a dull sense of high price, which feeling is dispelled when the genial salesman pronounces the sentence "The price is $750." The car weighs 1,100 pounds, is of absolutely conventional design, with channel section steel side-members, half-elliptic springs on front, three-quarter platform springs to the rear, shaft drive, with two sets of splendid brakes, and the water-cooled motor is fitted with a Breeze carboreter, while the cooling is done with a tube radiator of very neat and substantial design. It is needless to point out that the propeller shaft is provided with protected universal joints and that the car as a whole is a sure cure for skeptics. Henry F. Farrow is the agent, at 117 Massachusetts avenue.

Velie, Velie Motor Vehicle Company, Moline, Ill., entered Boston with the "30-Limited" and settled down to be admired. The touring car of the line sweeps back from the cooler, which starts on the center line of the front axle, just as modern automobile designing demands, and the flare of the mud-uards has the advantage of being good; they look like business, too. In the first place, the shape is such as to allow one to work on the tires and the chassis is perfectly protected. It is a chassis well worth protecting, and the long wheelbase allows of a body with room, and more room. The three-quarter elliptic springs in the rear assure that level platform about which we hear so much, and the steering gear is not only in fine form, but the materials, as well as the way of their use, augurs for stability. The hood is of nice shape held in place with straps of heavy section, and the power plant, nested under the bonnet, is a consistent and "sweet running performer." The price of the car is $1,750, ready to run, and sharps, who keep tabs on such things, say "the Velie has a clean pair of heels." The rest of the company's line included a roadster, low, long and rakish, light, lythe and takash. The Boston end is handled by Kilbourne Corlew Motor Company, located at 26-28 Bowker street.

Manager Campbell Consults the Telephone Directory

Chas. Waugh & Company, Cambridge, Mass.—The American one-ton delivery wagon and five-ton truck and the Commercial 1000-pound electric wagon comprise the line of commercial cars exhibited at this stand. The truck is driven by a four-cylinder, 40-horsepower motor with separately cast cylinders, placed under the footboard. Transmission is through an inverted cone cluteh, two-speed planetary gear and side chains. The construction seems substantial, as is fitting, considering the load to be carried; the rear axle is a solid steel bar, 2½ inches square, and the pressed steel side bars of the frame are 6 inches deep. The delivery wagon carries its motor under a regulation hood; the cylinders are cast in pairs with opposite valves, and the change-gear is of the three-speed selective type. The Waugh Company also makes cape and canopy tops, and does a considerable business in making parts to order from original designs and in reconstructing and remodeling.

AMERICAN NAPIER COMPANY REORGANIZED.

Boston, March 8.—With the consent of all the stockholders, the Napier Motor Company has been reorganized as, or rather superseded by, the American Napier Company, a Maine corporation with $1,000,000 capital, most of which has been written up. The new company is headed by Otto B. Cole, as president and general manager, with M. C. Barnard, vice president, and Fred L. Hall, treasurer. These three, with Wm. H. McMasters, Joseph Ellwell and Leon Pettit, Jr., constitute the new board of directors, the old board having resigned.

The plant of the older concern, at Jamaica Plain, Mass., has been acquired, put in working order and some additions started, among which is a three-story machine shop. A number of men have been put to work and the factory is busy getting out machines for spring and summer delivery.

The new company will have the same arrangements with the English Napier Company as did its predecessor in the way of contracts and patent rights. Consequently, the output will be patterned along the line of the latter, although by no means as extensive. This will include the new 40-horsepower four-cylinder model as exhibited at the Boston show, a medium-priced light weight roadster, a taxicab model and possibly a new style of light delivery wagon. As light weight is the Napier slogan, the details of the roadster are awaited with great interest, the larger car at the show having shown up well.

Among the features of the cars will be the rear axle construction, double ignition with Bosch magneto as the principle source of current, and a special carbureter invented by Superintendent F. C. Hoyt. A few cars will also be built using the compressed air type of transmission; in fact, the Compressed Air Power Company has been given an order for the transmissions.

The details of the New York City branch are being arranged, as are also other branches. For the convenience of Boston owners, a shop repair department has been established.

What Leading New England Accessory Makers Had to Offer

Atwood-Castle Company, Amesbury, Mass.—Gas and oil lamps of all kinds and sizes may be seen at this exhibit. One of the new gas headlights is made especially to harmonize with the straight-line bodies now in vogue. Its lines are simplified as much as possible, and the ventilators in the hood are made diamond-shaped, giving an unusual and distinctive touch to the lamp. Not to show any partiality, however, the company shows another lamp in which not a single straight line is to be found, while curves riot in luxurious abundance. All lamps can be furnished in the popular black finish at a slight extra charge.

Allen Fire Department Supply Company, Providence, R. I.—The Allen two-port carbureter seems to go back to first principles in some respects, as it embodies a positive control of the vapor and auxiliary air operated directly by the throttle. The device gets its name from its two parallel passages, one for pure air, the other containing the spray nozzle. The throttle is a flat plate with suitably shaped openings which slides over the upper ends of the two passages and opens them in proportion to the speed. In this way a high degree of simplicity is attained; there are no springs to be changed in tension by heat or long use, no diaphragms, no dash pots or sensitive valves. The device seems substantially built, and with proper proportioning of the openings, which no doubt has been attended to, it should give good satisfaction.

Bi-Motor Equipment Company, Boston.—The difficulty often found in arranging a tail-light to light up the rear number tag is obviated by an electric device shown at this stand, which may be attached to any part of the car. Those who own machines with extra long tonneaus will find the comfort of their passengers increased by a folding foot-rest, also made by the Bi-Motor Company. In addition to a full line of accessories this company handles the Pfanstiehl coils, which are new to the Eastern market. These are of the same design as the coils used in x-ray work, and give what the makers call a "caterpillar flame." Any Pfanstiehl coil unit, with a ten-volt current and an x-ray tube, may be used to produce x-ray. The coils are tested on a 16-volt current.

Boston Auto Gauge Company, Boston.—The "Triumph" tank gauge is claimed to be unique in that it necessitates no hole through the wall of the tank, and breakage of the glass will not cause a leak. The interior part of the gauge consists of a tube with a spiral slot, with a float inside which engages with the slot so as to turn with every rise of the level in the liquid. The float carries a small magnet, and the gauge needle, being itself magnetic, follows the movements of the float on a graduated scale. Another form of the gauge may be fitted to the dashboard.

Burn-Boston Battery Company, Boston.—This company shows a new type of wet primary cell, intended to replace dry batteries. These batteries are square in shape, and it is claimed that they lose no current when not in use and will not dry up or freeze. Its freedom from deterioration makes it especially adapted for use as an auxiliary with magnetos, as ordinary batteries when used in this way waste more current than they give. The amperage is about the same as that of an ordinary dry cell. The company's headquarters are at 9 Duane street, Boston.

L. C. Chase & Company, Boston.—All kinds of fabrics for automobile use are shown at this exhibit, but the specialties are mohair mackintosh, rubberized cloth and "Chase leather," for covering folding tops and slip covers. The rubberized fabrics are made in both single and double texture, in a variety of grains and finishes. In double texture these fabrics make an unusually reliable top material, as they contain two thicknesses of cloth with a rubber proofing between, and a second rubber coating between. The company's offices are located at 89 Franklin street, Boston. A folder is being issued containing samples of the different fabrics.

Coates Clipper Mfg. Co., Worcester, Mass.—Autoists who take pride in the neat appearance of their brass work will be interested in the Coates auto buffing outfit, which with a mini-

Most of the Accessory Exhibits Were Admirably Situated in the Spacious and Well-lighted Gallery.

Where the Atwood-Castle Lamps Were Quartered.

mum of labor will enable him to use his lamps as mirrors. The outfit is driven from the right rear wheel of the car, previously jacked up, and sufficient length of shafting is furnished to reach the headlights without difficulty. The same outfit with a drill or an emery wheel in place of the buffer may be used for drilling or grinding. Coates flexible shafting is made in sizes to transmit from 1-10 to 150 horsepower, and may be used in connection with anything from a speedometer to a heavy machine tool. The exhibit included an emery wheel turning 21,000 r.p.m., and a number of drills and other tools driven by electric motors on the other side of the stand, the connecting flexible shafts giving the place the appearance of the cageful of boa constrictors.

Coes Wrench Company, Worcester, Mass.—One of the features of this exhibit is a massive Coes "steel handle" wrench at least four and a half feet long, which lies on the desk in front of the stand and rarely fails to attract the attention of passers-by. It certainly was not intended for automobile work, as it would require a tool box as big as the car itself to carry it. Of much more practical interest from the autoist's point of view is the new four-inch wrench, which weighs but seven ounces and opens 13-16 inch. It is just the size for the many small nuts

An Aisle in the West End of the Main Building.

on the carbureter and ignition system, and is especially adapted for motorcyclists' use.

J. W. Colgan Company, Boston.—Not only do demonstrators and agents usually desire to have the name of their car prominently displayed on the radiator or running board, but there is a rapidly growing custom among private owners of giving their cars an individuality by the use of monograms or crests. The Colgan Company, Sudbury Bldg., Boston., makes a specialty of this sort of work, and their monograms are original and distinctive in style. It also makes medallions to be attached to robes and other loose impedimenta. The exhibit includes specimens of the different styles, and an illustrated booklet is also issued. In addition to these, any design can be made to order.

Couch & Seeley Company, Boston.—A scale no less than 28 inches long, with individual 5-16-inch figures for each mile, is the distinguishing feature of the Casgrain speedometer made by this company. The device itself is of distinctive form, consisting of a horizontal cylinder intersected near the right-hand end by the vertical drive shaft. The right-hand portion contains the trip and season odometers, and the larger left-hand portion the speedometer proper. The figures appear through an aperture in the case, and no more than three can be in sight at one time. The principle is novel; a horizontal shaft carrying paddle blades rotates in a liquid in the center of a cylinder carrying the figures of the scale arranged spirally. The friction of the rapidly moving liquid then carries the scale cylinder around wtih it against the tension of a spring. As there is no mechanical connection between the driving mechanism and the scale all inaccuracy from wear is eliminated, and careful precautions are taken to insure against the escape of any of the liquid. The instrument is compact and of neat appearance.

Dover Stamping and Mfg. Co., Boston.—Sheet metal specialties of all descriptions form the basis of this exhibit. There are oil cans and oil guns of every shape and size, long spouts, short spouts and no spouts at all. The stand is walled in with galvanized iron drip pans, to be placed under the cars in garages. The pans receive all drippings of oil and gasoline, and not only keep the floors clean but considerably reduce the danger from fire.

Essex Brass Foundry Company, Cambridge, Mass.—As its name indicates, this company makes brass castings for all kinds of automobile and motor-boat use. One of its specialties is a patented folding-top support, which provides a resilient support for the bows of the top when folded down and prevents their breakage. It is made of manganese bronze and highly finished. Steering wheels and propellers for boats and door handles, foot rests, robe rails and other fittings for autos are also shown.

Federal Mfg. Co., Lowell, Mass.—The makers of the Rex storage batteries have put on the market a spark coil known as the Bliss, a feature of which is a new torsional vibrator. The vibrator points are made of a special iridio-platinum alloy to obviate pitting. The cases of the unit coils are of hard rubber and provided with anti-induction shields, which prevent the activity of one coil from exciting a current in its neighbor—often a cause of irregular firing. The coils are said to operate one 1-10 ampere.

Ernest Flentje, Cambridge, Mass.—Flentje shock absorbers are built on the same principle as the glycerine recoil checks used on 12-inch cannon. They consist of a cylinder and piston, one to be fastened to the axle and the other to the frame of the car. The cylinder is filled with glycerine, and the piston has bored in it six holes, two small and four large. All are open when the piston goes down, so that the downward motion is unchecked, unless it becomes too violent; but on the return stroke the large holes are closed by check valves, so that the glycerine must all pass through the two small ones. This makes a very effective damper on the rebound of the springs. The devices are made of phosphor bronze and steel, the cylinders being fin-

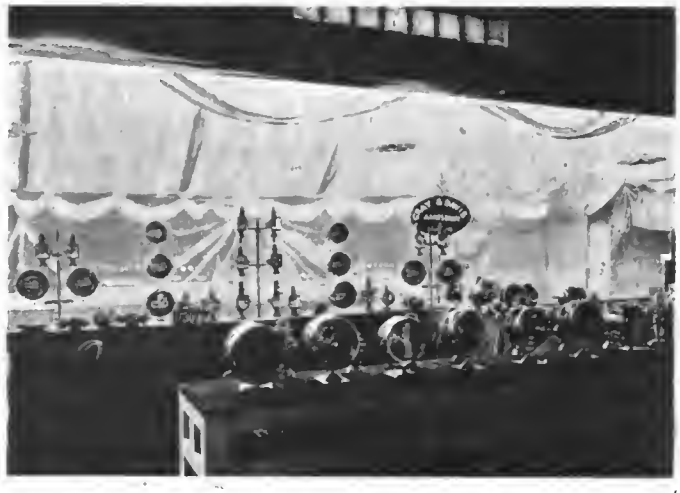
ished in nickel, while the hangers may be painted to match the rest of the car.

Gordon Auto Supply Co., Boston.—This company shows an extensive line of automobile supplies, among which may be noted the Whittaker tire chain. The cross chains of this device are made of hard steel wire, hand-welded, and copper-plated. The side chains are fitted with snap hooks, which simplify putting on and removal. The Gordon company is also New England distributor for the Geiszler non-sulphating storage battery.

Gray & Davis, Amesbury, Mass.—The Wridgway "No-glare" shade, shown on Gray & Davis headlights, is an innovation that will be welcomed by all who have ever been caught in front of a dazzling acetylene beam, as this shade prevents any diffusion of light above the level of the lamp itself. It consists of a series of thin horizontal plates across the face of the lamp behind the front glass. These are dull black on top, so that all upward rays are absorbed, and silver-plated beneath, thus intensifying the light cast on the road. The shade can easily be attached to any lamp. It is interesting to note that a law recently passed in New York makes the use of some sort of shade obligatory on headlights.

Heinze Electric Company, Lowell, Mass.—An exhibit at the Heinze stand which never failed to draw a crowd was a monster spark coil, two feet long, with distributor and plugs of proportionate size. The plugs, mounted high in the air, gave forth sparks of a size more suitable for a wireless telegraph outfit than an automobile; and the distributor, from which the cover had been removed, kept up a fine display of fireworks on its own account. On the other side of the stand was a dummy wooden model of a four-cylinder motor, the shaft of which was geared to one of the new Heinze magnetos. The whole apparatus was turned by a crank, and demonstrated very effectively the ease with which a car can be started with a modern design of magneto.

Hoffecker Company, Boston.—"The Steady Hand" is the watchword of this company, whose speedometers are now beginning their third year on the market. The mechanism works on the centrifugal principle, and the connection between the governor and the indicating hand is made by a special system of levers so arranged that no vibrations can be transmitted. The dial shows a circular miles per hour scale in heavy black, with a black indicating hand, and around the outside of this a trip odometer scale reading to 100 miles, in red with a red indicating hand. The season odometer dial is of the usual type, with figures showing through an aperture in the lower part of the dial. This speedometer is also furnished mounted by the side of a Chelsea clock, with a small electric light and reflector, and in this form is known as the "Hoffecker twin."



Here It Was that Gray & Davis Lamps Shone Brightly.

Holtzer-Cabot Company, Brookline, Mass.—These latecomers are showing the newest thing in electric horns. This horn is operated by a direct current and may be wound to work on pressures up to 123 volts for 5 hours without heating. By a new form of contact, sparking even at very high voltages has been practically eliminated. The horn is compact, water-tight and can be relied upon absolutely, which accounts for the fact that the United States Navy has adopted it for emergency signaling. This statement alone speaks volumes for the actual merit of the device.

Hopewell Brothers, Cambridge, Mass.—A spare tire carried on the running board or on the rear of a car at best does not add to its appearance, and to make this necessary article as little offensive to the eye as possible it is well to enclose it in a neat-appearing case. Such is the philosophy of the Hopewell Brothers. Their case is held on by two endless spiral-wound springs, and has no straps, buckles, buttons, or other exterior fastenings.

Hoyt Electrical Instrument Works, Penacook, N. H.—The Hoyt voltammeter consists of two separate instruments, the voltmeter and the ammeter, which are intended to be mounted

A Glance Down the Long Aisle in the Second Floor of Big Triangular Eastern Section of Mechanics' Building.

together on the dashboard. The windings of both are so calculated that they consume only a very small amount of current, and so they may be kept in circuit constantly without detriment to the batteries. Used in this way they give the driver of a gasoline car the same constant knowledge of his ignition system that the steam engineer has of his steam supply. The instruments operate on the D'Arsonval principle, which is the standard for scientific work. The moving parts are mounted in jeweled bearings, and although very sensitive to changes in the volume or pressure of the current are at the same time dead-beat in action. The cases are made in a variety of finishes to match the other metal work of the car to which they are to be applied. The voltammeter not only indicates the condition of the batteries at all times, but is also an efficient trouble-finder for any part of the ignition system, as the readings of the instrument often show where any fault lies. A booklet issued by the makers from their office at 161 Summer street, Boston, clearly explains the use of the instruments in this way, and also gives diagrams of the connections necessary to install them in the ignition system.

Chas. W. Kidder, Stoughton, Mass.—A new design of shock absorber which shows considerable merit is the Monarch. The principle is that of the cam with spring-pressed follower. The body of the device is rigidly bolted to the frame of the car, and the cam is connected to the axle by a crank and link of suitable length. The cam is shaped to give a gradually increasing resistance to excessive motion in either direction, and a positive stop at the limit of action which will be dangerous to the springs of the car. The mechanism is of course carefully enclosed to prevent the entrance of dust and grit.

Kilgore Mfg. Co., Boston, Mass.—The Kilgore shock absorber is designed to make use of the elasticity of air to eliminate the jolts and jars to which an automobile is subjected. A cylinder, full of air, and a tight-fitting piston comprise the essential parts of the device. A narrow passage in the cylinder wall short-circuits the air, as it were, and allows the piston to move with comparative freedom within a short distance on either side of the middle of its stroke; but a further movement of the piston covers the opening of this passage, and the remaining air is entrapped and compressed. A too violent movement of the springs is thus immediately checked.

W. H. Leland & Company, Worcester, Mass.—Well known to the trade as a manufacturer of finished crankshafts of exceptional quality, this company has also put on the market the Worcester spark coil. This coil is mounted on a swinging bracket especially convenient for use on roadsters and other cars with hooded dashes. If the coil is rigidly affixed to the dash, the hood makes adjustment of the vibrators extremely difficult. The "Worcester," however, may be swung out into full view whenever desired for inspection or adjustment. The high-tension terminals are arranged very neatly, ending in hard rubber bolts which slip into the bottom of the case and are held in place by nuts of the same material. The coil is fitted with a neat design of kick switch.

Looking Down from the Gallery in the East Wing, Where the Skylights Made the Lighting Advantageous and Effective.

Parker Mfg. Co., Roxbury, Mass.—The Standard speedometer marketed by this concern is another example of the centrifugal type. Its distinguishing feature, however, is the method of actuating the indicating hand by direct gearing from the governor weights, without cams or other intermediate mechanism. The scale is evenly spaced and easily read. A new form of trip odometer is used, in which the figures are on a ring-shaped plate beneath the face of the dial and appear through a suitable aperture above the speed-indicating scale. An improved form of swivel joint is used on the driving mechanism on the front axle and is claimed to obviate breakage of the shafts.

Pittsfield Spark Coil Company, Dalton, Mass.—The Pittsfield line of coils and plugs is already familiar to the trade, and the new "arc flame" magneto is rapidly acquiring the same prestige. Improvements in the standard accessories are in details only, such as a new side catch on the coil to hold the top in place, a coil with hinged bracket supports, and a kick switch for magneto and battery or double batteries with a safety plug which cannot be replaced by a nail or a cotter pin. A new plug is listed for use with the "arc flame" magneto.

Post & Lester Company, Boston.—This well-known supply house shows a standard line of accessories, ranging from

How the Boston Show Was Lubricated

watch fobs to spark plugs. One interesting exhibit is the new Rushmore Multiplex searchlight, for which this company is New England distributor. The front door glass, instead of heing flat, is made in four slightly convex lenses, set vertically, which spread the light out in a broad, flat beam. They have the additional advantage of doing away with the flickering which is often so objectionable. Hanging across the front of the stand is a horn shaped like some monstrous variety of snake, the tube forming the body and the bell the head, made in exact imitation of a snake's head even to the forked tongue. It looks very formidable, and should be useful in securing a quick and unobstructed right-of-way.

Randall-Faichney Company, Boston.—This company is well known as a manufacturer of high-grade surgical instruments, and experience in this line may account for some of the fine workmanship to be seen in their automobile accessories. The feature of the Back Bay and Broadway oil guns is that they may be operated with one hand. Both are made of seamless brass tubing, and have metal plungers ground to fit—no packing. The line also includes a grease gun and a gasoline primer. Another useful specialty is the Webster gasoline tank gauge; this is actuated by a spherical metal float connected by a long arm and positive gearing to the indicator on the top of the tank. In connection with this is furnished a tank cutter, to be used in a bit-stock to cut a hole in the tank to which it is desired to affix the gauge. The float and other fittings may be introduced through this hole, without any other means of access to the interior of the tank, and without danger of dropping them inside. It is claimed that the hole can be cut and the gauge inserted in ten minutes. The very latest addition to the line is the Tzar horn. This is easily attached, requires no cleaning, never clogs up, and will outlast the car, in fact. It is operated by the exhaust, which insures more noise and greater convenience in operation. As it is readily attached to the end of the muffler, no especial preparations for its use are necessary, and a real mechanic could put it on in less than an hour. In addition to all these virtues, the price is low so as to place it within the means of all.

Shawmut Tire Company, Boston, Mass.—This company, recently established at 97 Bedford street, with factory at East Watertown, Mass., has put on the market a tire of standard design for which, however, it claims a number of advantages. The rubber is applied by a special process and is vulcanized at a comparatively low temperature, so as to avoid burning or weakening the fabric. This is claimed to eliminate blowouts to a large degree. Shawmut tubes are made of such tough rubber that no flap is needed to protect them from the lugs. The Shawmut Company also makes a full line of cement, acid, patches, tools, and other tire accessories.

Springfield Portable House Company, Springfield, Mass.—A 12 x 18 garage set up on this space leaves passers-by in no doubt as to the business of this company. The garage is formed of sections which may easily be taken down or put together. The hip roof is shingled and the walls weatherboarded. The swinging doors in front open to nearly the full width of the building, and two windows are provided on each side. It is attractively finished in white with dark green trimmings. The company not only makes small buildings, such as garages and work-shops, but even complete eight and nine-room cottages. Autoists who live in suburban districts, if they have even a very little room in the yard, will find the portable garages, as made by this company, not only good for the purpose, but they are in ornamental designs conforming to the needs. The cost of a "portable" will soon be made up in saving of garage charges.

Winestock Mfg. Co., Perkinsville, Vt.—Winestock spark plugs show a new application of the detachable principle. The shell is intended to be permanent in the cylinder; the plug proper is secured in the shell by a bayonet lock, released by a quarter turn. One model has insulated lugs projecting at right angles to give a good finger grip for turning, and the other has a folding handle for the same purpose. The spark gap is adjustable to micrometer fineness. The same company also makes "Cedaroleum," a hand-cleaning fluid which contains no alkali or grit. It is also used on oil or water stones for sharpening tools, and for cleaning windows, so that it is capable of serving for a wide range of uses with the automobile.

After Passing the Main Entrance Visitors Take Their Choice of the Two Diverging Aisles that Lead to the Exhibits.

TWO NOVELTIES SEEN AT THE BOSTON SHOW.

A Canadian Demountable Rim.—The Standard Combination Motor Rim Company hails from Toronto, Canada, and its exhibit at the show attracted more than a little attention, presenting novelty entwined with utility, in the form of a demountable rim. This rim is parted at one point, and means are provided for expanding the same to get it off of the felly. When the rim is removed it is possible to replace and inflate the tire, after which the whole will slip into place and the locking device enables the whole to be put into place quickly and securely. One of the side flanges comes off in the process and the tire can therefore be taken off and replaced easily. When the rim is mounted, side fasteners, at three points, prevent it from drifting off, and every provision is taken to enable the autoist to do the work with almost no effort, yet with all the security means are adequate for the purpose. The rim is drawn tight at the parting line by a double turnbuckle with a right and left thread.

Seaton Spring Wheel.—Hurbert H. Ward & Associates, with headquarters at 227-235 Williamson Building, Cleveland, O., exhibited the "seaton" spring wheel at the Boston show and while their presentation of the wheel was on a basis to attract attention the wheel would accomplish that feat unaided. Briefly described, the wheel is really a wheel within a wheel with a double set of concentric fellies, in which the inner felly is attached to the hub by spokes in the usual manner, and the outer felly is fastened to the inner one through a series of coil springs in which the axis is at right angles to the radial plane of the wheel. The solid rubber tire is on the outer felly and the resiliency of the tire coupled with the effect of the series of springs is claimed to more than compensate for the absence of air in the tire. The spokes of the wheel proper are of wood and in some measure the ability of this wood adds to the good effect. The wheel is nicely designed, amply strong for the purpose, and unlike most built-up wheels, it is not unduly heavy. As a rule the "flywheel" effect of wheels, in which a spring system is used, is far more than can be countenanced, unless it is that the car on which they are used is to go very slow.

RECENT DOINGS OF THE BOSTON TRADE.

Essex Brass Foundry Company, Cambridge, Mass.—These brass founders, formerly of Amesbury, Mass., have removed to Cambridge, where, at 141-145 Main street, greatly increased facilities will be afforded. As the name would indicate, the specialty is brass and aluminum castings.

Pickard.—The South End Motor Car Company, of 24-28 East Concord street, agents for the Atlas, Brush and Metz, formerly the Waltham, have taken on the Pickard, a new runabout emanating from Brockton and selling at $750.

Mora.—The G. H. Proctor Supply Company, of 25 Irvington street, has been appointed agent for the Mora car, manufactured in Newark, N. Y., and will start in immediately to push the sale of them.

Herreshoff.—The Boston agent for the Clement & Bailey electric, the French Carriage Company, will in the future sell the new Herreshoff car also. This concern is located at 92 Summer street.

American Simplex.—A recent change in address for the American Simplex Company, handling the two-cycle car in the Hub, places this company at 10 Columbus avenue.

Gramm-Logan.—S. M. Harmon, the Eastern representative of the Gramm-Logan Motor Car Company, manufacturers of motor trucks, has located at 22 Motor Mart.

Post & Lester Co.—The retail branch has moved from 815 Boylston street to 16 Park square. In addition, a wholesale store has been opened at 288-290 Devonshire street.

De Luxe.—Donald MacVichie, formerly of Chicago, has taken on the De Luxe agency and opened a store at 171 Huntington avenue, in the New Century Building.

Midland and Marion.—The New England Motor Sales Company, managed by B. F. Blaney, has taken this territory for the Midland and Marion cars.

Middleby.—The Boston agency for the Middleby, an air-cooled car, has been secured by the Malden Center Garage Company.

Kilgore.—The Kilgore Mfg. Co., manufacturer of shock absorbers, has opened a new salesroom at 585 Boylston street.

Holsman.—The agency for this high-wheeler has been taken by the General Auto Company, 10 Columbus avenue, Boston.

Hupmobile.—Henry F. Farrow, 117 Masachusetts avenue, agent for the Grout, has added the Hupmobile to his list.

Velie.—The Kilbourne-Corlew Company, 28 Bowker street, will represent this Western car in the Hub from now on.

Browniecar.—The New England Auto Company now has the agency for the new juvenile, the Browniecar.

Lambert.—Charles A. Eaton, handling the Lambert friction drive car, is now at 64 Pembroke street.

Matheson.—Roy Faye, the Matheson agent, has moved from Cambridge to 823 Boylston street, Boston.

MILWAUKEE SHOW OPENS SUCCESSFULLY.

MILWAUKEE, WIS., March 9.—Wisconsin's first annual show opened at 8 o'clock to-night, and it is already evident that the people of the State have long been waiting for this opportunity to see almost every known make of motor car assembled under one roof, beautifully decorated, and conducted by an organization like the Milwaukee Automobile Club.

Thirty-eight agencies purchased all the show space available, and cars are displayed even on the balcony floor of the Hippodrome. Four motor cycles are on exhibition in one corner, and the remainder of the floor is devoted to accessories, supplemented by displays in rooms off the main floor.

The show is proving to be one of the greatest society events of the season. In anticipation of this, the club arranged for luncheon service at all hours during the show periods, with music by orchestras and bands. Thursday will be "State Day." All of the local clubs affiliated with the Wisconsin State A. A. will be officially represented. Several tours have been arranged by clubs within striking distance of Milwaukee.

The success of the show was assured long before to-day. The club never feared that it would not draw big crowds, for hundreds of people from the interior are coming. A feature of the arrangements was an illuminated parade of over 100 demonstrating machines and private cars owned by club members, on Saturday night, March 6. This assisted greatly in waking up the people of Milwaukee to the fact that it has a real show "in its midst."

SYRACUSE SHOW ENGAGES DAI LEWIS.

SYRACUSE, N. Y., March 8.—A town that has once been bitten by the show microbe practically never recovers. This is the true explanation of the continuous increase in the number of automobile exhibitions. Last year this city was given its first show by the H. H. Franklin Mfg. Co. The affair was held in the Alhambra, the chief convention hall of the city, which was crowded during the days of the show. Following up the success of its initial show of last year, Syracuse is preparing for its second automobile exhibition, to be held in the New York State Armory March 24-27. This has been followed up by the recent formation of the Syracuse Automobile Dealers' Association, with a score or more of members, representing the automobile agencies in Syracuse and Central New York of many of the well-known motor cars. Dai H. Lewis, manager of Buffalo's successful exhibitions, has been engaged to conduct the show.

SCORE OF CARS ON RUN TO BOSTON.

NEW YORK, March 11.—In a mid-winter endurance contest, on a running schedule of twenty miles an hour, twenty-one automobiles early this morning left Columbus Circle on their way to the Hub, in competition for the Chester I. Campbell trophy, expecting to finish shortly after 6 o'clock this evening at Mechanics' Hall, where Boston's annual show is in progress. As "The Automobile" goes to press the cars are well on their way, traveling over muddy but fairly good roads.

Under the direction of Mills and Moore, this contest was gotten up almost upon the spur of the moment, but it shows that makers, dealers and owners alike, appreciate a contest at this time of the year when such an event is a diversion from the regular round of exhibitions. At 6:30 this morning the first machine, a Mora, driven by W. W. Burke, was sent away on the run of about 243 miles, making it due at the finish at 6:39, and

Campbell Cup Offered in New York to Boston Run.

the others followed at one minute intervals. The rules called for an average speed of the legal limit in this State and Massachusetts, with the same through Connecticut, several checking stations being chosen on the route, where the cars were due to arrive on their schedule or be penalized one minute for each minute late.

New Haven was selected as the first station, the first car being due at the New Haven House at 10:30; the second at the Hotel Heublein, in Hartford, at 12:36; the third at the Worcester Automobile Clubhouse, in Worcester, at 4:33, and then to the finish. From Worcester R. H. Johnston, of the White Company, has arranged to pilot the cars into Boston, the remainder of the journey being comparatively easy to follow. The roads have been covered with mud and slush for several days and a hard test was expected when the contestants left this city.

The trophy was first competed for two years ago and was won by L. H. Perlman, who has returned it to Mr. Campbell in order that it may be the prize again this year and perhaps on following occasions. The referee, Leon M. Bradley, of the A. M. C. M. A., has stated that the trophy will be awarded to one contestant, and if there is a tie to-day he has reserved the right to send the cars either back over the same route or on some other one until a definite winner is evolved. The following is the list of entrants, in the order of their start:

No.	Car.	Entrant.
1	Mora	W. W. Burke
2	Renault	Paul Lacroix
3	Haynes	W. E. Shuttleworth
4	Acme	A. B. Cordner
5	Matheson	A. D. Hall
6	Franklin	C. S. Carris
7	Kissel Kar	F. S. Dicklnson
8	Stearns	Guy Vaughn
9	National	W. C. Poertner
10	Knox	Albert Dennison
11	Zust	V. P. Pisani
12	Premier	R. R. McNamara
13	Atlas	Chas. H. Beecher
14	Stearns	M. W. Batts
15	Matheson	C. F. Rothfuss
16	Cadillac	L. R. Burne
17	Cleveland	J. I. Miller
18	Cadillac	H. A. Street
19	Lozier	C. E. Force
20	Maxwell	C. W. Kelsey
21	Coates-Goshen	A. MacRae

DAYTONA RACES WILL BE HELD.

After encountering many obstacles, which for a time made it look as if there would be no races this year upon the Florida beach, affairs have been finally arranged so that the contests at Daytona will be run off as scheduled, from March 23 to 26, and additional entries have been made. Of these there are a number of large powerful cars which have participated in many events in this country and should enliven matters in the sunny South, among them being the Fiat Cyclone with Ralph DePalma at the wheel, Lewis Strang with a special Buick, and H. J. Kilpatrick with the big reconstructed Hotchkiss.

The Fiat will defend its title to the Minneapolis trophy, won by the late Cedrino, and will be entered in every event eligible. Burman is already at Daytona with Buick cars and Strang is due to join him very shortly. It is highly probable that the two Knox cars will be contenders. Kilpatrick has rebuilt the Hotchkiss, the one which was formerly owned by E. R. Thomas, and changed its color from the yellow that became so well known to a bright red. The aeroplane race is also looking up well, a number of entries have been received, and the machines are on their way to the scene of action.

The Contest Board of the American Automobile Association yesterday granted a sanction for the races, thus closing an incident that for a time appeared to be one which might cause considerable trouble. Although there will be foreign cars competing, the event is considered to be a national one, and therefore the A. A. A. was asked for the sanction. W. J. Morgan, who has this year's races in charge, is actively engaged in the work.

NEW APPLICANT FOR BRIARCLIFF.

NEW YORK, March 9.—Automobile racing circles about this city were very much surprised, and a new puzzle added to those encompassing Briarcliff race affairs, to-day when an application was made to the Board of Supervisors of Suffolk County, Long Island, for permission to hold on certain roads a race similar to the one for the Briarcliff trophy, and in some cases said to be that event itself. The application was made by L. C. Austin, and a 60-mile course suggested, with Riverhead, Quogue, Patchogue, Huntingdon and other points, upon it.

Neither Henry H. Law, son of the donor of the trophy, Walter W. Law, and a member of the contest committee of the A. C. A., nor Percy Owen, chairman of the Briarcliff race committee, knew anything about the affair, and inasmuch as it is now up to Mr. Law to determine upon the course, rules and other matters in connection with that contest, it is not thought that he Suffolk County promoters would be able to secure the Briarcliff trophy. That, of course, would not prevent them from holding a race and donating a new prize.

WHAT SOME NEW ENGLAND MAKERS ARE DOING

By W. McKean White

SPRINGFIELD, Mass., March 8.—Present prosperity and preparation for one of the greatest, if not the greatest automobile selling season ever known in this country, is the line along which automobile manufacturers in the vicinity and in Hartford are working, making great numbers of cars for delivery when the real Spring opens and the demand becomes greater than the supply, machining great amounts of materials, and not in the least showing any fear of more financial trouble, the tariff question or of anything, except a shortage of new automobiles when dealers want them most for delivery to pressing customers.

Both the Knox Automobile Company, in this city, and the Stevens-Duryea Company, at Chicopee Falls, are working to the limit in order to fill orders which are coming in now, in a procession that has been surprising, while the Fisk Rubber Company, also at Chicopee Falls, has almost as much work as it can do in making enough tires. At Hartford, a center of the automobile industry, the story is the same, the Pope Manufacturing Company, now reorganized and out of the receivers' hands for nearly three months, not only working its big factory as fast as possible, but at night as well as day. The Electric Vehicle Company, making the Columbia cars, will be out of its difficulties within a couple of months and already many of the plans for the reorganization are well under way. The McCue Company is just waiting for the completion of its new factory and the Hartford Rubber Works is finding overtime work necessary.

Probably one feature of a trip through these factories is the enormous amount of raw material, castings, forgings and other parts, that are being machined preparatory to being used in construction, the rows of cars that have been made during the winter for Spring delivery in some places, and the general hum of industrious application to the coming problem, that of constructing enough high grade automobiles to satisfy the consumer, and there are no second-hand or slightly used cars being returned to the factories, either, for repairs or the scrap piles.

Many Cars in Stevens-Duryea Factory.

Four hundred automobiles represents a great amount of money, time and labor, but that is the number which the Stevens-Duryea Company has in its big factory at Chicopee Falls, being machined, assembled, painted, tested, or finished awaiting delivery. Between 1,200 and 1,300 four and six-cylinder touring cars and roadsters, with a few enclosed cars included, will be the output for the year, and at present the shipping rate is averaging 41 cars a week, so that with a productive capacity of 50, the concern can put away a few machines to meet the demand that will prevail in May, June and July. But to see 100 beautifully finished touring cars covered with dust cloths, complete with the exceptions of tires, standing on the storeroom floor, a hundred assembled motors nearby and then other cars by the score in the various departments in the stages of their development, is enough to impress the casual visitor with the immensity of the industry.

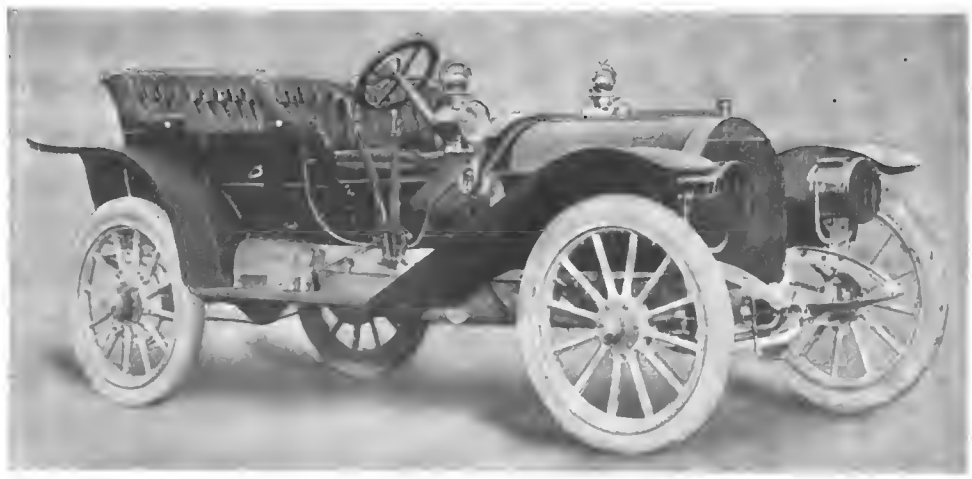
This is perhaps the feature of the prosperous condition at the Stevens-Duryea plant. In starting through in the same direction as the raw material takes from the time it enters as rough stuff until it is in the finished car, the whole aspect of the factory, extending over 300,000 square feet of floor space, is that of activity. On Friday of last week there were hundreds of cylinder castings on big trucks going from machine to machine, showing that the large number of finished cars to be shipped is but a part of the entire production, scores of transmission sets, clutches, crankcases and rear constructions, being around also, in various stages of development into parts of the cars. In the paint shop there were fifty running gears, by actual count, having the rough and finer coats placed upon them, in the finishing department there were twenty cars having the finishing touches worked up, the stripes put on them and in other ways completing them for the purchaser. Another twenty chassis were in the process of erection in the room set aside for that work, and in the assembly room there were at least twenty-five completed rear constructions, and fully 100 motor-clutch-transmission sets, all being in a unit aluminum housing, ready for lifting into the pressed steel frames standing nearby. So altogether 400 cars are in the factory, some, of course, just being started.

Yet in spite of the large number of finished cars, the great amount of work going through the factory and the building of half a hundred machines a week, the factory can give immediate delivery only upon its four cylinder models, the demand for six cylinder ones being equal to the supply. Just about an even thousand employees are engaged in the work of the Stevens-Duryea Company, and in the erecting room the men are doing evening work. A new building is being constructed to serve as a storeroom with a capacity of 70 machines.

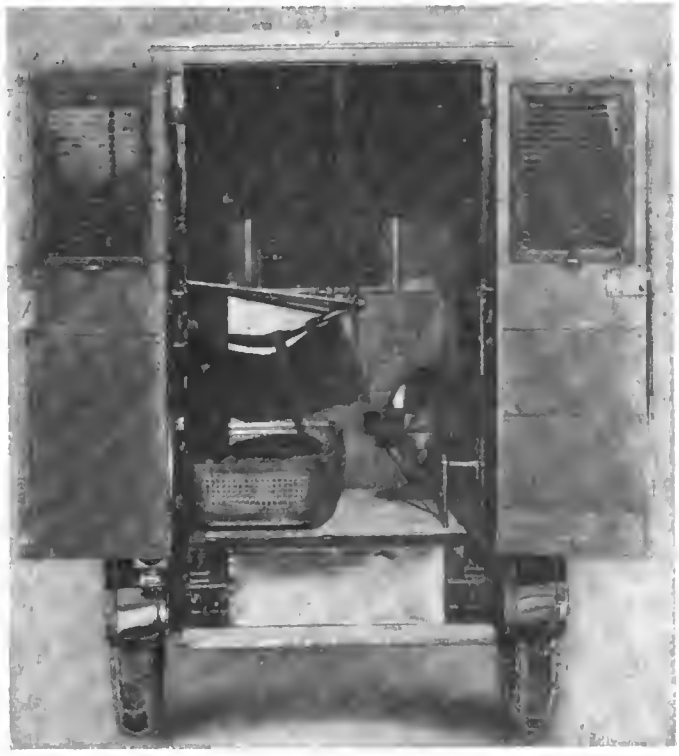
Of great interest, too, is the testing department, one of the most thorough of any automobile concern, all of the new motors being run from two to three days upon testing stands with their own carbureters and magnetos, attached to electric dynamos which accurately show the amount of power being developed. Seventeen stands are provided so that many can be tested at once. The new engines are first "run in" and limbered up by the electric motors, and then the tables are turned, so to speak, and the automobile engines, both fours and sixes, are operated under their own power, driving the electric motors as dynamos and registering the amount of power developed. When they have passed inspection, and run quietly, they are installed in their chassis and given a test upon the road from 50 to 100 miles.

Fisk Makes Four Hundred Tires Daily.

Nearby, along the canals that furnish water power, is the plant of the Fisk Rubber Company, where 400 pneumatic shoes and 600 tubes are being made daily, and more to the point, are being



Four-Cylinder Stevens-Duryea Equipped with Toy Tonneau.



Interior View of the Improved Knox Ambulance.

shipped away to supply orders, or to give the branches, agencies, or factories a stock for use when needed. The Fisk feature for some years has been the bolted on type of tire and with the new removable rim, lately introduced, the demand for this has surprisingly increased, according to the officials of the company. The bolted-on tire, fitted to the new rim combines the features of a mechanically fastened shoe with that of the quick detachable or demountable, and the increased demand for this combination has been remarkable. At present the principal business is with manufacturers who are equiping their new machines, and the amount transacted last month was double that done during February, 1908. In taxicab circles the Fisk has shown such success that the firm has received orders for this equipment from many cities, among them being Philadelphia, where the Bergdoll cabs have recently put them on. Thirty tires were shipped last week for taxicabs on the Pacific coast, and, in fact, there has been a great deal of business done through the South and West, the regular centers, such as New York and Boston, doing about the usual amount, the growth apparently being farther away from the home town.

In line with the trend toward larger diameters, the Fisk Company is now making fifty tires of 40 inches by 6, to fill an order, a remarkably big tire when it is seen in comparison with the more generally used sizes. There is a decided movement among manufacturers from small size to larger wheels, especially those from 36 to 42 inches in diameter.

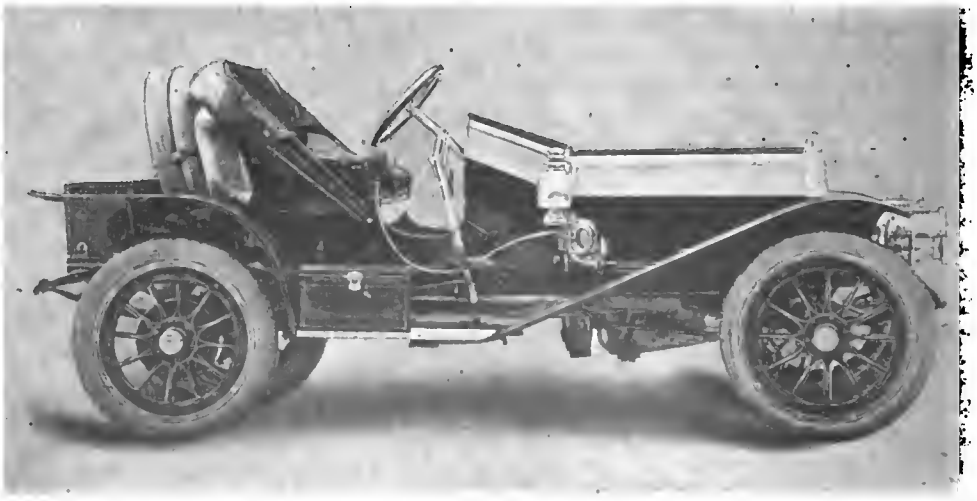
Busy Times for Knox Makers.

At the plant of the Knox Automobile Company, in this city, there is a similar scene of activity, everybody busy turning out cars, both for pleasure and business purposes, with either air or water-cooled motors, and with enough raw material going through to show the large business that will be done during the season. It takes some time to machine 300 cylinder castings, enough for 75 complete cars, and to finish these cars; and the fact that there were fully that many castings sitting in the machine shop was conclusive evidence of the plans for a whole lot of work and a big product. About 600 machines are to be put out this season, and, of course, a large number have been delivered already, a few are awaiting delivery, and a large amount of material is being constructed for the ones to come. Of the total number of pleasure cars, about 500 will be the Model O, with its 38-horsepower motor, and the other 100 will be the Model M car with a 48 horsepower motor. The trucks and commercial machines are built to order so that it is difficult to estimate at any time just how many will be built during a season.

Increased business has necessitated increase of space and now the company has 216,700 square feet, building all its own bodies, making its own aluminum and bronze castings, and doing all of its own upholstering and top building, besides the regular work of making the greater part of its cars right in the factory, very few finished parts being bought outside. A walk through the machine shop was sufficient to show the trend, for in addition to the 300 cylinders already mentioned, there were rows upon rows of pistons, ready to be machined or already finished, piles of connecting rods, bearings and small parts, galleries of crank shafts, and scores of big aluminum castings that combine the crankcase and transmission case in one. After the machine shop, located, in a room nearly 400 feet long, is through with the various parts they are sent to the stock room and out of it, in turn, to the assemblying floor in trucks, each of which carries the parts necessary for one car. This is a feature which struck one as being good and not often seen, that of taking from the stock room the four cylinders, the clutch, the valves, springs, gears, wires, spark plugs, balls, pumps, crankshaft, pistons, connecting rods and the other various parts, and putting them into separate box trucks so that each motor can be put together without there being any need for the mechanics to walk more than a yard between the stand and the supply.

The motors are all run in on stands, driven by belts, and are thus worked for about two days when their compression and freedom must be correct before they are put into the chassis and given a road test of from two to three days. Several motors were going through the various stages on Saturday morning, when the factory was visited, and a number of testing cars upon the road, but the demand for the Knox cars has been such as to prevent the firm from getting ahead and storing cars away for later use, the only ones on the floor being even then headed toward the shipping room. The body, top and upholstery rooms were all working to their capacity, while the department making the Knox glass fronts and paint shop were having enough to do.

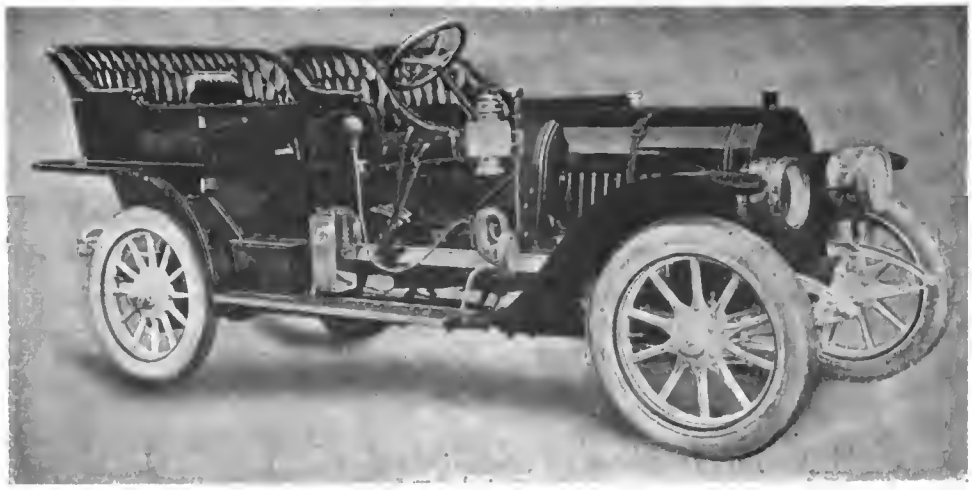
The Knox Company has always been prominent in truck work



New Body Type on Knox 38-Horsepower Chassis.

and its list of orders shows that the commercial situation is improving, there being a steadily growing demand for cars of tbis class. All types are supplied, from tbose with a capacity of 1,000 pounds to those which can carry eight tons, with motors from the single cylinder to a four or six, many of them either water or air cooled, for any use from an ambulance to a fire engine, and the big truck, that has a motor gear-driven pump at the rear, for the Boston show was receiving final touches. The fire equipment has been given especial attention and a number have been shipped recently.

The Knox Company will stick to contcsts this year as it has done in the past, entering hill climbs, speed contests on tracks and roads, endurance runs and practically everything that comes along. It has just rcccived the award of $1,000 for the winner of the Garden City Sweepstakes, on the Motor Parkway last fall, the Sharp-Arrow being disqualified.



Latest Type of Pope-Hartford—A Seven-Passenger Touring Car.

What the Hartford Factories Are Doing.

HARTFORD, CONN., March 8.—Dropping down the Connecticut Valley to this State's beautiful capital, the same note of optimism was found in the offices of its several automobile manufacturing concerns, the orders coming in a highly satisfactory manner, trade difficulties having been overcome and the only apparent purpose being to turn out cars, as fast as compatible with bigh quality.

The Pope Manufacturing Company, building tlie Pope-Hartford cars, is the largest of the concerns in the automobile business in this city, and although making 700 machincs tliis year the capacity will be the limit in 1910. Only about three months ago this concern came out from the hands of rcceivers, and its policy for this season was to a large degree outlined then, following a reasonably conservative policy. Even now there are 1,100 men employed in the big factory, one of the largest of its kind in the country, with 400,000 square feet of floor space, and evening work was announced to commence again this evening. It has been found that evening work can be gotten from the employees for a certain length of time without making them too tired the following day, or necessitating an extra shift. but then that must be stopped and the men given a rest.

An enjoyable trip can be made through this plant, to one interestcd in automobile affairs, for thcre is perhaps no concern in this line of work which makes more of its finished cars in its own factory than the Pope company does at Hartford. Its crankshafts, connecting rods, steering knuckles and other parts are drop forged in its forge shop, its radiators are made in its shcet metal department, all the castings are machined in its extensive shops and the bodies are built in still another dcpartment. The raw material can easily be followed from the sheds in the yards through the various operations of machining and fitting, to the assembling room where it goes into the cars. That there is plenty of work to do to keep the factory running full time, even if the notices of evening work were not seen, would be evident from the amount of unfinished castings seen throughout the plant, and finished ones ready to be put together are in the extensive stock rooms occupying two large fire-proof floors.

The Pope-Hartford is enjoying another year of popularity, judging from the tone of the officials when speaking of the number of shipments, the increase of incoming orders, the general good feeling existing with the outlook free from any restrictions, and the amount of material authorized sent to the purchasing department. The cylinder and aluminum castings, which are made outside of the factory, are being receivcd in large, frequent shipments and are handled in the machine shops as fast as possihle. while those parts which are made right in the plant are going through in like order. The wood frames. which have proven successful in years past, have been retained and these, of course, of second growth hickory, are securcd away from the plant but shaped in it. Sheet-metal bodies are used on all of the cars except parts of the enclosed machines, most of which, however, have been delivered, and the upholstering department, top and body department are all doing just as much as they possibly can. Only a few cars have been saved to meet any growth in the demand, but it is hoped that by getting in extra time work. a few may be finished ahead, in order to give dealers immediate deliveries. There are a large number, of course, in the factory in the different stages of finish, some almost ready to be shipped. others in the paint shops, still others in the body department. and many being assembled. Quite a squad has been employed all along in testing out the cars on the roads, after the motors have been run coupled to dynamos to record their power and to run them in, fully a dozen cars being on the road on Saturday.

The extent of the Pope-Hartford machine shops is impressive, for they are entered one after another, floor above floor, long and wide and filled with all kinds of lathes, presses, shapers, milling machines, gear cutters and others for doing special or regular operations in completing the mechanical parts of the machines. The tool shop alone, for making special tools or for keeping those in use in order, is nearly as large as the complete machine shops of some smaller factories.

Receivers Soon to Leave Electric Vehicle Company.

Further up Capital avenue is the plant of the Electric Vehicle Company, makers of the Columbia cars, soon to be free from the receivers and able to pursue a more aggressive policy than it has done for some time, according to Henry C. Knuckols, one of the receivcrs. In about two months' time the recciversliip will be dissolved and the reorganization completed. At the present time, however, it is pursuing a plan of building 400 gasoline cars and 100 electrics, on an average of 12 to 15 cars a week, with 500 employees working full time. Of course, as soon as the concern is out of the receivers' hands it will start to build more cars for the 1910 season, and already material for the new product is being arranged, the details having been worked out, and the new cars with some altogether new features will probably be upon the roads by the middle of April.

One of the attractions at the Madison Square Garden show was the color combination at the Columbia booth, a white and a cream yellow car, each receiving a great deal of attention, and so the question was asked as to whether there has been a demand for fancy colors, especially the lighter ones. From the answer it is evident that there is a desire for such machines, for three white ones have been sold here in Hartford, one in Chicago, two yellow ones in other places and a number of prospective purchasers are contemplating having cars gaily finished. The five-passenger touring car, as is generally the case, is the popular

model, though the four-passenger one with a detachable tonneau is being sold in many sections of the country.

Large Production of Hartford Rubber Works.

Working its big factory 24 hours, and turning out 400 shoes and 600 to 800 pneumatic tubes, 2,200 bicycle tires and 200 solids every day, the Hartford Rubber Works Company is doing an enormous business and one that directly reflects credit upon the automobile industry, for the large number of cars that will be built will require tires, and from the demand in the factories of these goods can be seen the stride being taken by the motor-vehicle builders. Both the pneumatic and solid business has been increased during the early part of this year, and the full day and night work has been required to meet the demand.

The newest of the concerns engaged in the automobile business around this city is the McCue Company, which is building a standard car bearing that name, equipped with a 29-horsepower, four-cylinder motor, a three-forward speed, selective sliding-gear transmission and a full floating rear axle. A four-cylinder motor of 45 horsepower can be supplied at an additional cost. Two types of bodies are supplied, either a five-passenger roadster or a four-passenger roadster. The construction throughout is that followed in generally accepted automobile construction, and at present the company is carrying on its work in a small machine shop while waiting for the completion of its factory, to be finished during the latter part of this month. It is planned to build from 150 to 200 cars this year and to increase that number to the limit of the new plant for the 1910 season.

TREMENDOUS TAXICAB INCREASE IN PARIS AND LONDON

PARIS, March 3.—Paris is cursed with a multiplicity of taxicab fares which the authorities are powerless to remove. In order, however, that the public may no longer remain in ignorance as to why a fixed journey in three different cabs should cost three different prices, the Prefect of the Seine has ordered that on and after April 15 all taxicabs shall carry the price per kilometer marked on the flag at present bearing the word "libre." This price will be the one charged after the initial fare of 15 cents has been paid. The distance to be covered for the minimum initial fare, and which at present varies from 600 meters to 1200 meters, must be indicated on a metal plate carried by the side of the driver. Thus a cab running 900 meters for 15 cents would have this indicated on the side plate. If the following rate were 4 cents per additional 400 meters, the flag would carry the figure corresponding to 10 cents, this being the rate per kilometer. Cabs at present vary so much in power, comfort and fittings that it is impossible to enforce the same rate of payment for all, regardless of equipment.

The number of taxicabs in circulation in Paris at the end of 1908 was officially declared to be 2,923, while the number of horse cabs at the same period was 8,790. Twelve months previously, at the end of 1907, taxicabs numbered 1,465 and horse cabs 9,608. Automobile cabs have thus doubled during the twelve months, while the number of horse cabs shows a serious decrease. The decrease of the horse cabs, however, is not in the same proportion as the increase of the motor cab, for it must be remembered that the latter does at least 30 per cent. more work than the former is able to accomplish.

Though Paris holds the lead with the number of taxicabs in use, it is very closely followed by London, which at the end of 1908 had 2,805 taxicabs in regular service, compared with 723 twelve months previously, and only 96 at the end of the year 1906. The decline of the horse and the increase of the taxicab in the city of London since 1903 is remarkable, as is shown by the following official figures:

	Horse Cabs.	Motor Cabs.
1903	11,404	1
1904	11,057	2
1905	10,931	19
1906	10,492	96
1907	9,818	723
1908	8,475	2,805

As in New York, the use of the taximeter as a recording instrument was unknown until the automobile cab made its appearance. This doubtless accounts for the sudden jump into favor, the London public appreciating a system which made payment a matter of clockwork. In Paris, on the other hand, the taximeter was an established institution long before automobile cabs made their appearance, and when these latter did appear they had to compete against a low rate of fares applied with mechanical accuracy to horse-drawn vehicles.

The number of motor omnibuses in use in London at the end of last year was officially declared to be 1,133, this being a slight decrease on the number in service twelve months previously. The comparative figures, as given in the official returns, are as follows:

	Horse 'Buses.	Motor 'Buses.
1903	3,623	13
1904	3,551	31
1905	3,484	241
1906	2,964	783
1907	2,557	1,205
1908	2,155	1,133

The number of motor 'buses in service in Paris at the end of 1908 was 162. The company responsible for the service in the French capital holds a monopoly, but is under an obligation to replace all horse 'buses by automobile vehicles during the year 1910.

AGRICULTURAL MOTOR COMMISSION FORMED.

PARIS, March 4.—A new commission has been added to the half dozen of which the Automobile Club of France is practically composed, the new body to be known as the Agricultural Commission. Its object will be to encourage the application of the automobile and internal combustion motors to agriculture, this being a field of activity that has hitherto been much neglected in France. In view of the possibilities of usefulness in the matter of agriculture, it has already been decided to hold an exhibition and practical tests annually for the next four years, the district chosen being a different one each year, in order to diffuse knowledge on this subject and arouse interest all over the country. The acquisition of a field for experimental work with motor-driven agricultural machines has already been decided upon, the field to be of such a nature that it can also be employed for aeronautical experiments.

FRENCH COMMERCIAL TESTS OCT. 15-NOV. 15.

PARIS, March 4.—The next commercial vehicle competition of the Automobile Club of France will be held from October 15 to November 15 of the present year, the center to be at some point in the suburbs of Paris, and the route to consist of circular trips from this center. Special importance is attached to the competition from the fact that it will be held under the auspices of the War Department, and partly under their regulations, the Army having decided to offer a substantial indemnity to all commercial vehicles conforming to the successful type evolved from the competition, on condition that the automobiles shall be at their disposition in time of war. As army officers will in all cases be responsible for the control, there will be much more rigorous treatment than usual in tests of this nature.

There have been a number of makers in this country who have desired this very important test.

SAFETY AND UTILITY OF AUTOMOBILE STEERING SYSTEMS

Thos. J. Fay.

PART I.

RAILWAY equipment does not have to be provided with steering gear, for the reason that the wheels are flanged in such a way that they will not run off of the steel rails over which they are designed to roll. Horse-drawn vehicles are not provided with steering gear in view of the manner in which the horses draw the vehicles along, thus making it necessary to

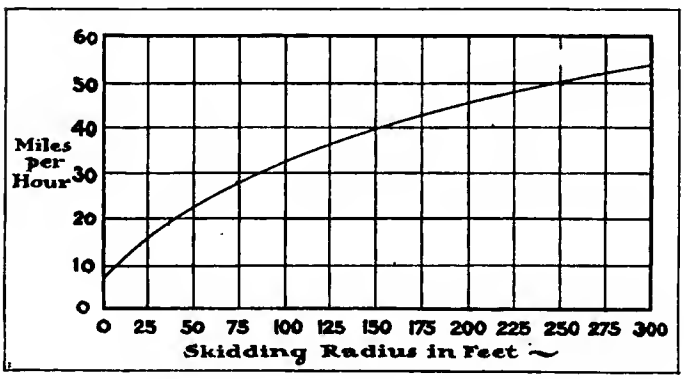


Fig. 1.—Showing relation of speed of cars to skidding radius.

guide the horses instead of the vehicles. In automobiles, however, the principle is different; they are propelled, not drawn, nor do they roll over guiding rails; hence they have to be steered.

According to Newton's "first law of motion," even automobiles would not have to be steered on a hard level roadway were the automobiles of a harmonious design, and provided they were always to travel in a straight line, for the law says: "If a body be at rest, it will remain at rest; or, if in motion, it will move uniformly in a straight line till acted on by some force. That the secondary force must not be parallel to, and in the same direction, as the force which impels the car, is true.

But one of the advantages of the automobile is that due to its mobility in all directions despite the law, which urges it forward in a straight line. On the other hand, the ability to direct a car out of a straight line does not defeat the tendency of the same to hold to a tangent, and it is for this reason that it is dangerous to overstep the bounds beyond the ability of the devices available to control.

Stable conditions are present in a car when it is traveling in a straight line. Instability begins with the first turn of the steering wheel and increases as the angle of the road wheels is increased, which instability is also augmented as the speed is increased. That some cars will perform better than others, in this respect, is assured, if only it is true that all cars are not with the same center of gravity and in general harmony.

The first serious sign of instability, when a car is diverted out of its habitual straight course, is when the skidding tendency is noticeable. Fig. 1 depicts the situation under good average conditions, in that it shows the relation between speed of the car, in any given case, in miles per hour, and the radius of the arc of a circle through which it can be directed, within which, skidding will not take place on a hard, level road, in the absence of accidental outside influences.

In the curve, Fig. 1, absassa represent speed in miles per hour, and the ordinates are given values in feet, representing radius of turning, under conditions of eminent instability, as indicated by skidding. If a car is traveling at 40 miles per hour, the curve shows that the intersection with the ordinate representing the skidding radius will be at 150. In a word, then, if a car is traveling at a speed of 40 miles per hour, skidding will ensue if the radius of turning is 150 feet.

In actual practice, considering streets of the average width, Fig. 2 shows the usual performance, in turning corners, and the radius of the arc of the circle is given as 75 feet. In this case the curve, Fig. 1, indicates that skidding will take place at about 38 miles per hour of the car. The manner in which the corner is turned, as shown in Fig. 2, is not looked upon as good practice by many autoists, and Fig. 3 is offered to illustrate the proper way to go around corners, according to some authorities. In this case the autoist is supposed to keep to the right, and in so doing the radius of the arc described in turning will be about one-half of that which will be due to cutting the "in-curb," as represented in Fig. 2.

To go around corners in the manner as shown in Fig. 3, it is necessary to slow down, for the reason that the radius of turning will be less, and, as the curve Fig. 1 tells, skidding will follow if the speed is 18 miles per hour, assuming the radius is 37 1-2 feet. Likewise, for every speed of any automobile there is a maximum rate at which the turn can be made without skidding, and safety demands that skidding be avoided. Skill in driving consists in knowing and maintaining safe speed, taking into account (a) the fundamental laws and their effects, (b) the road condition, which introduces "accidental" variations, tending to distort normal performance.

Front Wheels Must be Set Properly.—Makers of automobiles, if they have in mind the best results, take into account the manner in which turns have to be made in order to avoid skidding on the one hand, and undue tire depreciation on the other. This is not to say that makers of cars can do anything about the skidding question if the speed is higher than the law allows for a given radius of curvature, in view of the effect of

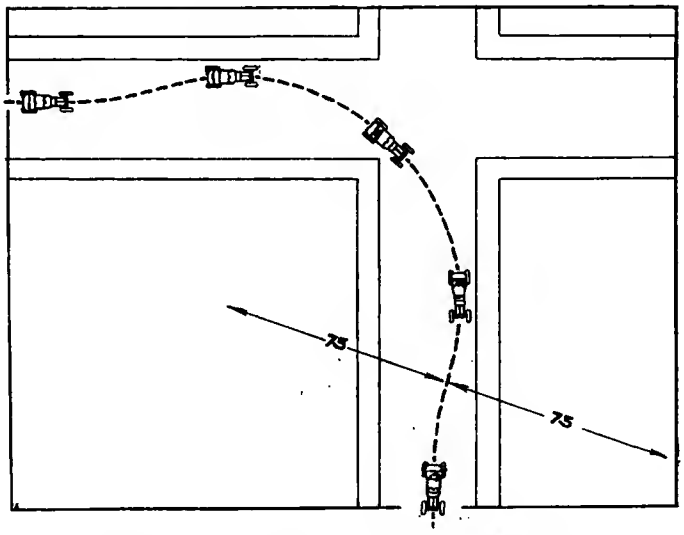

Fig. 2.—Corner clipping orbit of the average driver.

centrifugal force, as previously stated. What the makers can do is to avoid certain tendencies, within limits.

Ackerman, in the eighteenth century, discovered that a vehicle, on a curve, to perform properly, had to be provided with such tierods for the front wheels as would enable them, respectively, to roll on independent orbits, not to a common radius, but from a common axis. Fig. 4 is offered to illustrate the point

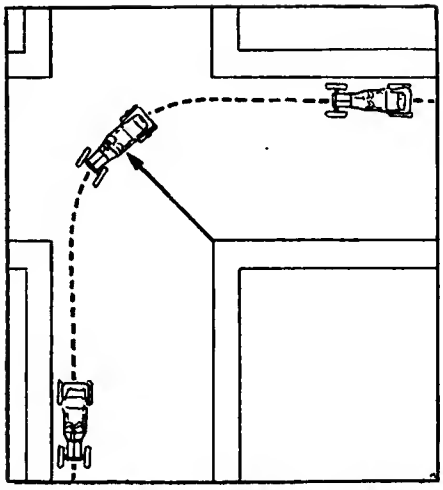

Fig. 3.—In legal driving keep to the right.

to be made, in which it is shown that true rolling motion of all the wheels will be realized when the car is going straight ahead. When the wheels are canted, as in negotiating a curve, if the tierod arms are parallel, since they are connected by a rigid tierod in practice, the radius O A will be the inner wheel radius C C', of turning, but the outer wheel will cant to the same angle, and the arc S S' will be described, which arc is not parallel to the arc C C', and the wheels will not roll perfectly; in fact, the outer wheel will drag.

But if the dragrod arms are to the rear of the axle and converging, in the manner as will be presently shown, it is then that the two front wheels will roll on parallel orbits to a common center, O, Fig. 4, and the inner wheel will have a radius O A, while the outer wheel will have a radius of turning O B. As the figure shows, the arc R R' is parallel to the arc of the circle C C', under which conditions the wheels will perform their functions without dragging, and the tires will avoid damage in the process, because parallelism will be maintained.

Ackerman-Jeantaud System of Steering.—This definite advance over the original idea of Ackerman is illustrated in Fig. 5, in which the arms O L and O' L of the ticrod L L converge to the rear, and are parallel to, and cut by, the line A L O on the right side, and A L O' on the left side. The point A is at the center of the rear axle. In turning, the point A moves out on the rear axle plane to the point A', with the result that the turning radius of the car becomes that of the radius A' O' for the inner wheel, and the radius of turning of the outer wheel becomes A' O, so that the two canting wheels turn on parallel orbits around a common axis, A'.

Obviously, the arms L O and L O', instead of converging to the rear, would serve just as well if they were made to diverge to the front, provided only they be designed to remain in the same plane as a projection of the line A O for L O and A O' for L O'. This is not always possible in practice, because the spokes of the road wheels are in the way.

Characteristic Illustration of Common Practice.—Practice leaves its earmarks on everything, and the Ackerman-Jeantaud system of steering gear is no exception to the rule. In some shops the manner in which the problem is dealt with is illustrated in Fig. 6; one of the advantages is due to greater accuracy in the cases involving a turning radius of more than that due to 30 degrees cant of the steering road wheels.

Considering the diagram, Fig. 6, it is first necessary to decide upon the governing conditions in practice. If it is true that the average turning radius is, say, 75 feet, as given in Fig. 2, this is the distance to use in the diagram Fig. 6 as the value of O A. The distance b equals the wheelbase of the car, and a is equal to the distance between the two pivots of the right and left steering knuckles. Thus far it has not been necessary to do any figuring, and all that remains is to fix upon the angles m and n.

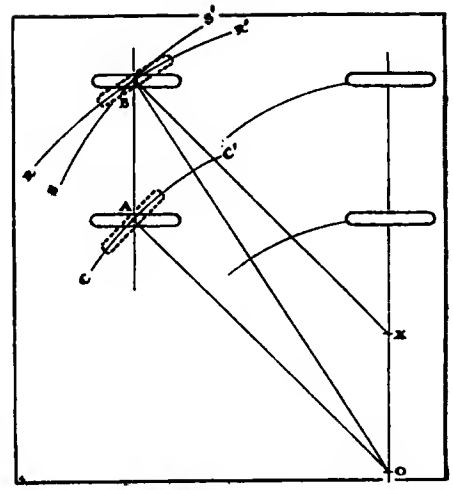

Fig. 4.—Tendency of wheels to drag.

It will be remembered that the radius 75 feet is not the turning angle of least radius; it is the most likely radius, all things considered. Under the circumstances, to be able to establish the relative angles, m and n, it is to proceed as follows:

$$(1)\ldots\ldots\cot m = \frac{AC}{CO};$$

$$(2)\ldots\ldots\cot n = \frac{BC}{CO};$$

$$(3)\ldots\ldots\cot n - \cot m - \frac{a}{b} = \frac{BC - AC}{CO};$$

$$(4)\ldots\ldots\cot n = \cot m + \frac{a}{b}.$$

Tabular Values Save Calculations.—While it is always desirable to know the method by which results are arrived at, it is important to see things as in a "bid's-eye view," in order to realize something of the relative advantages. Then, it is to avoid mistakes if tabulations are made, since they can be done on a leisure basis and mistakes can be discovered and corrected. With these advantages in the mind's eye, the tabulation here offered takes into account the several likely canting angles of the steering road wheels of automobiles, and the effect of the length of wheelbase may be seen at a glance.

As an illustration of the use of the table, it will be enough to call attention to a car with a 100-inch wheelbase, which shows beneath a 15-foot turning radius if the wheels are canted 45 degrees from the center. In like manner it will be possible to fix upon the turning radius, in feet, for all cars up to 116 (inclusive) wheelbase for all canting angles between 34 and 46 degrees from the center.

Importance of the Equalization of Power.—While it is true that the question of steering is ordinarily regarded as a simple operation, in which guiding the car is the main feature,

TABLE SHOWING THE SHORTEST TURNING RADIUS OF AUTOMOBILES.

Angle of Inner Wheel Degree	Length of Wheelbase in Inches and Turning Radius in Feet												
	92	94	96	98	100	102	104	106	108	110	112	114	116

36	17	17	17.5	18	18	18	18.5	19	19	19	19	19	20
37	16.5	17	17	17	17.5	18	18	18	18.5	19	19	19.5	20
38	16	16.5	17	17	17	17.5	18	18	18	18.5	19	19	19
39	16	16	16	16.5	16.5	17	17	17	18	18	18.5	19	19
40	15	16	16	16	16.5	16.5	17	17	17.5	18	18	18	18
41	15	15.5	16	16	16.5	16.5	17	17	17	17.5	18	18	18
42	15	15	15.5	16	16	16	16.5	16.5	17	17	17.5	18	18
43	15	15	15.5	15.5	16	16	16	16.5	16.5	17	17	17	18
44	15	15	15	15	15.5	16	16	16	16	16.5	17	17	17
45	14.3	14.5	15	15	15	15.5	16	16	16	16	16.5	17	17

Note.—The distances in feet in the body of the table are given in the nearest (above) feet, and fractions of feet, on the ground that further accuracy would be uncalled for.

it is nevertheless useless to go through the process unless the car will mind the helm, so to speak. The steering wheel is almost the least device to be given consideration in the process.

The power is delivered to the traction wheels, usually the rear wheels of the car, and since the two traction wheels do not always travel at the same speed, some means must be provided by which the power can be equalized. If the power is not equalized, it is then that skidding will be likely, since the ability of each of the wheels is limited, and each must do its share.

But the share of work that must fall to each traction wheel is a variable depending upon the road conditions, speed of the car, curvature of the road, centrifugal force, and all the other tendencies such as will cause the traction wheels to press more or less. If the load is equal on both wheels, and if the road is of the same texture under them respectively, then, if the car is on the "straight ahead," it is a fair inference that the power requirement will be the same for both of the traction wheels.

Unfortunately, there are the conditions under which the steering wheel will be the least needed; the car should tend to maintain its straight course, as previously stated, and it follows that when the steering gear is used the conditions of its use are quite different.

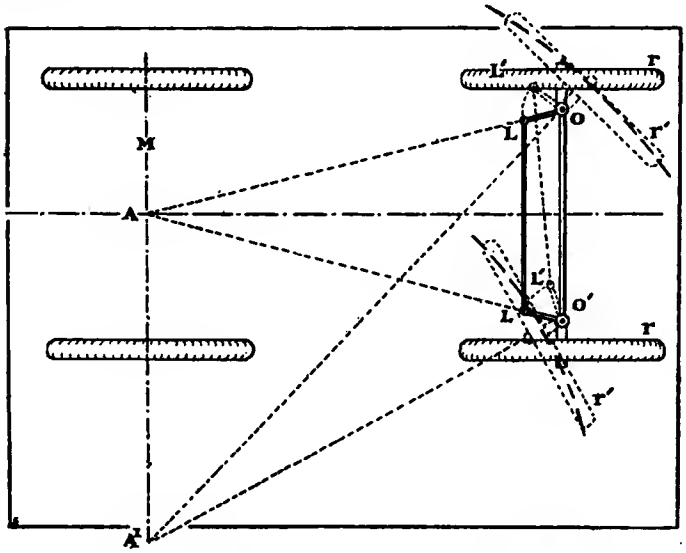

Fig. 5.—Characteristic Ackerman-Jentaud steering layout.

In order to be able to deliver the power in proportion to the respective abilities of the two traction wheels, it is the custom to use compensation gearsets (differential gears), which may be of divers designs, as square-cut or bevel types of gears. At all events, the purpose of the "differential" is to correct the evil tendencies, and, in a large measure at any rate, the use of the "differential" results in the equalization of the delivery of power to the respective traction wheels, thus aiding in the steering process, since skidding is aborted.

The complex nature of the "differential," and the curiosity it arouses in the haunts of owners of automobiles, demands an explanation of its peculiar action, at this time, on the ground that it is of great importance in connection with the steering operation, since it assures that a car will respond to the will of the operator as expressed by the steering wheel. Fig. 7 shows the arrangement of a bevel type of differential gear, in which A represents the bevel pinion which, in conjunction with its mate B, transmits the power of the motor to the differential housing C. Tracing the transmission further in its migration, it is to note that the spider D D serves as the means and the axis of rotation of the "satellites" E and E', through which the distribution is made to the gears F and F', which, in turn, are keyed to the differential shafts G and G', which shafts are in rigid relation to the traction road wheels.

The one remaining question is, How does the differential perform the distribution in delivering power to the respective traction wheels in proportion to their respective needs? Considering the source of torque to be the motor, which causes rotation of the pinion A, it is self-evident that this pinion, since it meshes with the gearwheel B, will compel rotation, and the direction will be as shown by the arrows, thus assuring that the housing of the differential gears will rotate in response to the motor, and to this extent there is no differential action whatsoever.

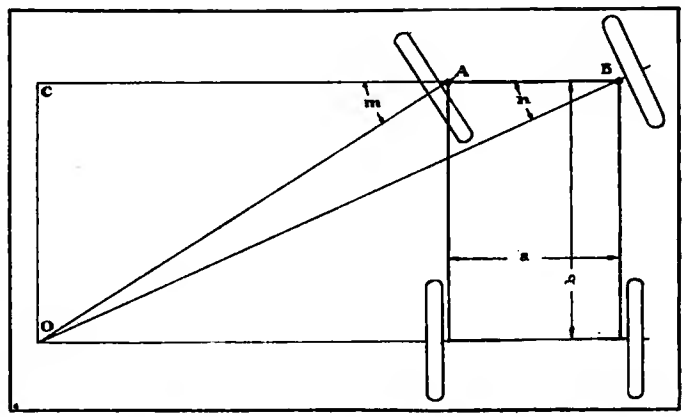

Fig. 6.—Practical method of laying out steering linkages.

Since the satellites E and E' are free to rotate on the spindles of the spider D D, and considering that the spider D D is free to rotate on the bearing over the shafts G G', the satellites are free to respond to the tendencies in the manner as follows: (a) When the car is on a straightaway, the satellites merely serve as a balancing arm, weighing out to the planets F and F', equal increments of torque, and both road wheels rotate at a common speed, during which period the satellite pinions do not rotate, with their spider, around G G', nor will the same satellite pinions E E' rotate on their own bearings on the spindles of the spider D D. The whole housing rotates instead. (b) But if the car is negotiating a curve, it is then that the differential will have a function to perform, since the road wheel, on the inside, will make a less number of revolutions than the remaining road wheel. The result is that the speeds of the planets F and F' will not be the same, and during this time compensation will be due to rotation of the satellite pinions E and E', not only on the spider spindles D D, but the spider will also rotate on the shafts G and G'. During the period of this relative motion the ability to deliver power is in no way interfered with, and while the road wheels are enabled to revolve at different speeds, they are also driven, respectively, without cessation of torque, although it is true that the wheel traveling the fastest will measure the greatest result in horsepower.

What happens under other conditions, as on bad roads, is a matter which will not be taken up here, nor will certain other possibilities of the differential gear be interjected, on the ground that the situation would be unduly complicated. The point to be made here is that it is the action of the differential gear which enables cars to roll around curves, delivering power to both wheels without altering the "slip" relation of the wheels.

(To be continued.)

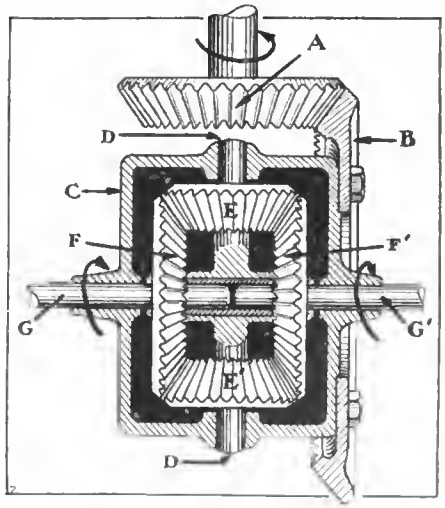

Fig. 7.—Bevel differential gears set.

HOW ONE AGENT VIEWS THE SELLING PROPOSITION

By A. D. HARD, MARSHALL, MINN.

THE methods now in use by which automobiles are finally sold to actual users by local agents does not differ much from those by which any valuable piece of merchandise is marketed. But back of the final sale, the plans by which the manufacturer places his product is the hands of dealers is peculiar to the automobile business alone. Men of considerable business ability have tried to evolve a scheme of selling by means of which certain evils might be eliminated and advantages secured, but from careful observations and investigations made for the purpose I am convinced that they are at present following plans which must very soon be altered or abandoned.

In my investigations I have commenced at the retail end of the selling proposition and worked backward toward the manufacturer. The scope of my observations includes only several small cities in southwestern Minnesota and western South Dakota. The roads in this region of country in their natural condition are favorable for automobile use a greater portion of the year, and the people are above the average in wealth and refinement. They have money with which to buy pleasure, and they get it in automobiles. Outside of physicians and real estate agents, nearly all automobiles are used as luxuries.

A farmer will quit the plow at 3 o'clock, and, getting into his four-cylinder car, come to town to talk politics. The business man of the small towns will get out his touring car after business hours and take his family and friends to the city, thirty miles away, to attend the theater, and the women of the family will use the car as much or more than the men themselves.

The small city of Flandreau, South Dakota, with a population of less than fifteen hundred, has 54 automobiles, and one of them cost $8,000. Madison, a similar sized city, some thirty miles west, has 42; Pipestone, twenty-two miles east, has over 30, and Luverne, a city of about twelve hundred, is the manufacturing home of the Luverne automobile, an assembled two-cylinder car of some pretensions.

The men who sell automobiles as local agents as a rule are much less able to to own an automobile than those who buy for their own use. They cannot keep several cars in stock, therefore they sell from catalogs and demonstrations made by State agents in Sioux Falls or Minneapolis. In many cases the agent who sells the car is not the credited agent of the car that he sells, but by a bargain between him and some agent of that car in some other town nearby he is able to handle the sale and clear 10 per cent. profit. Agents in several nearby cities combined to accept one agency on the deposit-contract system, and then divide up the cars to suit themselves. This enables the agent to supply a customer with almost any car that he may prefer and still make as much net profit as though he was selling the car that he has the agency for. But the local agent does not sell many of the cars that come to town. Several men who wish to buy cars will get together and arrange for one of their number to take a deposit-contract agency, and each gets his car at wholesale price. The agency is then not pushed at all, and, as no other agent can be given a contract in that town, no more of that make of cars are sold in that place.

It is a very easy matter for agents in several nearby cities to bunch their orders, and the manufacturer wonders why he is not able to secure a deposit-contract agency and send more cars into that territory. The State agent does not feel the loss, as he puts out all the cars that he has deposits on, and, as the demand at present is about equal to the possible supply, he is satisfied with the big discount which the manufacturer has been compelled to give, in order to get him to handle this system of selling. One reason that agents are combining to evade the restrictions of this deposit-contract system is because the proportion of the 30 per cent which the manufacturer sets off for the middlemen is divided in such a way that the man who works to make sales and takes risks not asked for in other lines of business gets but one-half the profit of the sale. His 15 per cent is further cut into by the various expenses of the business until a paltry 10 per cent is left as profit on a sale that it takes months to make.

Under these conditions, which do not apply to large cities, an agency for automobiles is not a very alluring proposition. The ultimate effects of the combinations of single buyers and trading in agency products comes back to the manufacturer. It does not affect the State agent very much, as the cars that reach any customer comes through his hands and drops 15 per cent in his pocket, no matter whether they go to clubs or to a bunch of agents represented by one contract. The local agent has not made many sales, nor has he made much money in the business, and he loses all interest in pushing the business next year. The next year the manufacturer will begin to realize that he has not only sold his cars at a big discount, but the discount given has not resulted in building up a permanent or reliable demand because the local agents are not pushing sales.

Already the deposit-contract system is beginning to disintegrate by secret evasion of the restrictions by manufacturers and State agents, in order to get ahead of competitors. I have on my desk a letter offering to waive the deposit clause and allow me to get cars for spot cash as wanted, one at a time.

One of the largest manufacturers of automobiles in the United States has just sent one car here to a party at wholesale price for private use on an open agency proposition. Five persons here have formed a club and taken an agency for a well-known car in order to secure the 15 per cent discount on their own private cars.

THE DIFFERENT IMPORT DUTIES ON TIRES

WHEN auto tires are imported as tires in shipments of tires the customs duty upon them is 30 per cent., but when they are brought into this country in the same crate as an automobile, even though they have never been put upon the wheels of the car, the rate is 45 per cent. This is according to a decision made last week in the United States Court of Appeals in New York upon a case appealed from a similar decision by the Circuit Court by the Auto Import Company, of New York City, which had received a shipment of automobiles in which the tires were simply enclosed in the same crates, but had never been fitted to the wheels of the cars.

This company brought up the test case, holding that the tires should be taxed at a tire rate, but this contention was overruled by the court, it being held that automobiles and their tires are entireties. In making this decision, Judges Lacombe and Ward concurred, but Judge Noyes dissented, giving as his opinion that inasmuch as it was problematical as to whether the identical tires which were received in the crate would ever be put upon that car, they should be received at the lower rate, there being an appreciable difference in the case of four expensive shoes and tubes.

As a result of the pending enforcement of the German liability law, at present before the Imperial Diet, every class of persons professionally interested in motor cars have united into one great opposing force, as all regard the measure uncalled for, untimely, ill-advised, and a severe handicap on the industry, which is just again collecting its strength after the universal financial crisis.

Letters Interesting and Instructive

DIRECT ON THIRD AND FOURTH SPEED.

Editor THE AUTOMOBILE:

[1,782.]—(a) I have read about a car in which the transmission gear set is devised for "direct drive" on the third and fourth speed. Please illustrate the idea.

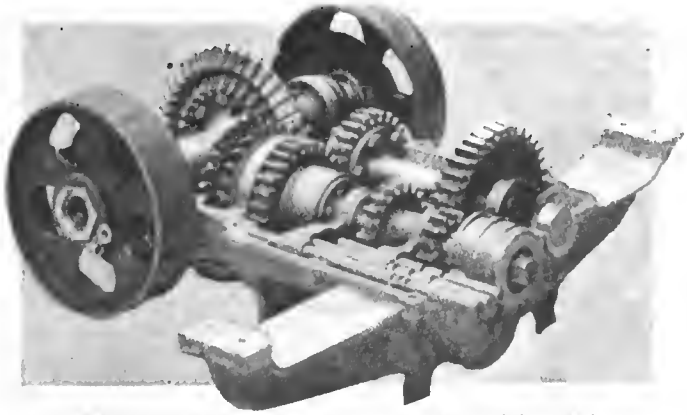
(b) Does the speed of an automobile motor depend upon the sizes of the valves?

(c) Are the articles by Thomas J. Fay to be published in book form, and, if so, when?

Ishpeming, Mich. C. A. S.

(a) The "Berliet" is one of the cars so designed that the transmission gearset is contrived for direct drive on the third and fourth speed. The plan is as shown in the illustration here given. As will be seen, two bevel-gear sets are used, and, since they are sleeved, it is possible to shift the one or the other at will for the purpose.

(b) The speed of a motor will increase as the result of larger valves, more commodious passageways, higher compression, better timing of the valves and the spark. Also if the design can be improved so that the mechanical efficiency will be on a higher level. It is assumed that you mean that the power should increase as well. There are limitations to the increase that can be realized since pre-ignition will follow if the compression is increased beyond a certain point, which might be about 95 pounds per square inch, absolute. Then, it is true that valves will warp if they are too large to withstand the heat changes and the strains which follow.



Berliet, Illustrating Direct on Third and High Speed.

(c) A date cannot be fixed for the issue of the writings of Thos. J. Fay in book form.

RELATION OF GEARS TO TIRES.

Editor THE AUTOMOBILE:

[1,783.]—Will you kindly tell me in "Letters Interesting and Instructive" which type of transmission—planetary or sliding—is the better, from the point of view of endurance, and if the planetary is easier on tires; also, if it is true that speed changing is attended with jerks, if sliding gears are used?

Allentown, Pa. TRANSMISSION.

The planetary has a certain useful range in automobile work, and while this zone, if such it might be called, has been invaded by the sliding gear system, it is true, nevertheless, that the planetary system has held its own. On the other hand, the sliding gear system is of undoubted ability, capable of serving in the most exacting work, and it is highly improbable that any concrete comparison between the two types of transmissions will be of any value. From the tire point of view the more speed changes there are the better. But the planetary furnishes the equivalent of speed changes in starting a car, since the bands can be slipped.

FIERCE ACTION OF MULTIPLE DISC CLUTCH.

Editor THE AUTOMOBILE:

[1,784.]—Please tell me what to do to stop "chattering" in my multiple-disc clutch, when the car is starting from rest. The clutch appears to slip harshly, through a small arc, let go, and repeat, several times, in rapid succession at certain critical points during the engagement process. The clutch seems to be of ample proportions as it does not slip in regular running when the lubricant used is not too thick. The thrust bearing is in good shape.

This "chattering" is destructive to the car and annoying to the occupants. As the makers have no suggestions to offer I will be obliged for your solution of the difficulty. R. R.

New York City.

For some reason the engaging pressure is too abrupt. This could be due to discs of small diameter, brought suddenly into high-pressure by a stout spring. The oil used probably is not the best for the purpose, it is too thin, that is to say, it has not the requisite body. Then, it is too persistent. For clutch lubrication the oil must possess peculiar properties which are not generally well appreciated. What you will have to do is to select a lubricant for the clutch in which the properties will be about as follows:

(a) The body of the oil will have to be pronounced; a fairly heavy cylinder oil, such as will answer well in the cylinders of your motor, will serve the purpose.

(b) This oil, alone, will be of very little value for the purpose, for the reason that it will not squeeze out excepting under very high pressure, and even then it will "flatten" to a very thin film, rather than squeeze out. To give this oil the property of primary lubrication, and to afford it the facility of running out from between the discs, after it has served the purpose, involving a time element in the process of accelerating, it will be neccssary to add kerosene.

(c) The amount of kerosene to add, cannot be stated definitely in the absence of information in relation to the lubricating oil which may be used and certain clutch-mechanism characteristics having bearing upon the performance.

(d) In usual cases it is the custom to use cylinder oil and kerosene in equal parts and the results seem to be very good indeed.

In the mean time it is not proper to "slam" the clutch into instant engagement. Nor should the motor be "raced" at the moment of engaging the clutch. The transmission gear set is provided with speed changes for the purpose of enabling the acceleration to take place in gradual increments; unless advantage is taken of the presence of the speed changes it is assured that they are either useless appendages or, they should be used for the intended purpose.

Finally, if the clutch persists in its "fierce" action after the lubrication is adjusted, it is the spring that will have to be modified in some way, in order to give it more limber properties, but the chances are the spring will not have to be touched if the lubrication is properly adjusted and if the car is properly driven.

THE KERNEL IS UNDER THE HUSKS.

Editor THE AUTOMOBILE:

[1,785.]—You say: "There is no occasion for having a full complement of balls, if the bearings without a full complement are properly selected." It will be interesting to know exactly what you mean by this expression. How would you proceed to properly select a bearing without a full complement of balls that would be more effective than a bearing with a full complement?

You say further, "You show utter lack of knowledge of the subject in thus attempting to maintain that a ball bearing increases in ability in direct proportion to the number of balls used."

According to Stribeck,

$$P = kd^2 \frac{Z}{5};$$

Where k is a constant depending on the properties of the material and the form of the ball race.

d is the diameter of the ball.

Z is the number of balls.

Now, let us take two bearings made of the same material and having the same form of race and the same dimensions, both of the balls and races. Then, if Z_1 and Z_2 are the number of balls in each bearing, and P_1 and P_2 the corresponding carrying capacities, we have

$$P_1 = \frac{kd^2}{5} Z_1;$$

$$P_2 = \frac{kd^2}{5} Z_2;$$

and $\frac{P_1}{P_2} = \frac{Z_1}{Z_2}$; or, in other words, the carrying capacities of the two bearings are directly proportional to the number of balls.

New York City. ASHER GOLDEN.

The difference between the facts as depicted by Stribeck and your version lies in the license you take with the figures. You cannot, in a given set of raceways, increase the number of balls, unless the diameter of the balls are decreased. Under the circumstances it would seem as if the use you make of the formula is quite beyond its normal scope. Then, there is a certain irrelevancy about the example you cite which is so self-evident as not to require further discussion.

BALL BEARINGS DEPEND ON ACCURACY.

Editor THE AUTOMOBILE:

[1,786.]—In the discussion now going on in your columns in regard to ball bearings, it eeems as if eeveral material points have been overlooked thus far, or at ieaet have not found expression in type. The load carrying capacity of a ball bearing depends not only on the number of balls, but also on the accuracy of both balls and races. Given a bearing with balls exactly epherical and uniform in size to the last thousandth of a millimeter, running between races every element of which is a perfectly true circle; assuming also that the balls and the races are of uniform hardness over all the contact surfaces, it follows inevitably that the load carrying ability of the bearing will bear some rough relation to the number of balls used. This, of course, on the aesumption that the balls and races are of the same size in both casee.

Furthermore, the life of the bearing will be increased in substantially similar proportion for equal loads. It ie a known fact that even the best ball bearings wear somewhat, although the wear ie very small. When analyzed this simply meane that each revolution of each ball represente a certain minute wear, whose amount, other things being equal, will bear some relation to the load the ball eustains. Reduce the load per ball by multiplying balls, and the life of the balls will be increased; though possibly this may not hold true of the races, since, what is saved in wear per ball revolution ie lost by the greater number of balls going around in a single revolution of the shaft. Incidentally, the same reasoning showe why the life of a bearing is shorter under high than low speeds for equal loade. The wear is simply proportional to the total number of revolutions in the given time.

From the above it follows that if the balls and races are not sufficiently accurate to distribute the load, little is gained by adding balls, eince three balls at most will carry the entire load. In other words, the load cannot be distributed among a larger number of balls than three, and it may be borne wholly by a single ball, which must be strong enough to reeist crushing. In thie case, the only gain from multiplying balls ie that the load is transferred more quickly to fresh groups of balls, so that an individual ball carries its maximum load through a smaller arc of revolution.

In a word, the queetion of load-carrying ability and endurance cannot be divorced from the question of accuracy in size. If the limit of error is well within the compreeeibility of the balls and races under the loads they sustain, this minute compression will suffice to transfer excessive loads from the larger or irregular balls to the smaller or more uniform balls.

The etatement of Mr. Golden in your issue of February 25th, that "when a radial bearing having a filling slot ie subjected to end thrust the balls are pinched at the slot, resulting in rapid wear to both balls and races," is true only of bearings in which the balls come in physical contact with the inner end of the filling slot. In the best bearings made to-day with filling slots, these slots are shallower than the ball paths, so that the balls must be sprung in under a greater pressure than they can possibly receive in service. Once in, they never again touch the slot, which virtually no longer exists. In such bearings the ability to endure end thrusts is roughly in proportion to the number of balls provided the requisite standard of accuracy is maintained.

New York City. J. B. BRETZ.

THE VALUE OF ACETYLENE AS FUEL.

Editor THE AUTOMOBILE:

[1,787.]—I read with a good deal of interest the discussion in "Letter No. 1763" in relation to the use of acetylene as a fuel in automobile motors, and it was my privilege some years ago to see a vehicle of this sort, built by some people in a northern New England State. This car was provided by a carbide feed generator.

At the time I gave the matter considerable thought, reaching the conclusion that nothing could come of it commercially. The cost would be excessive from the point of view of gasoline, since it is approximately possible to realize a horsepower using 1 pint of gasoline. This would cost about 1.9 cents. Now, even assuming that acetylene is 3.28 times more powerful than gasoline, it is also true that the cost of the neceesary 6 cu. ft. of gas would require the use of 1½ pounds of carbide at a cost of 15 cents.

If the average automobile is provided with a tank for gasoline that will hold 10 gallons, the fuel in the tank would weigh about 120 pounds, which represente the amount of carbide that could be carried without increasing weight. Then there is the water to use in dissolving the carbide, so that double the above weight would have to be coneidered as the least figure. Without going into further detail, it is plain to be seen that acetylene is not so very attractive at the present time. Nor is any account taken of the troublee which will follow the uee of a carbide generator on a large ecale. It will be remembered that carbide generators as used in lighting give about all the trouble that can well be tolerated due to the lime formation as a residue. HAROLD H. BROWN.

Boston, Mass.

HOW TO KEEP A WHEEL ON AN AXLE.

Editor THE AUTOMOBILE:

[1,788.]—In "Letter 1755," R. R. Kelsey mentions trouble in keeping the rear wheel keyed tight on the driving axle. This can be accomplished in the manner as shown in Figs. 1 and 2. Fig. 3 represents the present conditions under which the key will not hold.

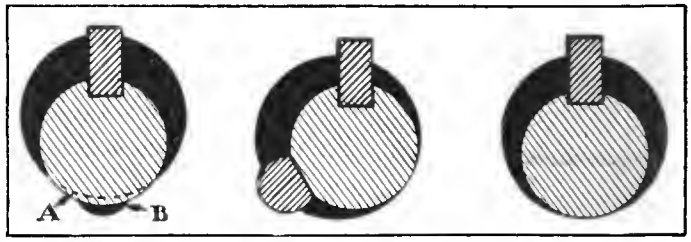


Fig. 1. Fig. 2. Fig. 3.

Fig. 1 represents the first method. With a half-inch round file make groove at A, opposite keyway, clear through hub. Then file off the portions at B with a half-round file until the shaft bears on hub for one-quarter inch width each side of groove A. Groove A must be not less than thres-eighths inch wide after the work is done. This groove is just as important as the bearing surface each side of it. The keyway in the shaft should be planed or milled to a better condition, and the keyway in the hub can be filed to match. The only objection to it is that, theoretically, it throws the hub "off the center" a little more than method number two.

For the eecond method, take a piece of iron of the same size of shaft and wedge it into the hub and drill a one-half inch hole half in the hub and half in the iron, one-third, 120 degrees around from the keyway, clear through the hub. This gives a half-round keyway in which a piece of steel is easily fitted to make a raised part in the hub, which gives us a three-point bearing.

When inspecting the machinery of the car, hit this key with a hammer, and if it ehows signs of iooeening up, take it out and put a thin piece of tin under for a shim.

Fulton, N. Y. C. V. ARMSTRONG.

LIKES THE HIDDEN TUBE IDEA.

Editor THE AUTOMOBILE:

[1,789.]—I have just noticed in your "Letters Interesting and Instructive" the suggestion by F. W. Ferguson (1,759) in regard to elimination of the flexible tube, connecting horn and bulb, and mentioning internal piping arrangement. I entirely agree with Mr. Ferguson, having broken two tubes myself, and know that they are the bugbear of cleaners and wipers, besides destroying, by a homely curved line, the sweeping horizontal lines of beauty of the body.

So I have invented a simple system of concealed piping which a well-known manufacturer has taken up and will use on all 1910 models—possibly on some of the 1909 cars as well. Mr. Ferguson certainly has the right idea, and I am surprieed that the matter has not been taken up before.

St. Louis, Mo. JOHN GULLY COLE.

Wright's Pupils Make Rapid Progress

King Alfonso of Spain Congratulates Wilbur Wright.

PARIS, March 4.—Minister of Public Works Barthou is such a great admirer of Wilbur Wright that on a recent visit to the district of Pau he rushed out to the aerodrome at Long-Pont and requested a second journey in the flyer. There was only half an hour to spare before the train left for Paris, but it was not many minutes before the machine was made ready and off with the minister and pilot aboard. For ten minutes Wilbur Wright showed his skill as a flyer by describing circles, soaring up and sweeping down, then passing over the heads of the spectators sufficiently high to clear them, but sufficiently low for the Minister to shout down a message. When M. Barthou had rushed for his train, his private secretary was initiated to the joys of a flight.

Two of the Wright pupils, Comte de Lambert and Paul Tissandier, are now efficient in the handling of the flying machine, and although they have not yet been aloft alone, have made several journeys of 20 minutes' duration without the intervention of the teacher. The training of the third pupil, Captain Lucas Girardville, will commence immediately, and it is expected that by the end of March three men will be fully capable of driving the machines. King Alfonso, of Spain, was a recent visitor at Pau, and evinced much interest in the flights.

DATES ARRANGED FOR AERONAUTICAL SALON.

PARIS, March 3.—Paris will have an aeronautical salon in the Grand Palais next Fall, probably from October 2 to 17. Aeroplane constructors, dirigible-balloon builders and automobile constructors interested in the manufacture of light-weight motors have formed a union which will take care of the exhibition. An interview has been had with the Under Secretary of State responsible for the palace in the Champs-Elysees, with the result that assurance has been given that the hall will be placed at the disposition of the flying-machine men. Although no attempt will be made to hold an elaborate show, and heating and light expenses will be cut out altogether, the number of those forming the union is sufficiently high to assure a successful event. Apart from those directly interested in the construction of flying machines, the following automobile firms are actively interested in the movement: Renault, Fiat, Bayard-Clement, Esnault-Pelterie, Gobron, Darracq; two tire firms, Michelin and Continental. The show cannot be regarded as other than a rival to the annual salon held by the Automobile Club of France. An attempt was made last year to put on foot a separate aeronautical show, but the French club stepped in and arranged for its incorporation in the commercial vehicle section, thus keeping all shows in its own hands. With an independent show for flying machines, and most of the big French automobile firms refusing to have anything to do with the 1909 salon, the task of the national club is not an easy one.

GERMAN AERONAUTICAL NEWS.

BERLIN, March 1.—A new German airship is being built by Dr. Wagner, of the Stettin "Vulcan" Wharf, in connection with the chief engineer of the Kiel Howaldto Wharf, which is to be a combination of the rigid and non-rigid systems without embodying any of their drawbacks. Neither wood nor aluminum will be used, but layers of papierolyn instead, alternating with various fabrics, such as batiste, linen, and unbleached silk, muceous, and steel wires. This will all be welded together and the airship built of the finished material, which is said to be much more durable than either steel or aluminum. Steps have been taken to finance the new concern and acquire the somewhat complicated plant for the preparation of the material. A million marks would be necessary, this including two airships as well, of which the first is designed in a size of 9,000 cubic metres, capable of covering about 65 kilometers in the hour, the shape somewhat resembling a Zeppelin.

Orville and Wilbur Wright have contracted to appear in Berlin in the fall to give an exhibition of their aeroplane. After the various ill-successes of Zipfel in the German capital with his Voisin machine, huge interest is being aroused by the fact that the Wrights' visit is definitely settled.

The project of a German autodrome will not take shape until next year, as the newly founded and most influential company to finance such has deemed it best to wait until the industry has quite thrown off the effects of the depression it has been passing through. Prince Henry of Prussia was present when this decision was arrived at.

SANTOS-DUMONT'S FEATHERWEIGHT FLYER.

PARIS, March 4.—With the return of the fine weather Santos-Dumont's diminutive flyer has again been brought forth for daily exercise. The machine, which holds the record for lightness and smallness, has been modified during the winter, and is now fitted with a two-cylinder, opposed air-cooled engine built by Dutheil-Chalmers. The power plant is above the main bearing surface, and in the slight angle formed by the two wings. The wooden, two-bladed propeller is mounted directly on the engine shaft without the use of a reducing gear. Below the wings is the driver's seat, composed of a piece of canvas stretched from two of the frame members and only five or six inches from the ground. All complete the aeroplane only weighs 330 pounds.

Santos-Dumont's New Diminutive 330-Pound Aeroplane.

AEROPLANE RACES FOR CHATEAULAND IN AUGUST

PARIS, March 3.—American automobilists contemplating a tour through Europe this summer can fix on two districts to visit if they are interested in aeroplane flights. The plains around the old city of Reims will be alive with the hum of mechanical birds at the end of August, and Chateauland will have artificial flyers during the month of September. Both districts are excellent for touring purposes, and will doubtless retain many a car and its occupants from distant parts.

The Reims programme is at present the most complete, and appears likely to be the most attractive. Starting on Sunday, August 22, and continuing until Sunday, August 29, there will be five distinct flying events, comprising an endurance test, a 30-kilometer speed test, a short-distance speed test, a high-flying test, and a race for passenger-carrying aeroplanes. In addition it has been decided that the Gordon Bennett Aeroplane Trophy, to be competed for by national teams of three, shall be included in the Reims programme. There will probably be a French elimination race on Monday, August 23, to pick out the three national champions, and the final race for the Cup on the following Sunday.

The important feature of this event is that all the items on the programme are within the capabilities of present-day aeronauts, and all prizes should be won. Unlike the Monaco meeting, and many of the private races announced for the coming season, there is no special element of danger in the Reims events, and no attempt to set the flyers an impossible task. Even the Gordon Bennett race only requires a minimum of 30-kilometers on a closed circuit, a task which at least thirty machines should be capable of accomplishing before the month of August.

Apart from the Gordon Bennett trophy and money prize accompanying it, the district has raised the sum of $40,000 to be devoted to the aeronautical week. The situation is ideal, the plain being at the very doors of Reims, within 90 miles of Paris, and easily reached from England, Switzerland, Belgium and Germany.

The main feature of the Chateauland aeronautical week will doubtless be the holding of the Aero Club of France Grand Prix for aeroplanes, an event which must be competed on a closed circuit, the minimum distance to be about 30 kilometers. The sum of $20,000 is being raised toward a prize list, this amount to be spread over several events for flying machines. The details of the programme have not yet been drawn up, nor has the exact date been fixed, but it is probable that the week chosen will be early in September.

SILVER DART FLIES EIGHT MILES.

BADDECK, NOVA SCOTIA, March 8.—Douglass McCurdy, in the big aeroplane, *Silver Dart*, by flying eight miles in eleven minutes and fifteen seconds to-day, established a new record in the work of the Aerial Experiment Association, which is conducting a series of flights here under the direction of Dr. Alexander Graham Bell, and doubling the length of its best previous flight.

After four preliminary flights, in which it was seen that the 50-horsepower motor was working splendidly, Mr. McCurdy started from the laboratory and droned over to Stoney Island and back, passing over Baddeck Harbor both times.

LABORATORY FOR AERO EXPERIMENTS.

PARIS, March 3.—The Aero Club of France wants a laboratory for aeronautical experiments, and proposes that the sum of $40,000 shall be devoted to this purpose. The club is prepared to vote a substantial subvention toward the work, and looks for the remainder of the amount in the form of a Government subvention and private subscriptions. At the present moment the Government has the sum of $20,000 to dispose of toward the encouragement of flying, and it is believed that some of this can be obtained for the laboratory, which will be established in or near Paris, and will be the first of its kind.

THE AUTOMOBILE CALENDAR

AMERICAN.

March 11-13.....Milwaukee, Wis., Hippodrome, First Annual Show of Milwaukee, Automobile Club.
March 13-20.....Minneapolis, Minn., National Guard Armory, Second Annual Show, Minneapolis Automobile Show Association. F. E. Murphy, Secretary.
March 15-20.....Rochester, N. Y., Convention Hall, Annual Show, Rochester Automobile Dealers' Association. Chas. J. Moran, Exhibition Manager.
March 22-27.....Toledo, O., Coliseum, Annual Automobile Show, Toledo Automobile Dealers' Association.
March 27-Apr. 3..Pittsburg, Duquesne Garden, Automobile Show, Pittsburg Automobile Dealers' Association.

Races, Hill-climbs, Etc.

March 23-26.....Daytona, Fla., Seventh Annual Florida Beach Races, Florida East Coast Automobile Association. New York Representative, W. J. Morgan, Thoroughfare Building.
March 24-27.....Syracuse, N. Y., State Armory, Automobile Show, Syracuse Automobile Dealers' Association.
April 5-10.....New York City, Carnival Week, New York Automobile Trade Association.
April 10.....New York City, Fort George Hill, Second Semi-Annual Hill Climb of New York Automobile Trade Association.
April 27-30.....Detroit, Mich., Four-Day Endurance Run, Detroit Automobile Dealers' Association.
May 3-6.....Harrisburg, Pa., Third Annual Endurance Run, 700 Miles, Washington, Baltimore, Scranton, Motor Club of Harrisburg.
May 18-19.....Norristown, Pa., Second Annual Endurance Run, Norristown Automobile Club, to Hagerstown, Md.
May 22.....Hartford, Conn., 200-Mile Endurance Run, Hartford Automobile Club.
June 1.....Start from New York, New York to Seattle Race, M. Robt. Guggenheim Trophy, to Alaska-Yukon-Pacific Exposition.
June 11-12.....New York City, Two-Day Mountain Tour and Reliability Contest to Catskill, N. Y., and Return, New York Automobile Trade Association.
June 21-26.....Binghamton, N. Y., Fourth Annual Endurance Run, Binghamton Automobile Club, Albany, Boston, Hartford, Newburgh.

FOREIGN.

Races, Hill-climbs, Etc.

March 31-Apr. 14.Monaco, Italy, Annual Motor Boat Regatta and Championships.
May 2.....Sicily, Targa Florio, Automobile Club of Italy.
May 26.....Russia, Moscow—St. Petersburg Race.
June 10-18.....Germany, Prince Henry Cup Competition.
June 14-19.....Scotland, Scottish Reliability Trials.
June 20.....France, Boulogne-sur-Mer Course, French Voiturette Race, auspices of "L'Auto."
July 13-17.....Belgium, Ostead Automobile Race Week.
August 22-29.....France, Reims, Aeroplane Races and Grand Prix, Aero Club of France.
Sept. 5.....France, Mont Venteoux Hill Climb.
Sept. 11-19.....Italy, Bologne, Florio Cup Race, Automobile Club Bologne.
Sept. 19.....Austria, Semmering Hill Climb.

CONNECTICUT LEGISLATORS ARGUING OVER AUTO LAW

HARTFORD CONN., March 8.—That there is much opposition to the present motor car law is evident, and that it is due mainly to the indiscretion of a small thoughtless element, that never heed the fellow who walks or drives in rural sections is also a fact. Hearings were assigned last week for the discussion of the bills submitted to the present Legislature, some of which would put a decided restriction on the sport. Some of the bills would tend to improve matters. The hearings were before the committee on roads, rivers and bridges, in the hall of the House. Some of the remarks passed were decidedly antagonistic. One bill provides for the fitness of a person applying for a license, which shall be determined by the Secretary of State, and adopts substantially a part of the New Jersey law, which would eliminate the present "reciprocity" feature of the Nutmeg State law and compel every non-resident to register in this commonwealth, reduces the speed limit to 20 miles an hour outside the city limits, 12 miles within and compels drivers to bring their cars to a stop when approaching trolley cars not in motion.

The present law was thought to be a model one, and some so regard it at the present time. In the hands of sensible people it was a good law, but there is the road hog and the speed maniac and it is against them that the public needs some sort of protection. The present law is a good one, but some safeguards must be thrown about it.

Some of the speakers favored a stricter examination of the qualifications of chauffeurs, and ex-Representative Birdseye, of Farmington, an automobilist, spoke strongly in favor of the present law, and referred to a series of resolutions adopted by the Farmington grange, the gist of which were as follows: To secure uniform legislation throughout New England; to provide an effective means for enforcing the law; to tax motorists according to horsepower; to have new markers each year; no colors to be duplicated within four years; to have all licenses expire December 31 of each year; speed limit to be placed at not over 25 miles an hour and 8 miles an hour around corners.

A. C. Judd, proprietor of the Hotel Elton, at Waterbury, spoke for the hotelkeepers, and stated that his establishment, which had been erected at a cost of $400,000, would not pay expenses if it was deprived of the patronage of automobilists.

Walter S. Schutz, attorney for the Automobile Club of Hartford, said it seemed to be practically agreed that 75 to 85 per cent. of motorists are all right and proper. There are from 15 to 25 per cent. that have to be punished. He referred to that feature of the present law which provides that all convictions shall be reported to the Secretary of State. The records show that not one-third of such convictions have been reported and that the fault is with the authorities themselves. Autoists desire to see the man guilty of wrongdoing summarily punished. He suggested that some department of the State be given the enforcement of the law, and that the question of the revocation of licenses be lived up to. Make the law more specific, if necessary, by giving the Secretary of State the right to revoke licenses upon complaint of any violation without conviction.

It is a common impression in local circles that something will happen to the present law. Those who make the laws are well aware of the fact that the innocent always suffer for the guilty, but, nevertheless, the harm has been done and some one must pay the fiddler. Many members of the Legislature own and operate automobiles. Just how soon the matter will be put before the assembly for final action is a question.

COLUMBUS WANTS TO COLLECT LICENSE FEES.

COLUMBUS, O., March 8.—Automobile owners of Columbus are up in arms over the decision rendered by Judge Dillon, of the Common Pleas Court of Franklin County, holding that a municipality has a right to collect the automobile license, provided for in the vehicle license ordinance. When an attempt was made to enforce this, William M. Frisbie, a member of the Columbus Automobile Club, brought a test suit on the ground that the city ordinance conflicted with the State law. The latter provides for registration and identification of motors with a fee of from $3 to $5. The club secured a restraining order and the city auditor refused to accept any fees until the case was decided. The city solicitor took the case up with the result that the law was sustained.

At a meeting of the Columbus Automobile Club steps were taken to carry the case to a higher tribunal. One of the principal objections is the fact that the money sought to be raised by the license does not go for the improvement of the streets. The money received from the State department, on the other hand, save that used in paying the expenses of the office, goes to the good roads fund.

MARYLAND'S GOVERNOR FAVORS AUTO TAX.

BALTIMORE, March 8.—Governor Crothers is determined to have the automobilists of this State pay full taxes as set forth in the Swann automobile bill that they may pay their share of the cost, according to his figuring, of building and maintenance of good roads in the State. He declares that neither he nor the Auto Commissioner are anxious to do anything unconstitutional or to make motoring in this State a burden to owners of cars. Neither does he agree with the owners that they are being worked for oppressive taxation by those handling the bill. He points out that the rule applies to street railway companies which pay a license tax in addition to the general levy on their property.

MICHIGANDERS OPPOSE HORSEPOWER TAX

GRAND RAPIDS, Mich., March 8.—The Michigan State Automobile Association is making plans to oppose Highway Commissioner Earle's efforts to get an additional tax put upon automobiles. The latter's plans, as they mature, seem to be to have a bill introduced into the present session of the Legislature taxing automobiles owned and operated in the State ten cents per year for each horsepower, making the tax on a 60-horsepower car, for instance, $6. This would be in addition to the annual registration fee of $1, which autoists now have to pay, besides the personal property tax on the machine. The commissioner's idea is that automobiles do more harm than other vehicles to the roads and should be made to pay accordingly.

This, however, does not accord with the view of the autoists, and J. R. Jackson, president of the association, says the law will be opposed. "While the associated clubs through the State," says he, "are in favor of road improvements, and are willing to do even more than their share in bringing about improved conditions, such a measure as this would be gross injustice."

The dealers are also taking a hand in opposing it, claiming that it is class legislation, and that if an additional tax is needed for road improvements it should be a general tax on all vehicles, and not a fine on automobile owners for having machines.

NO AMENDMENTS TO OHIO LAW THIS SESSION.

COLUMBUS, O., March 8.—Several bills pending in the Legislature provide for amendments to the State law for the registration, identification and regulation of motor cars. None of the bills have been enacted into a law and some carry unreasonable features. One of the amendments provides for the painting of the number on a glass background to be shown by light during the night. Because of the fact that the Legislature will soon adjourn, it is not believed any material change will be made in the law.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

SUCCESS IS KNOWN BY ITS COMPANY.

When the automobile was projected into the keeping of man, out of the fertile brain of genius, it presented a moot question, nor could fortune's predictor say that success would deign to permanently occupy a seat in the tonneau. At Boston, seven years ago, when the virgin New England show, as a débutante, rent the placid atmosphere with its siren call, it challenged all the chariots of the world to come and contend for success, and the spectacle was inspiring.

The refined of the "Hub" ventured forth and gathered in the arena to view with critical eye what was, to be sure, a somewhat meager exhibition of automobiles. But the sagacity, which is at the bottom of what is known as New England conservatism, pierced the future, and the show returned, a second time, after a twelvemonth, in better form.

From that day to this the Automobile Show has been an "event," and for seven years New England's representative people came in dignified, but increasing numbers, to witness the advances made, and to support the industry by substantial patronage. Each succeeding year has been a little better than the last, and that strange jewel, consistency, robbed dire prediction of its potency, while the automobile found a fitting response in the hearts of what is said to be the most conservative, nay, critical, audience on the North American continent.

Naturally, the commercial phase of the situation is as an echo of this New England approval of the automobile, and sales were made on a gradually increasing basis each succeeding year, until to-day it assuredly would require an upheaval of the imagination to tender justice to the situation. Boston is now a center of activity in the automobile zone, after which a deluge of excellent business is sure to follow.

* * *

INSTABILITY ACCENTUATED BY SKIDDING.

As the microscope unveils the microbe which may be at the root of a disorder, so does "skidding" disclose acute instability to an autoist who persists in driving around curves at high speed. The very condition of instability which is rendered manifest by skidding on a curve is ever present in cars directly they are guided out of the straight course, and designers as well as drivers must bow to the natural law which enables centrifugal force to overcome traction.

Of two prime sources of trouble, ill devised compensating gearsets (differential gears) should be looked upon as possibly the more serious. If the compensating gears fail to work one of the rear wheels must slip, and it is a property of traction to forfeit its potency instantly slipping begins. This point is adequately illustrated in brakes which fail to perform the braking function if excess pressure is applied enough to cause the wheels to slip. Obviously, the same phenomenon will follow if the differential gear sticks sufficiently to defeat compensation.

The second fault will be present if one of the steering road wheels must slip on a curve, which condition will surely follow if the tie-rod arms are not set properly. Unfortunately, it is impossible to locate these arms in such a way as to render their action universal, but they can be set for the radius of curvity likely to obtain in actual practice, taking into account the manner in which roads are built, with an eye to the free space at the intersections of streets, such as would invite speeding on a curve.

Beyond these fundamental considerations there is nothing to interfere with safety in driving cars around curves, excepting careless workmanship, inferior materials and "feather-weight" designing, unless it is that autoists want to play "bully bender," as boys are wont to do on a handy mill pond, but thinly veiled 'neath meager ice. There is no room in the automobile industry for men who persist in supporting any of these "pastimes," and one of the reasons is that innocent spectators must be protected from the gangrene infested.

* * *

TAXICAB PROGRESS REALLY WONDERFUL.

A study of the taxicab situation will convince anyone that the motor-driven cab is here to stay and must ultimately drive out the horse-driven rig. These convenient little vehicles may make money for the company operating them, but, regardless of this, the public have taken to them and will have nothing else. The larger cities are rapidly increasing their complement of cabs and it is a noteworthy fact that, no matter how small the city, no taxicab service, once started, has been withdrawn. An article elsewhere in this issue gives detailed figures for the number of cabs in use in large cities.

TROUBLE OVER CONTEST CONTROL UNLESS SIGNS FAIL

THERE is trouble brewing in the matter of control and sanction of automobile contests of all kinds, but particularly in the two more prominent branches, as races, tours or reliability runs. There was a time when the national governing body had the last word; what it said went, and the promoters of contests meekly obeyed. Now all that has been changed by ill-advised and domineering methods, which have antagonized even the friends of the "powers that be." From meek obeyance of orders to open defiance is a far cry, yet that is the situation to-day. This spirit of revolt is not sectional, but general, and must inevitably result in some radical change. What this will be is hard to predict at this time, but when a club can plan a complete run, down to the last detail, and then write to the governing body and say (as did the Contest Committee of the Harrisburg Motor Club recently), "upon receipt of the proper official notification we are quite willing to pay to your committee the sum of twenty-five dollars" (the sanction fee as quoted), it is self-evident that trouble is brewing, or, to descend to the language of the street, that there will soon be "something doing."

The chances are that very soon there will be a revolt, and the club mentioned above will doubtless be found in the forefront at that time. The attitude of manufacturers toward the present control is well known and will need no comment here. It is to be hoped, however, in this connection, that the new M. C. A. formed from the manufacturers and importers, will step in and assume control before the situation becomes chaotic and impossible. This is a step that must come as inevitably as to-morrow, and the sooner it comes and thus relieves the present strained situation. in which clubs are "quite willing" to pay for sanctions, the better it will be for all concerned.

A. L. A. M. MEETS AND ELECTS A NEW MEMBER

NEW YORK CITY, March 8.—At the important meeting of the board of managers of the A. L. A. M., held last Thursday, nearly every firm was represented, 26 of the 31 members being present. The report of the show committee made by Col. George Pope, its chairman, was enthusiastically received. The show was the most successful ever held, both as to receipts and business done by exhibitors. Over $40,000 will be rebated to vehicle exhibitors and members of the Motor and Accessory Manufacturers' and Motorcycle Manufacturers' Associations. The rebate not only leaves in the hands of the show committee a large working capital for the next show, but is the highest rate of refund ever made to the exhibitors of a national automobile show, being an increase of nearly 40 per cent. over the rate of rebate of the seventh automobile show at Madison Square Garden in 1908, and of nearly 100 per cent. over the rebate of the same show in 1907. A vote of thanks was accorded the show committee for their work. The same committee (Col. George Pope, chairman; Charles Clifton and E. P. Chalfant, with M. L. Downs as secretary) was appointed to conduct the tenth automobile show at Madison Square Garden, which will be held in January, 1910.

A new member was elected, and in this the city of Detroit scores once more. The latest addition to the licensed family is the Hudson Motor Car Company, of Detroit, Mich., named after its president, J. L. Hudson, one of Detroit's largest merchants. This is a new company, organized for the purpose of manufacturing a four-cylinder car. to be built in large quantities.

THERY, FRENCH RACING DRIVER, DEAD.

PARIS, March 9.—Francois Leon Thery, famous as a racing driver, died at his home here last night. He was born in Paris, April 16, 1879. After a fairly prosperous early career, in which he won many minor contests, in 1903 he entered the employ of Richard Brasier, with whose cars he had unusual success. In that year he won the French elimination tests and many other races. The next year, 1904, in the Gordon Bennett race over the Taunus course, starting from fifth position in an 80-horsepower Brasier, he surprised everybody by easily beating Jenatsky in a Mercedes. The time, 5:50:05, was at the rate of 53 miles per hour, then considered wonderful.

The following year, on July 5, over the Auvergne circuit, he repeated this performance in slower time. This double victory marked the height of his racing supremacy, for although always a big factor, he later failed to capture any of the larger events. He continued with the Richard Brasier firm up to his death.

GRAND PRIX PROMOTORS GET OFF EASY.

PARIS, March 3.—The Automobile Club of France has got out of its Grand Prix with a loss of $800 only. Natives whose land had been rented for grandstands, etc., protested at the abandonment of the race, and certain villages spoke of suing for damages. The matter was settled, however, by the payment of the sum of $800 to the organizing committee to be distributed as an indemnity to those persons who had actually entered into an agreement to rent their land. Medals will be granted to all commissaires who acted at the last Grand Prix races, and, this accomplished, the Racing Board has practically ceased business for twelve months.

FAMOUS THOMAS IS SEATTLE PATHFINDER.

NEW YORK, CITY, March 10.—To add to the laurels which it won in the race around the world, from New York to Paris, the famous Thomas car has now been slated for another strenuous trip, that of the pathfinder from Chicago to Seattle, of the race from this city to the Alaska-Yukon-Pacific Exposition. This has been arranged between the managers of that contest, and the E. R. Thomas Motor Company, of Buffalo, but as yet the car which will inspect the roads from this city to Chicago, if one is thought necessary, has not as yet been chosen.

The Thomas will leave this city on March 15, to run to the Windy City, where John Kane Mills will meet it and go over proposed routes from that point to the Pacific coast. It is expected that it will take at least a month to make the preliminary surveys, and should the mud of Nebraska be forbidding, a southern course, through St. Louis and Denver, may be selected.

KNOX DECLARED WINNER OF SWEEPSTAKES.

NEW YORK CITY, March 8.—The announcement was made recently that William K. Vanderbilt, Jr., referee of the Motor Parkway sweepstake races held on October 10, on the occasion of the formal opening of the Long Island Motor Parkway, has disqualified the Sharp Arrow car, which won in the Garden City class. This disqualification gives the first place and the prize to the Knox Model O, which was driven by William Bourque.

The races were open to stock cars, of which ten had been built previous to the race. It was upon this ground that the referee disqualified the Sharp Arrow, it having been proven to him that the competing car was the only one of its type that had been built. Consequently, the $1,000 will go to Springfield.

What the Clubs are Doing These Days

SAVANNAH CLUB ELECTS OFFICERS.

SAVANNAH, GA., March 8.—At the annual meeting of the Savannah Automobile Club held last week the officers who so successfully guided the organization through the past year and superintended to a great degree the Grand Prize race, were unanimously re-elected. They are: Frank C. Battey, president; J. J. Rauers, vice-president, and A. W. Solomon, secretary and treasurer. The board of governors was chosen as follows: F. C. Battey, J. J. Rauers, A. W. Solomon, George W. Tiedeman, George J. Baldwin, Harvey Granger, F. M. Oliver, C. G. Bell, D. G. Rosenheim, Wright Hunter and A. B. Moore.

President Battey announced the appointment of the following executive committee: Chairman, Harvey Granger; vice-chairman, W. W. Williamson; W. B. Stillwell, George W. Tiedeman, A. W. Solomon, Albert Wylly, George J. Baldwin, Leopold Adler, J. A. G. Carson, F. C. Battey, T. J. Charlton, F. M. Oliver, A. B. Moore, J. J. Rauers, J. M. Dixon, W. B. Stephens, R. M. Hull, Abe S. Guckenheimer and S. E. Theus. Governor Hoke Smith, Governor-elect Joseph M. Brown and Robert Lee Morrell were elected as honorary members.

The splendid success which has attended each of the three races held here, especially the Grand Prize, leads the club to believe that it can get that great event for another time, and has decided to ask for it for next Fall. Pictures of the last race will be sent to every automobile club in this country. Plans for the annual country run, which is held in April, are about to be started. It is not known as yet where the course will be nor when it will be held, these points having yet to be decided, the many good roads giving ample room for choice.

ROCHESTER CLUB PLANS NEW ENGLAND TOUR.

ROCHESTER, N. Y., March 8.—At the recent meeting of the board of directors of the Rochester Automobile Club it leaked out that a long tour is planned for the coming Summer by Secretary Van Tuyle. This event, which is not so very far off, in reality, will include some of the most historic and picturesque places in the East, and will not be competitive in its nature. More than a score of the members immediately volunteered to participate, so that the success of the run is assured.

The purpose of the meeting was for the nomination of officers for the coming year. It was necessary to persuade President Henry G. Strong to run again, but after that was settled there was no difficulty in choosing the others. The rest of the nominees are: Vice-president, William C. Barry, Jr.; treasurer, Rudolph Schmidt; secretary, Bert Van Tuyle. Board of governors—George C. Gordon, F. E. Mason, John E. Morey, A. F. Crittenden, W. S. Hibbard, H. S. Woodworth and John S. Bingeman.

Other minor matters to be disposed of were the adoption of a club pin and the election of George C. Gordon as chairman of the banquet committee. This will be held March 29, in conjunction with the annual meeting. This happy date selection also catches the annual meeting here of the New York State Automobile Association, delegates to which will be entertained at dinner.

MARSHFIELD, WIS., TO HAVE AUTO CLUB.

MARSHFIELD, WIS., March 8.—An automobile club is to be formed in this city as the result of agitation by the Milwaukee Automobile Club, which is leading the fight of the Wisconsin State Automobile Association for better highways in the northern part of the State. All the wealthy lumbermen located here are owners of autos, and as the new club will be largely composed of them, wide influence will be exerted.

QUAKER CITY CLUB REINSTATES PREMIER.

PHILADELPHIA, March 8.—After a hotly contested fight to have its disqualification withdrawn, the Premier touring car which finished the New Year's Day run of the Quaker City Motor Club to Wilkes-Barre and return, with the only perfect mechanical score, but which was disqualified for having gone part of the way up Giants' Despair Mountain without its full complement of passengers, has been reinstated by the club, but with a penalty of 270 points on its time score, placing it thirteenth in the order of those which finished.

This was decided upon at a meeting of the new contest committee of the club recently. The record of the meeting says: "From the records of the observer in said Premier car, and from the official records of the Quaker City Motor Club, it appears that said car passed the checking station at Hazelton 7½ minutes ahead of schedule time and 25½ minutes ahead at the following checking stations: Hamburg, Reading, Pottstown, Norristown and at the finish." The penalty placed against the car was the total, 270 points, one point for every minute ahead of time.

President L. D. Berger has appointed the following to the contest committee, with two additional names still to be announced: Ferd M. Johnson, chairman; Fred C. Dunlap, R. E. Ross, G. Hilton Gantert, W. J. Donnelly, W. West Randall and F. K. Worley.

NORRISTOWN CLUB WILL RUN TO HAGERSTOWN.

NORRISTOWN, PA., March 8.—The contest committee of the Norristown Automobile Club has finally decided upon Hagerstown, Md., as the outer mark for its two-day endurance run which is scheduled for May 18-19. The intermediate controls have not yet been decided upon. The round trip will approximate 300 miles. A pathfinding expedition consisting of three cars—a Matheson, a Crawford and an Overland—will take a trip over the route as soon as the roads will permit.

At the annual election last Friday evening the following officers were chosen to serve during the next twelvemonth: President, John H. Rex; vice-president, Isaac A. Smith; treasurer, L. E. Taubel; secretary, William B. Hart. Board of directors—Lewis E. Taubel, Harry A. Wilson and William B. Hart, for three-year term; Samuel Roberts, John E. Mountain and Frederick M. Jaquith, for two-year term; Robert A. Jackson, A. H. Root and H. C. Carney, for one-year term.

COLUMBUS CLUB HAS REMARKABLE GROWTH.

COLUMBUS, O., March 8.—The Columbus Automobile Club, which recently opened elaborate clubrooms in the Northern Hotel, now has more than 300 members and is quite prosperous. Since the opening, about three weeks ago, the clubrooms have been, and will be kept open permanently, with the officers in charge. The regular meeting is on the first Monday evening of every month, with occasional club evenings. The following are the officers: Max Morehouse, president; Perrin B. Monypeny, first vice-president; George P. Stevenson, second vice-president; Herman Hoster, treasurer; Normal O. Aeby, secretary.

GRAND RAPIDS CLUB STILL AFTER A HOME.

GRAND RAPIDS, MICH., March 8.—The local club is still considering the project of building a new clubhouse, but the organization seems to be about equally divided as to whether the new building should be erected in the city or whether a suburban location should be chosen. A vote on the question will probably be taken at the next meeting.

PENNSYLVANIANS OPPOSE GRIM BILL.

PHILADELPHIA, March 9.—At the annual meeting of the Automobile Club of Philadelphia, at the Racquet Club, last night, a call was sounded for co-operation in the effort to put the Grim bill through the Legislature, now in session, and to antagonize by every legitimate means the progress of legislation introduced by automobile baiters. The various reports were most enthusiastically received, especially that of W. O. Griffith, chairman of the Committee on Routes, Maps and Sign Posts, which showed upward of 1,200 posts erected, a road book printed and much other work. President Powell Evans' report showed a membership total of 708. The effort to locate and build a club house and garage evidenced early fruition of the plans of the committee in charge, headed by Dr. D. Braden Kyle.

The terms of four members of the Board of Governors having expired, three of them were re-elected and W. O. Griffith chosen in place of Isaac Starr. That body is now made up of Powell Evans, S. Boyer Davis, D. Braden Kyle, Henry P. Baily, Jacob J. Seeds, Stedman Bent and W. O. Griffith.

As an appreciation of the services of the last-named gentleman as chairman of the Routes, Maps and Sign Posts Committee he was presented with a handsome high-grade speedometer by the club.

DAVID WILL TACKLE ROAD GOLIATH ALONE.

PHILADELPHIA, March 8.—Manager William P. David, of the local Middleby agency, has been endeavoring to get some of his $1,250-or-under confrères to trot him a heat from this city to Pittsburg and return for a $500 wager, just to demonstrate the effectiveness of the air-cooled principle from the Middleby viewpoint. But after wearing the chip on his shoulder for over a week without landing a competitor he has taken down the money, which he had posted with the editor of the Philadelphia *Inquirer*, and will send his car over the route alone after making the necessary arrangements to have the test officially timed. The route going and returning will be as far as possible over the proposed Philadelphia-Pittsburg cross-State highway, which is now being discussed in the Legislature.

RESTRICTIVE CHANGES IN FRENCH PATENTS.

France for the French seems to be the main idea as embodied in the new French laws as they relate to "leters patent" such as may, in future, be taken out in that country. Under the new law, unless a patent is "worked" within a period of three years from the date of issue it will be void. But this French law is wider in its scope, in that it holds to the dictum that, "the patent courts will be invested with discretionary power to call upon the holder of a patent to show cause why he should not exercise his right in French territory, in an adequate degree." Under the new French law then, a foreign "patentee" is at the mercy of the court; with no more definite right than "the court allows."

MID-WINTER AUTO TRIP TO SAVANNAH, GA.

To some a tour in an automobile means a trip in delightful summer weather, over roads smooth and dry. To others it means a test of endurance, when roads are at their worst. It was under the latter conditions that C. A. and W. A. Warren and Dr. E. D. Loughran, of Kingston, N. Y., have just completed a journey from New York to Savannah in a Stoddard-Dayton Model K roadster. The route followed was via Philadelphia, Gettysburg, Winchester, Natural Bridge, Danville, Charlotte, Columbia, Augusta to Savannah.

HARTFORD SHOW MADE GOOD PROFITS.

HARTFORD, CONN., March 9.—The recent automobile show held in Foot Guard Armory will net the exhibitors a dividend of about 40 per cent., which will be passed upon at the Dealers' Association meeting next week.

BRINGS SUNNY SOUTH TO ZERO COUNTRY.

A quick change from mid-winter in Yellowstone Park, with the mercury forty degrees below zero, to the genial warmth of the slopes with which Southern California borders the Pacific, has been made by H. W. Childs, manager of the Yellowstone Park Association, in a trip with a party in a Franklin touring car, his experience emphasizing anew how wide climatic differences are set at naught by the use of the automobile. San Diego, Cal., was the objective point of the trip, the party thence working up the coast to San Francisco.

Mr. Childs states that the number of tourists will be greatly augmented by automobilists headed for the Alaska-Yukon-Pacific Exposition, and while there have been restrictions on the use of motor cars in Yellowstone Park, a change in their favor has been coming. An evidence of this is the recent replacing of one of the last of the old stage coaches by a Franklin touring car.

PEERLESS FACTORY ADDITION MOST FINISHED.

CLEVELAND, March 9.—The Peerless Motor Car Company, of this city, is rushing work upon the new office and factory buildings. For some time the Peerless people have been very badly cramped in both executive and factories quarters, and the new structures are expected to relieve the congestion. The factory building will be four stories in height, while the office structure will be half as high. Both will be built of brick, concrete and steel throughout, and will conform to the general plan of all the Peerless buildings.

The trade in general in this city is undergoing a steady boom—not the mushroom kind, but a healthy growth. The past week has seen one new agency come into the local field, while another general garage concern has opened up. J. F. Egensperger, formerly indentified with the Northern in this city, has accepted the agency for the Sterling, built in Elkhart, Ind., and demonstrators are expected this week. The Auto Sales Company, managed by John W. Rauch, has started business at 1121 Chestnut avenue.

NEW CHICAGO HOME FOR PACKARD.

CHICAGO, March 8.—Following the lead of the metropolitan agents of permanently locating in high-class buildings properly located among the right surroundings, the Chicago Motor Car Company, selling agents for the Packard, has leased for 99 years the northwest corner of Michigan avenue and Twenty-fourth street, which, together with the purchase of the property at 128-130 Twenty-fourth strect, will give a space for the new building of 60 by 200 feet. The existing buildings will be demolished and a four-story reinforced concrete structure will be erected, to be ready for occupancy by August 1, 1910.

Comedian James E. Rosen in His Overland Roadster.

Mr. Rosen is the famous little comedian who created the part of "Buster Brown," and is now playing in the "Newlyweds" as the baby. He purchased the car at the recent Cleveland Show, and will do extensive touring with it during the vacation season.

How the Chalmers-Detroit Big Shipment Looked When Unloaded.

What is claimed to be the largest single shipment of automobiles ever sent from Detroit to a single dealer, was that of 46 Chalmers-Detroit "30's" that went to H. E. Fredrickson, the Omaha, Neb., agent. The freight cars bearing this consignment left Detroit all together in one train. When they were unloaded at Omaha, they were lined up for the above picture.

Moon Company Arranges Lecture Course.—In order to give its employees a practical idea of automobile construction, instead of confining them to the knowledge of the certain parts which each makes, the Moon Motor Car Company is arranging a lecture course for their benefit exclusively. It is planned to give short talks after the luncheon hour, and a recent experimental lecture showed the amount of interest aroused. At night there will be frequent illustrated lectures, and throughout the course authorities in the automobile engineering field will be called upon. Stewart McDonald, general manager of the company and a member of the Society of Automobile Engineers, will take up more general topics of pertinent interest.

Auto Races on Tampa Track.—A series of automobile races, which will be held at frequent intervals during the year on the half-mile track at the Tampa Bay Hotel, was started by a meet on February 23, the time being slow because of the size and condition of the course. The feature of the day was a five-mile event for touring cars carrying four passengers, which was won by E. T. Bryan's Premier in 7:24, with P. Arguelles' six-cylinder Ford second and W. F. Ferman's Cadillac third. This car was the fastest of the trio, but was held up by dirty gasoline. A three-mile race for cars under 15 horsepower was won by C. B. Witt's Franklin, and one for cars of 22 horsepower or under at five miles was won by H. D. King's Buick.

Refrigerator, Lunch Case and Alcohol Cooker.—Most interesting of all is what may be called a close-coupled limousine in that the tonneau has but one seat to accommodate three. Behind this seat is a false back, to which access is had through doors opening from behind the car. This false back contains lockers the full height of the body, a refrigerator, lunch case with alcohol cooker, and storage space for six suit cases. On the roof, which is of the cabin-deck type, with portholes for ventilation, is a tank which provides water. This is probably one of the most interesting body undertakings that the Quinby Company, of Newark, N. J., ever devised.

Many Farmers at Omaha Show.—Earle J. Moon has recently returned to the factory of the Moon Motor Car Co. from the Omaha show, much impressed with the numbers of farmers interested. He said: "It made me realize what an important person the farmer has become. Only a short time ago these people looked upon automobiles as beyond their comprehension and were much against them, but it is different now, at least in Nebraska. Those at Omaha showed not only an interest but an accurate knowledge of machines and were well able to buy when they found what they wanted."

Close-couple Body with Double Rumble Seat.—Innovations in body designs are still to be seen in the haunts of the advanced designers, and autoists persist in wanting specialized products. There is now at the shops of the J. M. Quinby Company, Newark, N. J., a type of close-couple body with double rumble seats, which will gladden the heart of Owen Osborn, of Philadelphia, for whom it is being built. The double rumble will accommodate the chauffeur and the maid, nor will their confidences reach the ears of the occupants of the body proper. "It is a poor rule that does not work both ways."

Kisselkar Also Stars on Pacific Coast.—Later advices from the scene of the Pasadena-Altadena hill climb show that the performance of the Kisselkars was worthy of note. Three different models were entered, of 30, 40 and 60 horsepower, respectively. The thirty won the touring-car class for cars selling between $1,001 and $1,500; a forty finished second among the touring cars selling between $1,501 and $2,000; a forty roadster won the event for that type of machines selling between the same prices, and the sixty was second in both the $2,500 to $3,000 roadster class and in the free-for-all stock roadster class.

Alco Cars Make Dèbut in Los Angeles.—With W. P. Brooks in charge, a building on South Oliver St. will soon be animated with Alco cars, and the agency is expected to be a "live one" in view of the projected $3,000,000 appropriation, made by Los Angeles County, with which to build roads. The American Locomotive Automobile Company, of Providence, R. I., builder of the Alco, is imbued with the idea that California will absorb many an automobile in the near future and preparation is being made to enjoy some of the prosperity.

Winton Self-Starter Always Ready.—"Proof of the pudding is in the eating of it." A. A. Marshall, of Fitchburg, Mass., went to California, leaving his Winton "Six" on dead storage, and when he returned six weeks later, on Feb. 13, last, it was with no idea that the car would respond instantly to the self-starter, when he tried the trick. Mr. Marshall soon learned, however, that a Winton starter is not rendered "hors de combat" by six weeks of cold storage. The motor responded to the self-starter without ado.

Can't Keep a Good Firm Down.—Although it has suffered a severe loss by the fire which totally destroyed the main factory, the Automobile Supply Mfg. Co., of Brooklyn, N. Y., has been able to take care of the orders on contract at the other two plants on Taaffe place and Classon avenue. At the former plant 12,000 additional feet of floor space has been secured and a new plant fitted up. The president of the company, Louis Rubes, states that all present and future orders will be promptly attended to.

Superior Manganese Comes from Japan.—In dry cells manganese is used for a depolarizer and it is of the greatest importance to have the same not only pure, but in acceptable shape. Formerly the product used came from the land of the "Czar." The Rock Island Battery Company, of Cincinnati, recently placed a large order for Japanese manganese and the company reports that American business relations with the Japanese are excellent. The Japanese product is a little higher in price.

R. F. Hardy Company's Guarantee.—"Sta-Rite" spark plugs, which are well and favorably known to the trade, have proven to be so reliable in service that the company now proposes to offer users what amounts to a perpetual guarantee, in that the plugs will be kept in good repair free of charge for all time. At the works of the company in New York City, it is reported that the plugs returned, thus far, proved to be those which have seen four or five years' service.

Kissel Factory Working At Night.—The plant of the Kissel Motor Car Company, at Hartford, Wis., which was recently enlarged to treble its former size, is now working both day and night shifts on its estimated production of 1,200 cars per year. Increased work has been necessary especially upon the new-size cylinder models, the orders for which exceed the capacity of the plant in producing.

Owen Thomas Will Build New Factory.—Rapidly increasing demand, coupled with ill-adapted rentable buildings, urges the Owen Thomas Motor Car Company, of Janesville, Wis., to adapt the expedient of putting up its own factory. Orders in hand for cars, taking into account prospects, urges the company in undertaking the work of erecting a plant at once.

India Agency Wanted.—An American exporter is preparing to establish permanent show rooms for American goods in India. The plan will be conducted along strictly American lines, and only selected lines of machinery and automobiles will be displayed. Further particulars can be obtained by addressing 3075, Bureau of Manufacturers.

Reliable-Dayton Increases Capital.—The Reliable-Dayton Motor Car Company, Chicago, makers of carriage motor cars and delivery wagons, has increased its capital stock from $25,000 to $200,000, fully paid in. The company was incorporated under the laws of Illinois in 1907, in its third business year.

IN AND ABOUT THE AGENCIES.

Mitchell and Auburn, Wichita, Kan.—Advices from M. L. Arnold, of the United Motor Company of Wichita, Kan., State agent for the Mitchell and Auburn cars, announce that the report published in these columns on February 25 that Mr. Arnold would hereafter be connected with J. L. Sternberg & Company, at 119 East Second street, the agent for the Inter-State car, is incorrect. Mr. Arnold writes that neither he nor his company is in any way connected with J. L. Sternberg & Company and will continue to handle the Mitchell and Auburn at 115 to 119 East Second street, as in the past.

Oakland, Philadelphia.—The Oakland car, which was formerly represented in the Quaker City by the Bergdoll Motor Car Company, will henceforth be looked after by the Oxford Automobile Company, 238 North Broad street, which also handles the Brush and Grout output in Philadelphia and contiguous territory.

American Agency Wanted in Asia Minor.—The Bureau of Manufactures, Washington, D. C., will forward to a business man in Asia Minor any propositions which may be addressed to No. 3110, care of the Bureau. It is reported that there is a field in Asia Minor for automobiles.

Pierce Arrow and Oldsomobile, Austin, Tex.—The Houston Motor Car Company has opened a branch in Austin, in addition to its branch in San Antonio. The company will sell the Pierce Arrow and Oldsomobile.

Royal Tourist, Seattle, Wash.—The newly formed Royal Sales Company has secured the agency for the Royal in the Northwest and will push the sales in Tacoma, Portland, Seattle and other large coast cities.

Jackson and Ford, Morristown, N. J.—Seaman Brothers have been appointed sub-agents for the Essex Automobile Company, of Newark. They will represent the Jackson and Ford cars.

Moline, Davenport, Ia.—C. P. Peterson, of Davenport, has taken the agency for the Moline and will build a large garage. He will have charge of all sales made in the three cities.

White, Denver.—C. S. Newsom, who has been appointed agent for the White steamer in this city, will establish headquarters at Fifteenth street and Cleveland place.

Firestone, Baltimore.—The Firestone Tire & Rubber Company has placed a distributing agency with R. Milton Norris, 516-18 W. Baltimore street, Baltimore.

Reo, Wisconsin.—The Cumberland Auto Company, of Cumberland, has arranged to handle the Reo in six counties in the northern part of the State.

E-M-F and Studebaker, Savannah.—The Graham Automobile Company has taken the agency for the E-M-F 30 and Studebaker cars for this vicinity.

Regal, Youngstown, O.—L. P. Hoffmaster and C. A. Clifford have formed a partnership to handle the Regal car in the northern Ohio town.

Schacht, Montclair, N. J.—W. L. Mason has secured the agency for the Schacht, a high-wheeled auto, manufactured in Cincinnati.

Maxwell, Savannah.—The Maxwell-Briscoe Motor Company has opened a branch in Savannah, with Mr. Hazzard as manager.

Herreshoff, San Francisco.—The Reliance Automobile Company is to act as agent for the Herreshoff in this city.

Overland, Trenton, N. J.—J. C. Van-Horn has been appointed local agent for the Overland car.

RECENT BUSINESS CHANGES.

Auto-Car Manufacturing Company.—The truck building firm, the Auto-Car Equipment Company, of Edward street, Buffalo, N. Y., has changed its name to the Auto-Car Manufacturing Company and increased the capital stock to $250,000. It will move into the new buildings at Elmwood and Hertel avenues, May 1. The plant will be one of the most complete in construction and equipment, and will have a capacity for an output of about one thousand machines per year. The Auto-Car Equipment Company has been quoted as the oldest manufacturer of commercial cars in America.

Allen-Swan Company, Brooklyn, N. Y.—Lew Allen, president and general manager of the Allen-Swan Company, the well-known Long Island agent for Stearns cars, has bought out the holdings of Messrs. Kingsley and Swan. He will continue the business at 1384-86 Bedford avenue, and alterations will be hurried so as to fit the place for spring business. Burt W. Phillips will be the new treasurer, and Howard Drakely will continue with the company.

Metropolitan Garage, New York City.—This concern, located at Seventy-seventh street and Broadway, has been purchased by the Monarch Motor Company, which will make numerous improvements and operate it as a high-class storage garage. The garage, which has already made an enviable record, will be made one of the largest and finest in the city.

James L. Gibney & Bros., Philadelphia.—Continental tire agents at 211 North Broad street, have just taken a long-term lease on the double property at 215-217 North Broad street, which is now being fitted up to accommodate their rapidly growing accessories business. The alterations will be completed April 1.

Oshkosh Electric Company, Oshkosh, Wis.—The Oshkosh Electric Company, of Oshkosh, Wis., manufacturers of spark coils, has discontinued business, and its machinery, tools and machinery have been disposed of to various concerns making electrical goods.

Newark, N. J.—On March 15 the official headquarters of the Motor and Accessory Manufacturers, now located in the Union Building, Newark, N. J., will be moved to the Argus building, 17 West Forty-second street, New York City, where the regular business of the association will be conducted.

Kansas City, Mo.—The Ford Motor Company, at 318-320 East 11th street, and the Midland Motor Car Company, at 1608-1610 Grand avenue, are to trade salesrooms.

RECENT BUSINESS TROUBLES.

Motor Commercial Delivery Company of Philadelphia.—Creditors of this concern, with headquarters at 1505-09 Appletree street, have asked that a receiver be appointed for it. The petition states that the company has a total indebtedness of $16,500, with available assets of only $100, apart from machinery, tools, and fixtures valued at $5,430. It is alleged that the company is unable to meet its obligations, is insolvent, and that no assignment has been made for the benefit of creditors.

Pneu L'electric Company, New York City.—A petition in bankruptcy filed against this company, dealers in tires and other automobile accessories, at 1610 Broadway, by attorney for creditors, alleges that the concern is insolvent and unable to pay debts amounting to $3,700.

OBITUARY.

William W. Austin, known as the father of the automobile, died suddenly on March 7 at his home, 37 Shirley street, Winthrop, Mass. At the time of his death, although 85 years old, Mr. Austin was busily engaged in perfecting a late invention, a gasoline lamp. A company, headed by ex-Governor Frank S. Black, of New York, and including as stockholders John D. Rockefeller and others, had been formed to manufacture and market the product. Mr. Austin got his name of "father of the automobile" from the fact that in 1860 he invented and built the first steam auto. During the Civil War he built another that is still in existence and for which he recently refused an offer from the Stanley Automobile Company of Newton, Mass. He was a prolific inventor, having to his credit the steam-propelled bicycle, a sailing catamaran, rubber heels, an airship and many others.

President Taft's White Steamer Leaving White House Garage.

With the advent of the new administration in Washington, D. C., there was also an important change in the White House stable, turning it into a garage, with a gasoline tank displacing the feed bins and from the pegs, instead of harness, inner tubes and casings now hang. President Taft delegated to W. C. Sterling, the Washington representative of the White Company, the task of making the necessary changes. The garage is now in charge of Geo. Robinson, who has been detailed from the War Department to drive the car.

New Quarters of Maxwell-Briscoe Motor Company at 1930 Broadway, New York City.

PERSONAL TRADE MENTION.

George F. Fenno has joined the staff of the Geo. H. Gibson Company, advertising engineers, Tribune Building, New York City. Mr. Fenno is a graduate of Sibley College, Cornell University, and for the past two years has been insurance engineer with the Middle States Inspection Bureau, an organization maintained by 36 of the leading fire insurance companies. His experience in this line has made him widely familiar with engineering and manufacturing plants, a feature which will be valuable to him in his present work of promoting the sale of engineering supplies and equipment by means of publicity.

C. R. Van Auken has been appointed manager of the Detroit branch of the Ajax-Grieb Rubber Company, succeeding C. W. Hatch. Mr. Van Auken has been connected with the tire industry for several years and prior to that time had long experience in the rubber and druggists sundry business.

J. A. Temme, until recently with the Auto Equipment Company of Philadelphia, has been appointed manager of the Boston branch of the Stromberg Motor Devices Company, manufacturers of the Stromberg carbureter.

L. B. Fijux has been appointed manager of the Chicago office of the Willard Storage Battery Company, of Cleveland, and will take charge of the company's interests in Chicago and surrounding territory.

J. Stewart Smith has entered into relations, as general manager, with the Standard Sales Company, of 1779 Broadway, New York City, after several years with Emil Grossman in his various enterprises.

F. W. Suhr is now connected with the Diamond Rubber Company and is located at 223 Columbus avenue, Boston. He was formerly with the Michelin Tire Company as New England representative.

James W. Florida, who drove a Locomobile in the last Vanderbilt race, gave a dinner to his team-mate, George Robertson, in Philadelphia, when the latter returned from New Orleans.

W. R. Stroud, famous as a bicycle racer in days gone by, has just associated himself with the Penn Auto Supply Company, of Philadelphia, and will have charge of the motorcycle and tire end.

Benjamin Gerdelman has been engaged by Gray & Davis as a special representative and will have a salesroom at 4630 Olive street, St. Louis, where he will carry a stock of lamps and parts.

Arthur R. Smith has accepted the position of manager with the new Drummond garage and salesroom for White steamers and Woods electrics, 2024 Farnam street, Omaha, Neb.

J. B. Burwell, former Chicago manager of the Ajax-Grieb Rubber Company, has gone to Minneapolis to take charge of the Ajax branch in that city at 905 First street, West.

TAXICABS AND TRANSIT.

Chicago.—Some one interested in figures has dug up the fact that the city of Chicago has no less than 14 automobiles in service, divided as follows: Police Department, 2; Fire Department, 2; Board of Improvements, 2; Health Department, 2; City Physician, 1; Commissioner of Public Works, 1; Bureau of Streets, 1; Bureau of Engineering, 1; Park Commission, 1; Department of Track Elevation, 1, and Council Committee, 1. Superintendent Doherty's Street Department machine has traveled 97,000 miles in two years. That this is not an isolated record is shown by the additional statement that Deputy Commissioner Paul Redieske, of the Public Works Department, traveled 52,000 miles in a single year—1908. Another machine, recently purchased, has gone 5,000 miles in two months of the winter, which is at the rate of 40,000 miles a year.

Rutherford, N. J.—Three automobile stages, with a seating capacity of thirty each, have been put into service by the Rutherford Transit Company between the Erie Railroad station and various points in the borough. This company, composed mainly of local residents and stockholders, has been recently formed, with a capital of $2,000, to supply proper transportation to the station, and, with a low rate of fare and fixed schedules, it is thought that most of the 1,500 commuters will use the stages. It has been estimated that it will cost $13,870 to operate the three cars yearly, and that the gross receipts will be $16,425, leaving a balance of $2,555.

Girard, Ga.—An automobile line has been established between Girard and Waynesboro, making a daily round trip between these points, a distance of twenty-five miles. Girard does not have a railroad, and this means of transportation is an important one to the town. Regular schedules will be in force with a rate of fare averaging 4 cents a mile. The officers of the company are: President, Charles Brigham; vice-president, W. R. Buxton; general manager, J. B. Heath; secretary-treasurer, W. V. Stephens. A charter will be applied for.

Morristown, N. J.—An automobile chemical engine was recently tested out very thoroughly in the streets here by the Fire Department and town officials. The town is about to purchase a machine for Independent Hose Company, and this one was brought here by the Webb Company for demonstration purposes. The fire extinguishing equipment, consisting of a 40-gal.-long tank, 1,000 ft. of hose, etc., was mounted upon an Oldsmobile chassis.

New Orleans, La.—Automobile patrols are getting so common now that it is considerable of a task to chronicle all of them. The latest of the Southern cities to fall into line is New Orleans, which, with a Studebaker patrol and five police motorcycles, is getting quite up to date. The new machine, which is to be used as an emergency vehicle as well as a patrol, is to be kept at the First Precinct Station.

Cleveland.—Finding it impossible to hold up its end in competition with electric railways on the basis of steam service, the Cleveland Akron & Columbus Railroad is preparing to put on a half-hour suburban service between Columbus and Westerville, using a gasoline-propelled car of large capacity. A large number of cars will be put into service at once.

Tampa, Fla.—A new departure for Tampa will be the installation of a big automobile, equipped with chemical tanks, etc., for fire department service. This move was brought about by the unusually severe service, which wore out the horses faster than the department could afford to buy them.

Brownwood, Texas.—Plans are under way for the establishment of several motor 'bus lines. One is to run between Brownwood and Mays, another to Rockwood, and still another to Mercer's Gap. A meeting is to be called in the near future, and it is expected that $200,000 will be raised for the maintenance of the lines.

Chicago.—The Board of Underwriters has taken delivery of a three-ton fire insurance patrol wagon, made by the Knox Company. This machine, which is of the conventional patrol type, will be put into service at once, working from the No. 3 house at Twenty-third and State streets.

Jacksonville, Fla.—John S. Lane, proprietor of the Ocklawaha Hotel, has started a bus line between the Seaboard Air Line Depot at Tavares and the hotel. The automobile used seats sixteen people and has been very busy ever since it was put into service.

Carlsbad, Tex.—The Carlsbad Commercial Club recently closed the contract with the Midland-Seminole Automobile Company for an auto service between Carlsbad and Midland three times a week and the building of a fine road for this exclusive use.

Fort Worth, Tex.—Beginning March 1, a taxicab service will be installed here. Starting with two cars, the Reid Automobile Company will add more as the service demands it. Two large garages which were recently furnished will be utilized.

Boston, Mass.—The Taxi Motor Cab Company has done such an excellent business of late that it has been obliged to add 50 more cabs; in fact, it is expected that this number will not be adequate for their present needs.

Ormond Beach, Fla.—The Florida East Coast Hotel Company is about to start an auto 'bus service between Ormond, Daytona and Palm Beaches. Three cars have been purchased from the American Locomotive Company.

INFORMATION FOR AUTO USERS

Zig-Zag Tire Chain.—The latest thing on the market in the nature of anti-skidding devices is the Zig-Zag tire chain, manufactured by the Motor Appliances Company, 1438 Michigan avenue, Chicago. The feature of this appliance is that it is in the form of a continuous chain held in a zig-zag line along

ZIG-ZAG TIRE CHAIN APPLIED.

the periphery of the tire. The chain itself is of the well-known twisted-link pattern, with special links disposed at intervals throughout its length. These hooks are so placed in the chain, that when it is laid out in a straight line without twist, they alternately point in opposite directions. These hooks are secured to the side chains at such distance apart as to give the tread member a zig-zag line of approximately 45 degrees to the plane of the wheel.

Great efficiency is claimed by the makers in the line of efficiency owing to the fact that the chains engage the ground in an oblique line, thus equally resisting the tendency to skid sidewise, and aiding traction and brake action. The close proximity of the contact points in the chain brings two of these points on the ground at all times, and it is also claimed that this naturally aids their gripping power and eliminates vibration. These chains have been rigidly tested before offering them to the public. Distributing agencies are being rapidly placed.

Swinehart Twin-Tread Bridge Tire.—After exhaustive tests, the Swinehart Tire & Rubber Company, Akron, O., has put on the market its new bridge tire, a section of which is shown in the ac-

SECTION SWINEHART TWIN TREAD TIRE.

companying cut, and which, the makers assert, eliminates the ragged edges and grinding away of the bridges due to faulty construction in the past. Thorough tests have proven to the satisfaction of the Swinehart Company that bridges in the side of a tire, in the form of cylinders, are practically indestructible, and will stand the greatest amount of abuse without cutting or tearing away from the tire proper. These bridges take up the shocks gradually, offering very little resistance at the beginning, but spread and effectually break the shock as the cylinders are flattened out. This, is claimed, makes a very easy riding tire, and nearly as durable as the regular concave tire.

Foster Shock Absorber.—This is announced as a new and simple device for eliminating excessive spring action without destroying the resiliency or free central movement, and the resisting force is applied gradually and in proportion to the severity of the shock. The stationary base of the absorber consists of an oval-shaped steel cup, the length being one-fourth inch greater than the width. The cup is encircled by a one-piece band of flexible spring steel faced with thermoid liner, which bears against the outer surface of the steel cup, thereby producing the desired friction. The amount of resisting force exerted is governed by one adjusting nut, and can be varied as required. Owing to the oval

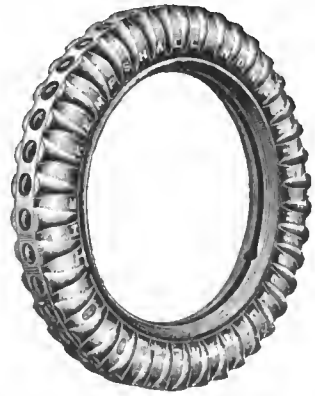
FOSTER SHOCK ABSORBER IN PLACE.

shape of the cup, the central movement is free, and can be varied from one inch to three inches at the end of the arm. In consequence, spring action is free for a corresponding distance, after which the friction is gradually applied and increased on both the upward and downward stroke. As the arm of the absorber moves off the center the flexible steel band changes its shape to conform to the oval cup, thereby creating a gradual increasing friction to conform to the arm movement. All bearings are case hardened to insure durability, and the friction cup is dustproof. The Foster shock absorber will operate from 12 to 15,000 miles before replacement is necessary, and can be applied to any type of motor vehicle. It is manufactured by Claude H. Foster, 1410 East Fortieth street, Cleveland.

Infallible Metal Polish.—Branch houses established recently in Chicago, New York, New Orleans and San Francisco by George William Hoffman, of Indianapolis, manufacturer of metal polishes and other similar specialties, in answer to a demand in these sections of the country, is regarded by Mr. Hoffman as an indication that standard polishes are wanted not only by autoists but by other people as well. The substance is put up in paste, liquid and powdered form, so that it meets any requirement, and is suitable for use on gold, silver, plated ware, nickel, tin, brass, copper, etc., removing stains and producing a brilliancy equal to newness. Mr. Hoffman suggests it as especially useful in cleaning automobile brasses, band instruments, locomotive and machine mountings, kitchen utensils, metal street signs, show cases, scales, headlight reflectors and many other like articles.

Keystone Grease.—At the automobile shows recently held in New York the stand of the Keystone Lubricating Company, Philadelphia, contained a convincing exhibit showing the special adaptability of this company's product to automobiles. The exhibit consisted of a combined differential and change-gear, lubricated with the No. 3 density grease. The mechanism was driven by an electric motor, and was conveniently arranged to permit a good view of the gears running in the lubricant and show the unique properties of the latter. The mechanism is of the roller-bearing type, and is effectively lubricated, it is stated, by a charge of ten or twelve pounds of the grease. In operation the latter sticks fast to the rapidly revolving parts, forming a thick glib which penetrates between the teeth of the gears and resists being thrown off by them. Moreover, the motion of the gears causes a slow but positive circulation in the body of the grease, which means that every part of the mechanism is permeated by a constantly changing flow of lubricant. The clinging consistency of this grease is stated to be such that the moving parts of the mechanism, instead of making a cavity in the body of the lubricant or clearing themselves of it, as they would ordinarily do, remain smothered in it, so to speak, at all speeds. This property of "sticktoitiveness" is, it is claimed, accompanied by the lowest attainable coefficient of friction, and by perfect chemical neutrality and freedom from corrosive substances that might injure the gearing. It is also stated that the consistency and lubricating quality are unaffected by the wide temperature variations that naturally obtain in automobile work, ranging from exposure to zero weather with the car standing still in winter to the maximum running temperature of the gears on a hot summer day.

English Non-skid Tires.—Cryder & Company, of New York City, are importing the Kempshall non-skid tires which are made in England, with the skid-preventing qualities molded right into the tire, without the use of steel or leather. They are built with a flat tread in which are suction pockets that increase their efficiency, and being low



KEMPSHALL IMPORTED NON-SKID TIRE.

pressure tires minimize vibration and increase comfort. With plenty of the best rubber and fabric, they are said to be nearly immune from punctures and other troubles, ten to twelve thousand miles often being gotten from the one tread.

INDEX TO ADVERTISERS

VOL. XX NEW YORK—THURSDAY, MARCH 18, 1909—CHICAGO No. 11

THE AUTOMOBILE

Over Muddy Roads from the Metropolis to the Hub

OVER roads which included good and bad and still suffered from Winter's onslaught, mud-bogged in some parts of Connecticut, and more uniformly acceptable in Massachusetts, the route was a trying one for the twenty contestants who participated in the endurance run, held March 11, for the Chester I. Campbell trophy. Fourteen made the difficult journey from New York City to Boston with absolutely perfect scores, necessitating a drawing for the handsome prize cup. This will be held at an early date at a luncheon given by L. H. Perlman, the first winner of the trophy, to all the contesting drivers and entrants. Of the cars penalized only two had large scores marked against them, and these were caused by the heavy condition of the roads in some parts of the route.

W. W. Burke in his six-cylinder Mora, A. B. Cordner in the six-cylinder Acme driven by Patchke, A. D. Hall in the Matheson touring car, C. S. Carris in the six-cylinder air-cooled Franklin, Guy Vaughn in the Stearns stripped tourabout, Albert Knox in a 38-horsepower Knox, V. F. Pisani in the Zust, Ray McNamara in a Premier, M. W. Batts in a Stearns, C. S. Rothfuss in a Matheson tourabout, L. R. Burne in a Cadillac tourabout, J. I. Miller in a stripped Cleveland roadster, H. A. Street in another Cadillac and C. W. Kelsey in a Maxwell were the successful competitors who kept their clean scores throughout. The penalties inflicted upon the Lozier, 2 points, and the Renault, 16 points, were promptly protested, but neither allowed by the referee, the others taking the marks as given, the Haynes 6 points, Coates Goshen 50, the KisselKar 165 and the Atlas 200.

As means of arousing interest throughout New England in automobiles, in addition to the Boston show, this event was just what it had been intended to be, a successful one, and the fact that so many cars were able to complete the 243 miles in such a short period of time was a matter of pleasure to everyone connected with the great show, just finishing. All along the route there were crowds of people who attested to their interest by waiting on the streets, or, if at controls, by surrounding the muddy machines and crews.

The morning of the start from Columbus Circle was a very cold one, as compared with the warm weather of the day previous to it, but all of those who had entered machines appeared except one, a National entered by W. C. Poertner, and were sent away at one minute intervals by Starter McMurtry, with the managers of the event, Mills and Moore, watching the proceedings and ready to help in getting the automobiles away. Of course, the route in leading out through the greater city was generally over paved streets and the fine macadam on Jerome Avenue, Fordham Road, and the Pelham Parkway, to the old Boston Post Road, and on this the trouble began. Deep, slimy mud flew over everyone, in the sprays of water thrown from ruts by the

Where the Cars Started at Broadway and Columbus Circle.

At New Haven, Where the Cars Checked In at the First Control.

flying wheels, and the surface underneath the mud was so rough that it threw the machines from side to side and bounced the passengers around. A twenty mile an hour schedule had been mapped out, with the first control at New Haven, making car No. 1, Burke's Mora, due there at 10.30. Before the contestants had gone very far they realized that they must travel as fast as possible over good roads in order to go slowly over the worst ones, on account of the deep mud.

Through the suburban resident sections of New Rochelle, Larchmont, Mamaroneck, Rye, Portchester, into Connecticut and on through Greenwich, Stamford, Norwalk, Fairfield and Bridgeport the route took the cars and there were many people all along the way. Near Fairfield an unfortunate occurrence happened when a horse was badly frightened by one of the cars, and a rich Bridgeport manufacturer, A. W. Wallace, in attempting to jump out, was killed. Paul Lacroix, who was driving his 35-45 horsepower Renault in the run, was blamed for this, though he professed that he did not cause it, and knew nothing of it until informed by New Haven police. His number was phoned ahead to Bridgeport and the authorities there tried to stop him with an American flag, but thinking that this was a part of the general celebration he brushed by, and so was held for a few minutes at New Haven. Unfortunately the flag was caught by the car and damaged, and the police of Bridgeport added the charge of publicly mutilating the national emblem to that of reckless driving preferred by other places. At a hearing a few days later, Mr. Lacroix was fully exonerated, not only of the blame in connection with the death of Mr. Wallace, but also of wilfully damaging the flag. It was brought out that the flag was not unfurled when waved, consequently it could not be distinguished from a piece of red bunting, and, moreover, the policeman who handled it was not in uniform. Mr. and Mrs. Lacroix, however, presented the authorities with a new emblem to replace the one lost. At Fairfield there was no trial, those in charge of the prosecution having satisfied themselves, from the previous examination of witnesses, that Mr. Lacroix was not implicated. This trouble cost him his clean score. Inasmuch as his protest was not sustained by Referee Bradley, Mr. Lacroix has protested to the Contest Board of the A. A. A., claiming that he is penalized for an accident probably caused by another car.

Over an hour before the Mora was due at the first checking station, Albert Dennison, who has figured as a Knox pilot with Bourque in their many victories last season, was one of the first in, sharing the honors about evenly with the Acme driven by Cyrus Patchke, who drove the Acme in the Vanderbilt race, and won second place in the Fairmount Park race. Burke's rumble seat and tool box loosened in the bumping along the New York and lower Nutmug State roads and he had to stop to fix it. The only car which did not reach the first station was the Atlas, which was being driven by C. H. Beecher, and as it did not report at any station its penalty was placed at 200 points. No little trouble was found by the contestants a number of times in finding the route into strange towns, not following the route book closely enough and in one or two cases a change from these books had been made. All the cars had some time to wait on the Yale campus, and the travelers spent it in discussing the bad roads, and in wondering what would come next. The two men in the Cleveland car, and those in the Haynes were sources of much merriment to the onlookers because of the coating of mud all over them. Their cars did not have rear fenders and the tire changes threw a plaster over them, front and back.

The Halt at Hartford, Where Lunch Was Served to the Hungry.

A short control was that from New Haven to Hartford, only 42 miles, and Burke was due there at 12.36, but even in that short distance with none too good roads, the drivers were able to make up enough time to give them half an hour for lunch at the Heublein, arrangements for which had been made by J. K. Mills, who preceded the cars by rail. From Hartford to Springfield was absolutely the worst run of the trip, although there was no control in the latter city, for the roads were terrible and as one veteran of Glidden tours said, "There was about twenty miles of 'Crocker, Indiana,'" and those who participated in the 1907 tour knew what was meant. Perhaps only Road Commissioner MacDonald can explain the methods of road construction from Winsor to Thompsonville and thereabouts, where roads deep in mud were being covered deep with sand, so that it was impossible for the cars to go

through them without difficulty. As big and powerful machines as the Mathesons and the Stearns had to use their low and second speeds, and the first three cars through, the Mora, Hall's Matheson and Vaughn's Stearns, took to the trolley tracks as a better highway. From Springfield into Boston, however, there was no trouble, many of the roads being in remarkably fine shape for this time of the year.

The control next after Hartford was at Worcester, where the local automobile club had affairs in charge, and it was a run of 79 miles, with 42 miles more to cover into Boston. At Worcester a number of Boston autoists met the muddy caravan, Watson Coleman, of the White branch, and R. H. Johnston, of that company, acting as pilots in a large White car, and a number of other machines joined the party. It was just getting dark as the cars entered Commonwealth avenue, but they had no trouble in reaching their destination in front of Mechanics Building where they were checked in. The accident at Fairfield had caused the authorities from Worcester into the finish to be stricter even than usual and so no high speed was attempted by the contesting drivers. In most places, however, there was little opposition to seeing the cars go about as fast as possible.

Fourteen cars in a deadlock out of twenty was not a pleasant outlook for those who wanted the run to decide a definite winner, but on the other hand, it generally pleased the trade, as showing what the cars are able to do, in this kind of weather, on bad roads, when kept going at high speed. The cars and men taking part in it made up a really representative assortment, more so than was expected when the event was gotten up on short notice. The machines all seemed to be good ones and well able to undergo the test again, at once, without further preparation than oiling. In the lists of cars there were some which have been in the public eye before, the Stearns, which Guy Vaughn drove, being the same one used in racing, the Maxwell, driven by Kelsey, being the one entered in the Fairmount Park race in Philadelphia, the Premier, driven by MacNamara, being the one which finished the Quaker City Motor Club January run with the only perfect technical score, the six-cylinder Mora being the first of that type built by the Mora Company, the Cleveland being one which raced on tracks around New York City last fall, and several other cars have been especially prominent. The big Matheson touring car, driven by Hall, was the only seven-passenger car in the run and it was well up with the leaders at all times, starting fifth and generally finishing third at controls.

The contestants often ran in groups, the first one composed of the two Stearns, which were very fast, the Matheson touring car, the Mora roadster and the Acme tourabout. The Renault also gained the reputation of being extremely fast, but it was delayed by the police and had a handicap to overcome. Pisani, the Zust driver, was criticized by others for his recklessness, and his way of running at about forty miles an hour and then turning around in his seat to see who was behind, so that once in doing this he had to make a quick application of his brakes and nearly precipitated a mix-up between himself, Guy Vaughn and Hall's Matheson. C. E. Force had his Lozier car stripped and driven by Ralph Mulford, and these two were well plastered with yellow clay before they had gone very far. Kelsey showed the speed of his Maxwell between Hartford and Springfield by passing fifteen cars and coming in about fifth instead of twentieth. The two Cadillac cars, the KisselKar and the Coates Goshen took the run very easily, though the latter ones had to stop and were late, the Coates Goshen at Boston and the KisselKar at New Haven. Carris in his six-cylinder Franklin took the run easily but fast and was one of the first into the Worcester control. His was the only air-cooled car in the contest, and as is usual, had no reason to fear any trouble from that score. One of the largest cars was the Matheson tourabout, a four cylinder one, driven by C. F. Rothfuss, which made a perfect run throughout the trip.

There was some discussion as to whether there would be a run-off but the entry blanks stipulated that in case of a tie there would be a drawing for the trophy, and that would have been held on Friday but for the fact that the Referee, L. M. Bradley, of the A. M. C. M. A., decided to wait until he found out what would happen to Lacroix. The Lozier entrant protested because of a mistake claimed to have been made by the checker at Worcester in sending him away two minutes out of order.

The latter part of the run was marred by an accident in which E. P. Blake, the New England Jackson agent, F. Ed. Spooner, the photographer, and C. P. Richardson, of New York, were involved. They went out to meet the contestants and while coming back, in Marlboro the car turned turtle, throwing out the occupants. Messrs. Spooner and Richardson suffered merely from shock, but Mr. Blake was taken to the hospital, where it was stated that his injuries were not serious. The result of the run caused much jubilation among the tire men. Guy Vaughn's Stearns was equipped with Continentals; the Renault, Zust and two Mathesons had Michelins; the Premier and Franklin had Goodrich, and seven others had Diamonds.

Chairman Frank B. Hower, of the A. A. A. Contest Board, sent out to Worcester a pacemaker to lead the cars into the finish, in Glidden Tour fashion. One of the cars in the run left Worcester about five minutes after the pacemaker and averaged at least 35 miles an hour over roads where there was little or no traffic, and never once caught up to the pacemaker. Those familiar with past Glidden Tours saw little difference between the speed of the run from New York to Boston and the annual A. A. A. event, for there was no more speeding then than in the annual mid-Summer national contest.

PHILADELPHIA CHAUFFEUR GETS ONE YEAR.

PHILADELPHIA, March 15.—Irresponsible chauffeurs and owners who are inclined to dally with the local speed laws, to the possible injury of their fellow-citizens, were startled last Friday when Harry Brutslin, a local chauffeur, on trial for running down and injuring Miss Ada Fadeley, on October 31 last, was convicted of aggravated assault and battery, and sentenced by Judge Sulzberger to one year in the county prison.

Before sentencing Brutslin, the judge said that conditions required that he should be made an example. "Men such as you seem to forget that the streets are for the use of all the people. Under the local police regulations all trolley cars are required to come to a full stop on the near side of every cross street, and it is the duty of all other vehicles, and especially automobiles, to do the same. The tooting of a horn is only an aggravation of the offense of reckless speeding, as it tends to confuse and perplex a pedestrian."

The holding in bail, in the large sum of $2,000, of A. M. Van Osten, who ran down Edward S. Vaughn on February 19, and who has since been sued by the latter for $10,000, is additional evidence that the announced determination of the local judges to put a stop to the overspeeding habit is no "fairy tale."

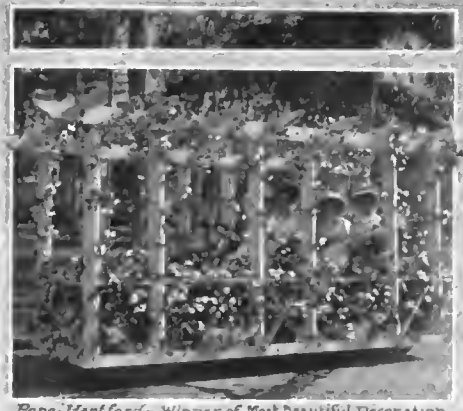
DETAILS OF DETROIT RUN COMPLETED.

DETROIT, March 15.—Details of the second annual reliability run of the Detroit Automobile Dealers' Association, which will differ materially from last year's event, have been completed. Detroit will be the starting and finishing point on each of the four days' runs, the machines being parked at the Hotel Tuller each night. The addition of another day will also make the contest more strenuous, although that will be more than offset by the advantage of not having to spend a night in a country hotel, where accommodations are far from first-class, as was the case last year.

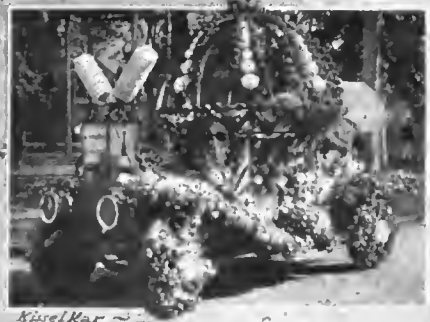
May 10-13 are the dates selected for the run, the first day's journey being to Port Huron and return, taking in Mt. Clemens, Marine City, Ste. Clair, Capac, Romeo and Utica. The second will be to Jackson, Adrian, Tecumseh, Saline and Ypsilanti, thence back to Detroit. The third day will be to Pontiac, Lapeer and Flint and return, and the fourth to Lansing and return. A large number of entries are promised.

HAWAII'S ANNUAL FLORAL PARADE

"Kawaiahao" Semina Ryi. Stevens-Duryea "The Manoa Rainbow"



Pope-Hartford—Winner of Most Beautiful Decoration.



Kissel Kar—That Won Prize for Harmonious Color

WASHINGTON'S BIRTHDAY has come to be the one big fête day in Hawaii, and this year was no exception to the rule. The floral parade at Honolulu was witnessed by the largest crowd of spectators in the history of the event, these including representatives from eight or nine nations. A conservative estimate of the number of tourists places this at two thousand, many of them having timed their visit to coincide with the big "doings."

The parade was larger than any previous year and was materially assisted in the making of a fine impression on the tourists by perfect weather. The character of the designs and decorations of the entrants was fully up to the high standard set in previous years. The entries were spread evenly over five classes, but the first, largest and most important was the automobile division. In this four prizes were awarded to the best float, most original decorations, best runabout and best touring car. Great zest was given to the affair by the capture of the last-named prize by the Japanese Consul-General Uyeno. This was intended to show the existing "aloha" between America and Japan, the idea being expressed by the use of suitable flowers. Thus the meaning of the combination of American Beauty roses with the cherry blossoms of Japan was plain to all.

The judges were all visitors, "malihinis" in the native tongue, and were chosen from among the guests at the various hotels. Their work, always so difficult, was splendidly done, and no adverse comment was heard. One source of regret, however, was the small number of prizes, relative to the large number of contestants.

One of the most daring designs, and one that showed the careful work of preparation, was the float entered by the crew of the naval tug Iroquois, this being a nearly life-sized duplicate of the tug. The whole conception was splendid and was worked out to the smallest detail, even the lifeboat, filled with calla lilies, swinging from the davits.

A car of equal interest was the National car, on which the color scheme of red, white and blue was worked out in carnations, daisies and asters. Balloons of the three colors floated above the car, the body of which was covered by flags and flowers. This was cheered all along the line of the march. Another semi-patriotic float, and a very appropriate one, represented what happened to George, meaning George Washington, of course. This presented a Mount Vernon tableau shortly after the cherry tree was no more, and showed the paternal Washington, birch in hand, and the disconsolate son preparing for the worst.

The beautiful decorations and costly floats were not confined to the automobile division by any means, the wagon and bicycle classes revealing many artistic productions. In the latter the Japanese, with their clever designs, captured a majority of the prizes. Most of these were fishes or animals.

The wagon float which took first prize was that entered by a well-known musician, and was intended to represent Music. It was an exquisite creation of violet and white paper flowers, surmounted by a lyre in the same colors. The harness was wrapped with purple, contrasting with the horses, while all of the occupants were costumed in harmony with the color tones of the float.

In the evening a street carnival of the Mardi Gras order was held. This was an innovation this year, but the spirit in which it was received and the fun everyone had out of it, without any roughness, insured it as a permanent feature of future carnivals. The Elks and the Fifth Cavalry boys helped greatly by turning out in large numbers and with a fine lot of original ideas in the way of costumes.

The day was fittingly closed by an elaborate masked ball at the Alexander Young Hotel roof garden. The costumes were surpassingly beautiful, and the roof garden, with its lights and floral decorations, showed up at its best. The attendance was large and was a merry jostling crowd of fun-makers, who danced and danced until the musicians were tired, and even then called for more. After it was all over everyone voted it the most elaborate and by far the most successful of the Washington Birthday celebrations which have been held in Honolulu

INVOLVING ROAD RACES AND LEGAL SPEED

By E. P. CHALFANT, General Manager A. L. A. M.

THE public must now realize that automobile contests are in their infancy. However, the most expert men in the business cannot tell what turn the sport is going to take next. The whole manufacturing world is divided on the subject of racing. One maker says the sport is of no benefit to the industry; another says it helps more than anything else. Some favor a speedway, but urge the importance of practical contests.

Racing undoubtedly has a very material function in mechanical progress. It develops the art of driving specifically, and executive ability broadly. It has a great human interest, which will not and should not be suppressed. It is undoubtedly the supreme test for one thing, and its excitement and interest have proven of such a nature as to draw the biggest crowds ever seen at any sporting event. The road race naturally stimulates the strongest efforts of the designer, the draughtsman and the manufacturer. To continually improve the result to the limit of skill is to gain for the factory and the industry.

Healthy growth and development can, however, proceed on no other than rational lines. The members of the Association of Licensed Automobile Manufacturers have done much to encourage rational contests and keep them within proper bounds.

Recently in various parts of the country challenges to speed and endurance contests on the public highways have been issued. Wherever such contests involve a violation of the village, town, city or State speed laws, obviously they should not be tolerated. The inhabitants of the territory passed through at an illegal rate of speed may very reasonably have a feeling of bitter and retributive resentment, which may very possibly record itself in positive legislative action, which will oppress the fair-minded autoist and militate against the interest of the automobile industry as a whole, and impede the normal development of mechanical road traction. Such short-sighted affairs can only tend strongly to precipitate contemplated adverse laws in the form of bills proposed in the various State halls of legislature, or, unhappily, to defeat the passage of such liberal legislation as may have received some encouragement. There was an instance of the last mentioned kind in a State nearby recently.

It is impossible to foretell what may be the result of any "cross-country" road race at speed. It is difficult to run a race in which speed is not used, no matter how the driver may be limited in action. Invariably speed laws will be broken.

Let us consider the worst effect of all. Motorists in this country, assisted by a good many other people, are doing their utmost to get good roads appropriations through State legislatures and Congress. The violation of speed laws can only alienate friends in this field and prevent the making of new ones. It should only be necessary to recall to any forgetful mind that good roads are largely the sine qua non of autoing.

If road races must be run, a twenty, thirty or forty-mile course should be arranged for by consent and according to law; and be properly protected and policed during the conduct of the race. Doing anything else is worse than unkindness to a dumb animal. The automobile can easily survive conflict with its legitimate enemies Nevertheless, it should be protected as much as possible from its unwise friends. Many of the members of the Licensed Association have consistently supported sensible contests and will continue to do so.

Incidentally, special challenges are seldom justifiable. There are opportunities enough to race on properly guarded courses in due observance of law.

A reliability contest, of not more than a day's duration, over recognized automobile thoroughfares, conducted by promoters who obligate themselves that speed laws will not be violated (safeguarding this obligation by proper controls), can result in the fair promotion of the sport, and in properly testing out new models for manufacturers, particularly when such contests are held under difficult road conditions. A notable case in point is the contest held between New York and Boston this month, the controls being so well placed as to make it practically impossible to exceed the country speed laws of twenty miles an hour.

"THE MORE THE HASTE, THE LESS THE SPEED"

By CHAS. E. DURYEA.

CONTEST time of year is nearly here. Races, tours and hill climbs will be the menu generally as heretofore. Yet everybody knows that speeds on the level and up hills are faster than there is any call for. No sane buyer cares to rush the hills at dangerous speeds. The gain does not pay for the cost in fuel, tires and other things. Same with road speeds. Our lawmakers are trying to discourage more road speeds and are hitting the innocent with the guilty. Rather more, in fact, for it is the slow-going law-abiding driver that gets caught while the scorcher gets away. And still we inaugurate such contests and fan the flame which destroys our rights. And to what good? Everybody knows now that speeds are a matter of price. Pay enough and the rig can be built that will beat anything gone before. But what is the use?

The average man claps his hands, as at any fireworks, and buys something he can use. Makers who have goods to sell ought to encourage this kind of man. Why does not the awarding of hill-climbing prizes to the rig which gets the lowest product of time, multiplied by price, solve the problem? This is certainly what the buyer wants. Low time and low price. It is easily figured. The man at the roadside can get the result, just as he now pulls his cheap watch on the time only. It would therefore be a popular way of judging. But it needs a little agitation.

Why not coasting contests? These would show the efficiency of the mechanism. Let the hill be coasted with clutch set and spark and throttle off. Oil, brakes and everything else normal. Then the man learns whether he is wasting fuel turning mechanical parts or using it to propel his vehicle. Efficient size of wheels, efficient tires and all such parts would figure in such a test, and the buyer would learn something practical. Tests by coasting with clutches disengaged would also show up the efficiencies of the various transmitting devices quite well. But in such tests it would be necessary to classify according to type of transmitting mechanism or rigs like the Duryea buggyaut, which has no parts turning when coasting except the ball bearing vehicle wheels, would have an immense advantage. There must be an enormous difference in the fuel costs of a vehicle which can be towed by a pull of three to five pounds and one which requires thirty to fifty pounds, as many rigs do. The coasting contest brings this out in such a way as to disclose the real utility of an automobile, reflecting stability as well.

A towing contest would do this also, but not so easily and simply. Yet I do not see why our able committeemen having such contests in charge cannot devise rulings which will bring out the things practical buyers need to know, and leave in the background the facts already too well known. Forget the "cannon." Fourth of July does not come frequently. Give us something that will put meat in the pot. Then, give us the pot, and let us have the fire, but refrain from marking sizzle all over the aggregation as if, indeed, we have lost the process by which we can be calm and cool, or, better yet, sane.

Safety and Utility of Automobile Steering Systems

By Thos. J. Fay

Part II

STEERING is not necessarily a safe enterprise because speeding on curves is avoided. Speeding on a tangent (in a straight line) has the disadvantage of making it difficult to steer clear of an obstruction if, perchance, the speed is so great that the car cannot be stopped in time, and if room is not afforded sufficient to clear the obstruction.

Applying the brakes will be of no value at all when the speed of a car is so great that it cannot be stopped within the distance afforded. True, a car can be slowed down, and in so doing take advantage of the brakes and all possible. When the brakes will no longer serve it is then a question of steering only, and since it will be difficult to avoid a collision under such conditions, the question is, what will be the safest course? There is no actually safe way, since, presupposing a case in which a car cannot be stopped, is admitting that an obstruction will be collided with, assuming it is in the way.

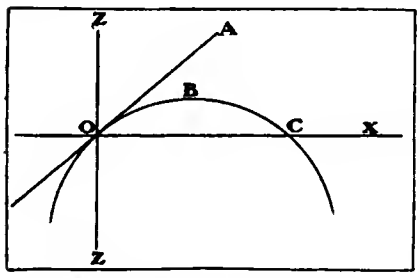

Fig. 9.—Diagram of unrestricted projection of bodies in atmospheric air.

It would be easy enough to say, do not go so fast that the car cannot be stopped within the allowable distance. But this is so self-evident as not to require any attention, and the other side of the question has its serious phase. Attempting to turn out after it is found that the speed cannot be checked is dangerous, since if a car turns over it is likely to do more damage to the occupants than as the direct result of a collision, if the same is intelligently courted.

High Speed Will Cause a Car to Capsize.—The chart, Fig. 8, shows under what conditions a car will capsize if the speed is too high, and if the turn is short enough to introduce a sufficient turning moment. The chart shows, for instance, that if a car is turned on a 50-foot radius it will capsize when it is going at 26 miles per hour, in round numbers. In this case it is assumed that the car is well designed, and that the road is level and hard. If the road is slippery, it is then that the car will skid until the wheels take a "purchase" against some obstruction, and then the car will capsize. The end will be the same in either case, and the method is not to be recommended.

If a turnout (which really amounts to speeding on a curve) is so fraught with dangers, the question is, what is the best thing to do? If, in an emergency of this kind, the car is steered straight ahead in order to prevent turning over, and if a collision follows, the main point is to so direct the collision as to be sure of a clear space ahead in which to shoot out of the car and travel the greatest possible distance in the air, unobstructed, before landing.

Safety Lies in Leaving the Car.—Following the law of the unresisted projectile seems to be the safest course, and, as Fig. 9 shows, the performance will be in obedience to a compound of vertical motion of a falling body, and of the horizontal motion due to the horizontal component of its velocity of projection. In the figure, let O represent the point of projection (the seat of the car), and while it will be impossible to tell the "elevation" of the path, let the direction OA indicate an upward inclination. In this way it will be feasible to say that the path OA as it relates to OX will be at some angle. Let the angle $XOA = \theta$. The horizontal increment will be equal to

$$(5) \ldots\ldots V \cos \theta$$

The vertical (downward) increment will be

$$(6) \ldots\ldots V \sin \theta$$

When

V = velocity of projection, so that, at the instant of projection, the two components will be in the relation as above given.

Gravity influences the situation in accordance with the gravitational laws, just as would be the case were a motorist to fall out of the seat to the ground, the vertical distance from the seat to the ground, and the fall will be no more damaging if the same motorist shoots ahead for whatever the distance may be, complying with the law of "unresisted projectiles." The time interval during the projection will be that required for the motorist to fall to the ground direct from the seat. The distance that the motorist would shoot ahead could be worked out, but it would be of small avail. In one case that the author had a chance to examine into closely the distance was 69 yards, in which case the motorist was not hurt, *for the reason that he did not strike anything while going through the air more resistant than the air.*

In an emergency such as this it would seem as if it is better to select the collision point with a view to accepting the projection, rather than to turn out, and in so doing be sure of turning the car over with good chances of landing under the same. The main reason for thus attacking the subject, however, is to clearly indicate that it is not safe to drive under conditions which will not allow the motorist to see ahead far enough to allow him to judge of the nature of the road if the speed is so high that the brakes will not serve for the purpose of quickly arresting motion, thus making it absolutely a question of steering.

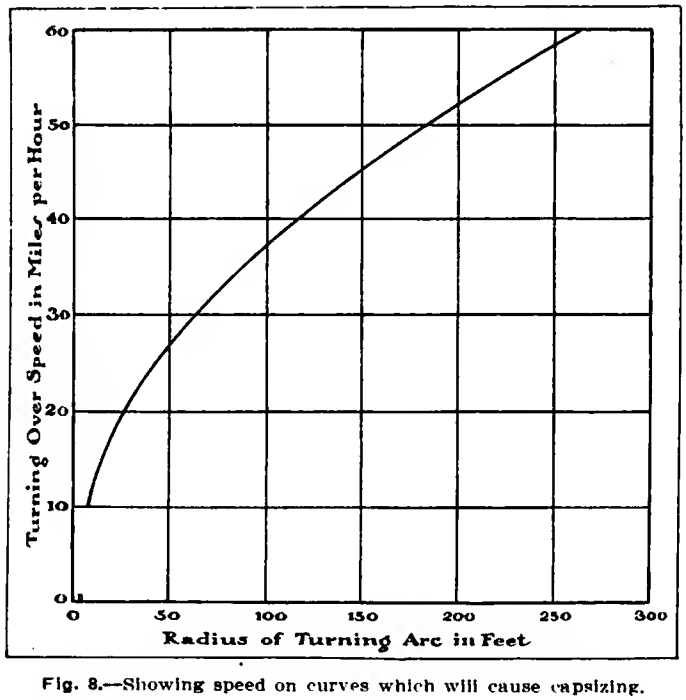

Fig. 8.—Showing speed on curves which will cause capsizing.

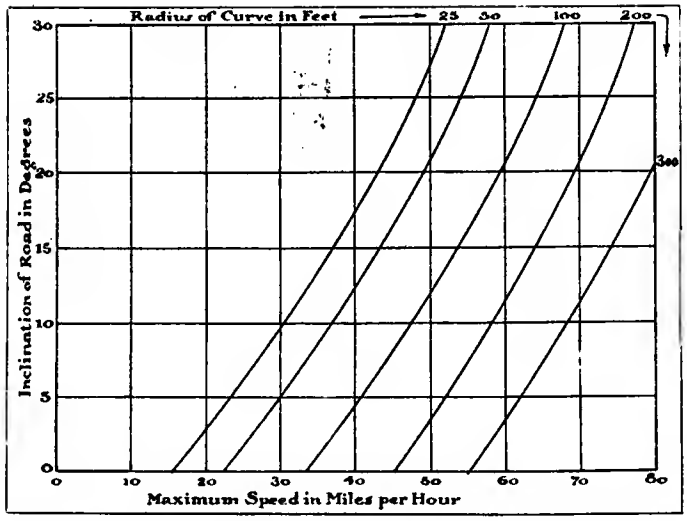

Fig. 11.—Curve showing advantage gained by banking roads at turns to suit different speeds.

That the future will hold some improvements in this connection is shown by the latest devices abroad*, in which air is used to help snub motion, and since the air is in no way connected to the question of adhesion of the tires to the road, it follows that air brakes will put a new face on the situation and possibly shorten the distance in which motion can be arrested. Fig. 10 gives information in relation to the resistance offered by air to the transit of a body, and the chart will apply in two ways to the point to be here made. As the chart shows, if a car is going, say, 60 miles per hour, the wind resistance will be between 13 and 14 pounds per square foot.

Air Propellers Will Serve for Brakes.—If an air propeller will serve to drive an airship, which is a settled fact, the same air propeller will serve to stop a car, and it matters not at all if the car is going through the air or rolling over the ground on wheels. If the car is rolling over the ground it will be possible to snub motion with the idea of reducing speed to a safe point, in view of the road condition (a) by using the brakes up to the limit of the tractive ability, and (b) through the use of the wind brakes, which will work whether the wheels slip or not.

It is this same wind resistance which enables one to be projected out of a car and land at a considerable distance ahead without being seriously hurt. The energy is expended in overcoming wind resistance, and the end is that the fall to the ground from no great height is all to be dreaded. On the other hand, it is of the greatest importance to select an unobstructed orbit, if such it may be called, to avoid impact with some obstruction, since such a contingency will result in another story.

Wind Resistance Must Be Taken Into Account.—To show that wind resistance is quite an effective phenomenon to encounter it is only necessary to take into account the result of the pressure at 60 miles per hour as before referred to. If the resistance is fixed at, say, 13 pounds per square foot, and if the front area of a car is 10 feet, the instantaneous value of the horsepower increment will be fixed by the formula,

$$(7)\quad \text{H.P.} = \frac{PA\ (M\ 5{,}280 \mid 60)}{33{,}000} = 0.96\ PAM.$$

When,

H.P. = Instantaneous value in horsepower;
P = Pounds per square foot pressure due to wind;
A = Front area of the body in square feet;
M = Speed in miles per hour.

As a practical demonstration of the formula, assuming that the front area of a car may be 10 feet, if the speed is 60 miles per hour, the wind resistance will have the equivalent value as follows, almost without respect to the shape of the front area against which the wind must beat—nor does it seem to make any difference whether the surfaces are at the front of the car, or to the back:

$$\text{H.P.} = \frac{13 \times 10\ (60 \times 5{,}280 \mid 60)}{33{,}000} = 20.8.$$

Thus far the discussion has taken into account hard, level roads. If roads are "banked" on curves it is quite another story that may be told, for then the speed can be increased as Fig. 11 will show. As the curves look, if the inclination of the embankment is 20 degrees, and if the curve is at a radius of 300 feet, the speed can be 80 miles per hour, which is a very considerable increase over what can be allowed if the road is level. On a level road it was shown in Fig. 1, Part I, of this article that the speed could be but 53 miles per hour with the same radius of curvature, *i.e.*, 300 feet.

Banked Curves Make for Safety.—Another look at Fig. 11 will show that decreasing the radius of the arc of turning has the usual effect even if the road is banked, in that the speed must be lowered if the radius is shortened. If the radius is, say, 100 feet, then a 20 degree inclination of the embankment will allow of a speed of about 60 miles per hour. Of course these speeds sound high, but by dealing in high figures it becomes possible to accentuate the points to be made. It is also true that banking should be in excess rather than restricted in the cases requiring attention with a view to increasing speed.

Camber of Roads Puts a Different Face on It.—Unfortunately, roads, instead of being embanked, are cambered (with a crown at the center) in the manner as shown in Fig. 12, the amount of the camber differing in the several localities, and under varying conditions. The "crown" or camber of the road is quite pronounced on many "pikes" as to become a menace under certain conditions of steering. The general formula of the crown which would serve well for drainage purposes in practice is given as follows:

$$(8)\quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots O = C\left(\frac{D}{R}\right)^{s},$$

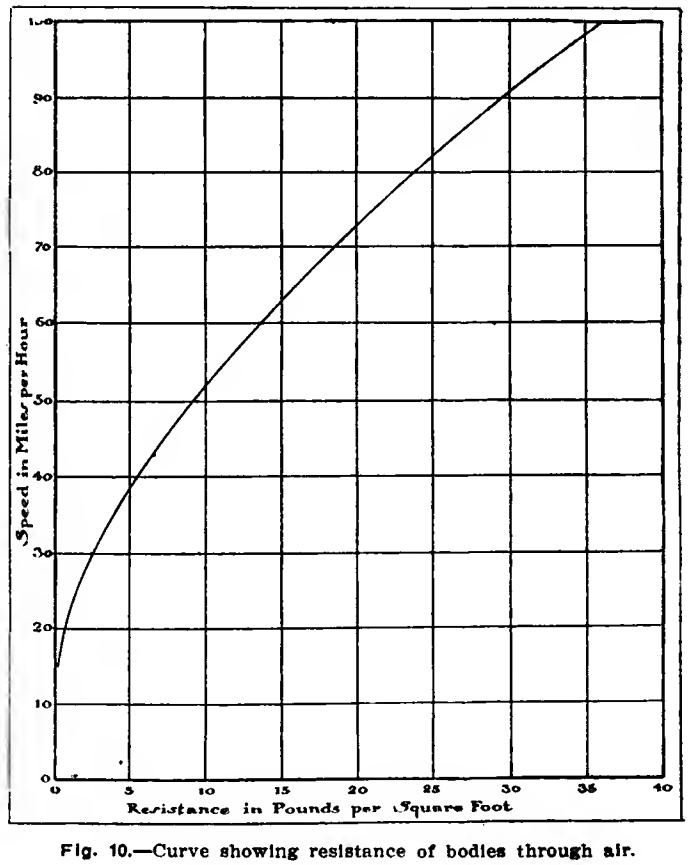

Fig. 10.—Curve showing resistance of bodies through air.

Note: See article by W. F. Bradley, entitled "Just Out of the Shops Abroad," in this issue of "The Automobile," in relation to the subject of wind brakes.

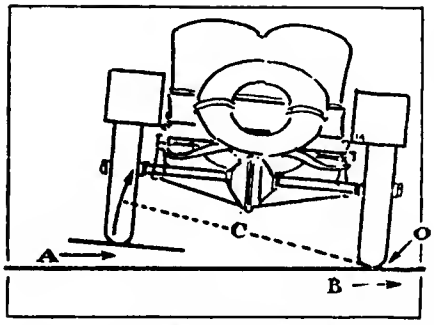

Fig. 14.—Diagram showing how in-wheel loses traction on a curve.

When,
O=Ordinates in inches;
C=Crown in inches;
D=Distance in feet from center of the road to the ordinates, in each case;
R=One-half the width of the roadway in feet.

Taking into account the camber of the road and the fact that, in turning, the off side of the road is used, it is plain to be seen that, instead of an embankment, it is a declination that will be used. The effect of this declivity is the reverse to that of an embankment, as the curves, Fig. 13, show. Looking at the curve will show that on the 5 degree slope (downward) the safe speed is reduced to 24 miles per hour, approximately, if the radius of the turn is 100 feet. The same turn can be made at a speed of 32 miles per hour if the road is level, as the curve also indicates, and with an embankment of 5 degrees it is shown in Fig. 13 that a speed of 38 miles per hour will be safe. Obviously, much depends upon the slope of the roadway at the point of turning, and if the slope is declining, provided the radius of turning is short, it is anything but safe to make the turn at a very high speed.

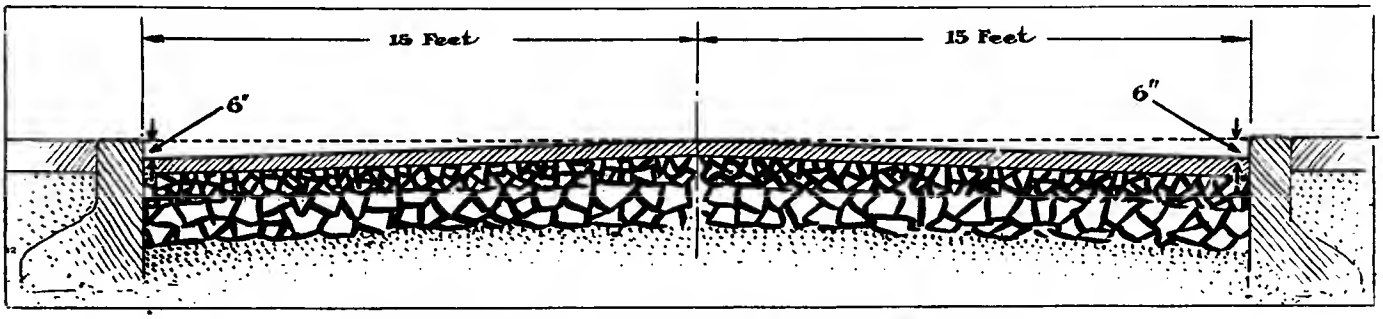

Fig. 12.—Cross-section of roadway showing effect of crown on turning.

Tractive Ability Declines Rapidly.—Since steering really depends upon the tractive ability of the wheels of a car, it is of interest to note that the traction decreases as speed increases, and on a curve, where the traction is the most needed, the in-wheel leaves the road if the radius of turning is short or if the speed is high. Fig. 14 shows something of what does happen, assuming in this case that the car is being viewed from the rear, and making a turn to the left. The in-wheel will leave the roadway at the point A, turning on the out-wheel as an axis at the point O, to the radius C, rotating in the direction as shown by the arrow. The wheel in contact with the roadway will tend to slide in the direction of the arrow B, and this wheel will have to afford all the tractive force.

The curves for speed on arcs of circles will hold true in all cases in which the radius of turning is not too short, but the performance as shown in Fig. 14 will defeat all the laws and render the going dangerous, unless it is on "banked" curves, when the in-wheel will tend to stay on the ground, affording some measure of the tractive ability excepting when the speed is higher than that allowed according to the curve of safe speed under such conditions. As a rule, skidding will intervene before the in-wheel will leave the ground, but a rut in the roadway or an obstruction in the way of skidding will introduce an accident.

Bursting Front Wheel Tires Dangerous.—In fast going, it generally happens that the bursting of tires, as in a "blow-out," results in danger to the occupants of the car, because the diameter of the wheel is less after the tire bursts, while the tire on the opposite side remains as before. The result is, a car tends to turn in a circle the axis of which will be of a cone, as shown in Fig. 15, at O. If one of the tires is allowed to come off, the cone will touch the rim of the wheel without a tire at A and A' and the outer wheel, on which the tire will remain, will contact as usual at B and B'. The radius of turning will be such as to introduce a serious hazard even if the speed on the car is not very high, unless the driver prevents the car from turning around on the circle whose axis is at O in Fig. 15, since the radius of the curve might be even below 20 feet, depending upon the sizes of tires used on the wheels.

It is interesting to note, then, anything which will tend to seriously reduce tires to the point likely to cause a "blowout," such as running on car tracks, as shown in Fig. 16. In this case it is plain to be seen that all the ingenuity in the world could not bring on a blowout any quicker. This section of rail is not used in modern streets in which the pavement is good, but it will be found in the sparce districts, just where the rolling may be had, and when the temptation to use the car tracks will be the greatest. In all cases the use of car tracks is to be looked upon as dangerous, even in the cases in which the rails are flat on the tread, for the reason that rails do not always remain in good order, and a knife-edge will soon make short work of the casings.

Tires Should Be Inflated Sufficiently.—In many automobiles the front tires are of smaller section than on the rear, primarily to afford a sufficient turning (canting) angle of the wheels, but there is a second reason bound up in the ease with which the narrow tires will allow the steering wheel to cant the road wheels around. The difficulty in steering is accentuated if the tires are not properly inflated, while the wheels will bounce off of the roadbed if the pressure in the tires is excessive.

While it is true that the rear wheels should be inflated more than the front, because the load to be borne is more, the fact remains that the front tires should be stoutly inflated in order to

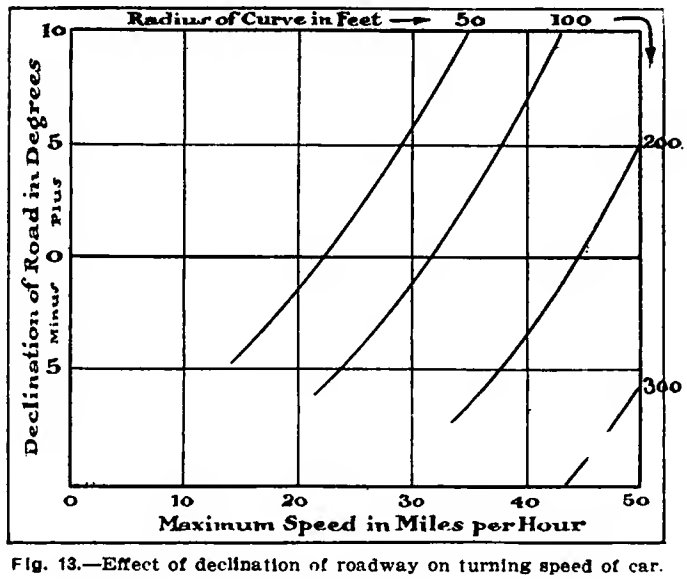

Fig. 13.—Effect of declination of roadway on turning speed of car.

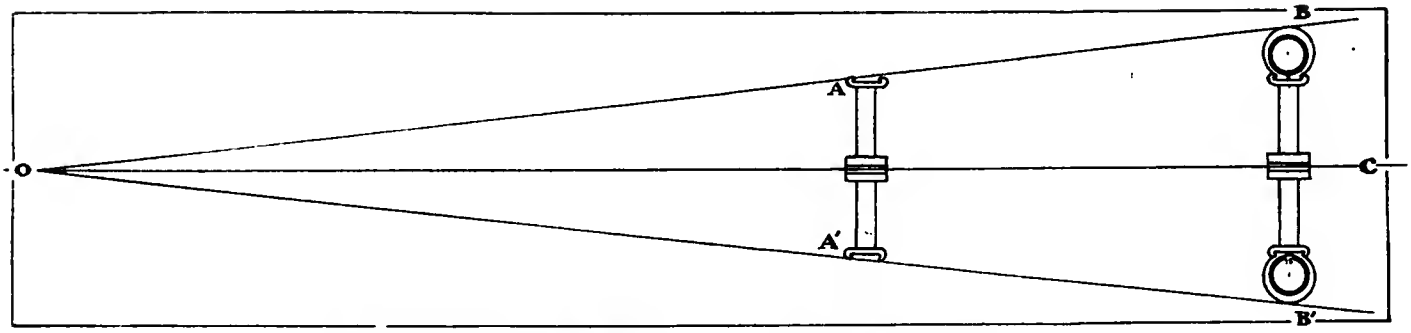

Fig. 15.—Diagram showing how to find turning radius with one tire off.

assure traction on a maximum basis, on the one hand, and to enable the wheel to cant easily on the other. The pressure per square inch at the point of contact of the tires will depend upon the weight on the wheels and the degree of inflation. If the tires are not well inflated they will squash down and the area will increase accordingly. In this case the pressure per square inch under the tires on the roadbed will be low, whereas if the tires are well inflated it is then that the pressure per square inch will increase accordingly, with the result that the adhesion will be augmented, unless it is that the tires are inflated to a point eliminating any tendency to squash.

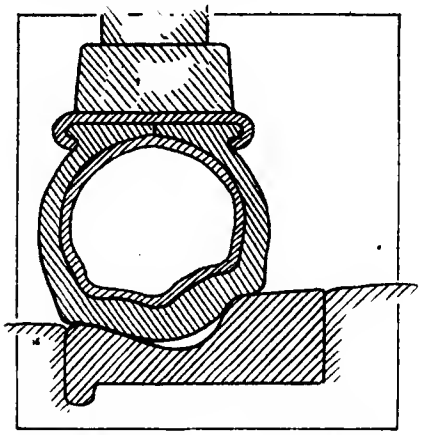

Fig. 16.—Section of tire when deformed by car track of this shape.

The curve, Fig. 17, affords information in relation to the extent to which tires should be inflated considering the best results. In this case air is taken as the medium for the purpose, and it will be worth while to call attention to several details involving the use of other gas media besides air, since the results are not the same in all cases. The curve, Fig. 17, shows that the pressure of the air increases as the tires heat up, as they will under the load, due to molecular work. Some inflating gases are more marked in this phenomenon, and it is important to take this into account.

Diffusion of Gases Depends Upon Composition.—Air will stay in tires longer than any other gas used for the purpose, for the reason that the defusion of air through rubber is at a lower rate than will be that of carbon dioxide or any other gas such as might be used for the purpose, of which the author has knowledge. In some experiments which the author made for the purpose it was found that the ratio of diffusion of air to carbon dioxide was as 12 is to 30, considering the tubes used in the experiment.

If the inflating is done with carbon dioxide it is necessary to take into account the rate of diffusion, and inflate the tires more often, so that the desired pressure will be in the tires at all times. It is at the time when such matters are not attended to that dangers arrive and hazards make bold to proclaim ownership. It is also true that some gases increase in pressure due to heat, more than air. This is a matter for separate treatment.

Should the Front Road Wheels Toe In?—If the front road wheels are not set parallel steering will be affected in some way depending upon the relation of the wheels to each other. If one wheel toes in and the other is parallel with the roadway, it will be very difficult indeed to steer the car, especially if the road is in a slippery condition. If both wheels are set parallel to each other, and parallel to the roadway, steering will be far less difficult, but it will still be far from perfect. One way to overcome the troubles of steering as they come from the set of the front road wheels, is to have both wheels toe in.

The amount of the in-toeing should not exceed 1 degree from the center, for each of the wheels, but it is desirable to have the angle of the two wheels carefully adjusted, so that they will both toe in the same amount. This in-toe will cause slight wearing of the tread of the tires, but it is probable that the wear will not be so much as will follow if the wheels are not so adjusted since in the absence of this set of the wheels they will be more prone to skid, and it is a moral certainty that skidding is the most damaging to the tires of all the happenings on the road, barring a tenpenny wire nail, fastened in a board, with the business end up.

There is one other advantage to follow the set of the front road wheels in the manner as described. It is difficult, if not impossible to keep all lost motion out of the knuckle joints, and as this lost motion increases, it tends to throw the wheels out of the right relation with the road, and with this mal state, steering troubles are increased to a vast extent. In other words, the sag which must follow lost motion in the knuckle joints will cause the wheels to toe out, but there can be no assurance at all that the two wheels will toe out an equal amount. As against this, it is generally conceded that, if there must be a difference in the amount of the toe, it is better to have both wheels toe in, in any case, even if they do not hold to exactly the same angle. If the wheels toe in, and if in slowing down, with a view to coming to a stop, the power is not thrown off, skidding will not follow, even if the roadway is not so very good. The design of gasoline cars does not permit of leaving the power on, but in electric cars it is possible to allow the motor to stay in circuit, exerting some force. It is even possible with planetary gears to take advantage of this fact. A good deal depends upon the acumen of the driver when reference is had to difficult road work, and it is the height of folly for a new driver to trust to his lately acquired experience to guide him through dangerous channels due to speed-made tendencies in the absence of enough experience to assure a fair measure of automatic action.

(To be continued.)

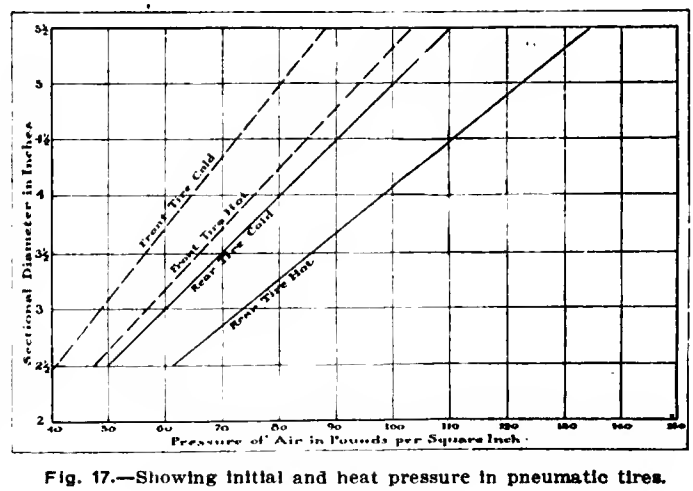

Fig. 17.—Showing initial and heat pressure in pneumatic tires.

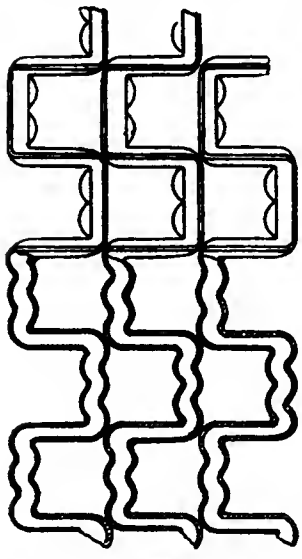
AUTOMOBILE COOLING SYSTEMS ANALYZED

By MORRIS A. HALL.

THE cooling of a gasoline or other automobile engine may seem a simple thing to the uinitiated, but in reality it is far from that and it is a fact that the deeper one goes into it the more complex the situation becomes.

Speaking broadly, the cooling of internal combustion engines, in which category all automobile engines come, is divided into two classes according to whether the cooling medium is a liquid or a gas. This broad classification, when reduced to every-day language, gives us the air and water cooled genera. In the latter case, however, the one mentioned is but a single instance of many. That is, to complete the class, it would be necessary to mention also oil cooling and the use of other fluids. On the other hand, in the class of engines using a gas for the cooling media, the writer has never heard of the use of or any proposal or suggestion to use anything except air.



Method of Increasing Surface.

It will be well at the start to correct a popular notion as to the function of the cooling media. It is the general impression that the office of cooling substances is to abstract the heat from the gases within the cylinder, this heat having been generated by the explosion. The idea, as stated before, is an erroneous one, for, as a matter of fact, the duty of the cooling medium is to keep the cylinder walls cool, and that only. These walls must be kept cool for two reasons: one is to permit of proper lubrication, without which the piston could not move up and down in the cylinder. Lubricants have a definite flash point, and when this temperature is reached they will burn and leave a carbon residue. In other words, then, the cylinder walls must be kept cool to prevent the carbonizing of the lubricating oil.

The second reason for cooling the cylinder walls is to prevent preignition. If the metal be allowed to heat up to red heat, for instance, the fuel will ignite during the compression stroke, previous to the completion of the stroke and thus cause the engine to reverse. Even if not occurring before the end of the stroke, this would cause firing at irregular intervals which could not be predetermined. Consequently, the power would be indeterminate and unreliable.

To go back to the first reason for cooling and the common, erroneous idea of the same, the gases within the cylinders should retain as much as possible of the heat produced by the combustion. Therefore, it is advisable to let the cylinder work at as high a temperature as the lubricating oil will stand without carbonizing. This fact is pertinently brought out by one of the makers of air coolers, who in his catalogue makes the following statement which is quoted verbatim: "The nearer the cylinder temperature of a gas engine can be kept to 350 deg. the better it works and the more efficient it is. In other words, a gas engine does its best work and gets the most power out of the gasoline at a wall temperature of about 350 deg."

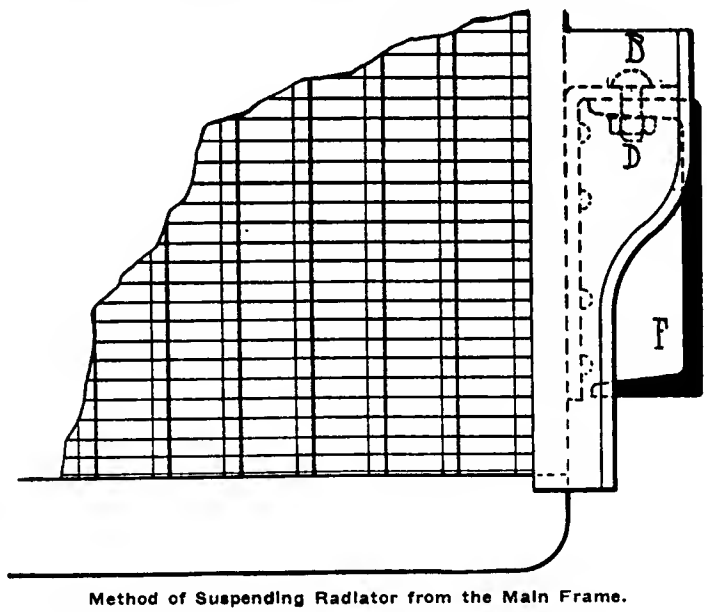
With a temperature as high as this, the thermal efficiency is also very high, but the other side of the question lies concealed within the mechanical efficiency. This has no direct connection with the heat-cycle competence unless it be that it varies inversely with the latter. At any rate, it is certain that with temperatures such as this not only common, but the regular thing, it is certain that a tight or even close-fitting piston is impossible. From this and other details which might be mentioned if space allowed, it is at once apparent that the mechanical efficiency is very low, indeed. The inference then is, to obtain the maximum heat efficiency a large sacrifice of mechanical efficiency must be made. Also, the reverse of this holds, that to get a high mechanical ability, heat efficiency must be sacrificed or a balance struck between the two. This is the course usually pursued.

Reliability the Most Important Factor.—In keeping the cylinder wall temperature high and close to the carbonizing point of the oil, care must be used not to overdo this for, in the last analysis, reliability is the desireratum and by attempting to do too much with the retention of heat within the mixture, this very desirable quantity will be lost. As this is the one factor which held the gasoline engine back for many years, it would be a serious matter to lose it now. This is a factor which the advocates of the simpler gas-cooling systems, in their reaching after simplicity, have lost sight of.

A point easily seen to be in favor of the more bulky, assuredly heavier and admittedly more complicated fluid systems with positive circulation, at once crops out in the light of what has been said above. This, put into words, is that regardless of bulk, weight and complication this, as exemplified by the pump circulated water system, is both reliable and consistent. The ratio of cooling substance to power which upon analysis is seen to be the desired quantity, is here obtained and here only. The positive assurance of this regular, unswerving ratio is worth a great deal and it is a question if it is not worth more than all the extra weight, bulk, etc.

The Relation of the Structure to the Efficiency.—While the bare statement that the structure, or to be more explicit, the design, has a positive relation to the efficiency and a direct bearing upon the results, is at first sight a strong one, the facts, upon close scrutiny, bear it out. It will not be denied that the temperature of the explosion, which is the influencing factor in the efficiency formula, is governed by the temperature of compression. This, in turn, is wholly dependant upon the pressure of compression, which is a fixed portion of the structure, or, in other words, is a predetermined part of the design.

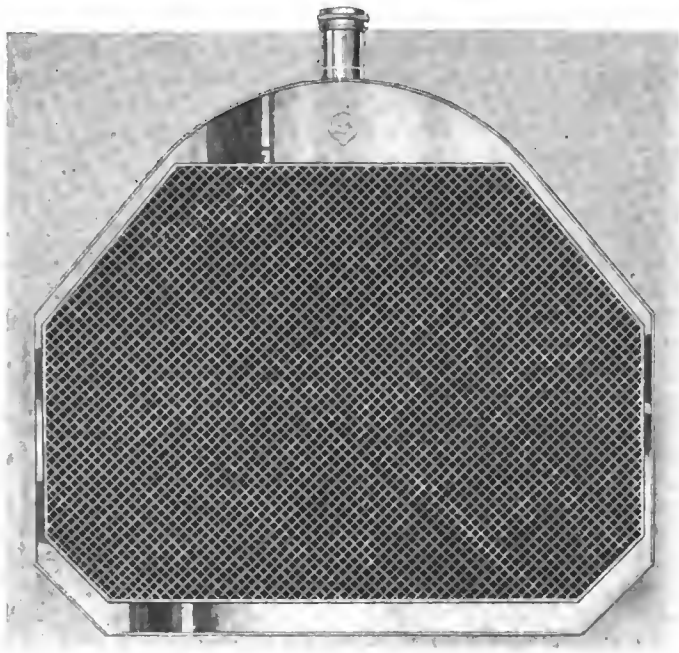
The effect of a high compression then is to increase the efficiency of the heat cycle. This may be done by reducing the size of the compression chamber and by increasing the stroke or otherwise. It is at once apparent that any increase in the initial temperature means a proportionate increase in the heat which



Method of Suspending Radiator from the Main Frame.

must be carried away and in the case of the decreased combustion chamber the difficulty of doing this is increased at the same time. From this it is obvious that an increase in efficency must not be sought blindly else the results will not be satisfactory. An alternative method is to obtain the desired result by increasing the speed. With the gas-cooled method this is practically impossible, but for the liquid-cooling system, in which positive circulation is utilized, this is an excellent way, as with increased speed of the motor, comes increased speed of the cooling medium because the means of propagation bear a fixed ratio to the speed of the engine.

Heat Balance Expressed in Percentages.—To express the heat balance in a reasonable and easily understood manner, let us give it in proportion of the total heat, or in other words, in percentages of the possible heat which the gas is capable of producing. According to one well-known authority, whose figures on this subject have never been disproven and are therefore reliable, the average distribution of the heat energy of the fuel is:



A Neat Example of the So-called Mercedes Type.

TABLE 1.

Useful Work	17 per cent.
Loss to the Exhaust	16 per cent.
Carried off by Jacket Water	52 per cent.
Radiation, Conductton, etc	15 per cent.
Total	100 per cent.

This means, then, that of the total energy which the gas develops in the cylinder, only 17 per cent. goes to useful work as it results in speed, hill-climbing or other manifestations of ability. The other 83 per cent. is wasted in various ways, by far the largest and most important of which is the one we are here concerned with, the heat carried through the cylinder walls and then carried away by the cooling medium, 52 per cent. of the whole, as shown above.

Now to go deeper into this distribution of heat and in particular, into the amount carried by the jacket water, it will be necessary to go into the mathematics and give a few formulæ.

(1) 1 Horsepower = 33,000 foot-pounds per minute.

(2) 1 B.T.U. = 778 foot-pounds.

From the above, to reduce mechanical power to heat units, usually abbreviated B.T.U.,

$$(3)\quad \frac{\text{H.P.} \times 33{,}000}{778} = 42.42 \times \text{H.P.} = \text{B.T.U. per minute.}$$

This mechanical equivalent of power expressed in heat units may be put in the more convenient form of units per hour by simply multiplying by sixty, or,

$$(4)\quad 2{,}545.2 \times \text{H.P.} = \text{B.T.U. per hour.}$$

Figures for a Selected Example.—If a 20-horsepower (20 H.P.) engine be selected to apply these figures to, multiplication by 20 gives the heat equivalent of this power as 50,904 B.T.U. per hour. The mechanical efficiency of the engine must be taken into account here so that a factor allowing for this loss must be introduced. This has been known to reach a figure of 90 per cent. or .90, but in calculations of this nature .80 is commonly used. Moreover, from this, the total heat content of the fuel is found by figuring backward from the resultant heat and the proportion of the whole as given above in Table 1, thus:

$$(5)\quad \frac{20 \times 2{,}545.2}{.90 \times .17} = 332{,}300 \text{ total B.T.U. in fuel.}$$

From this total the corresponding figures for the other divisions are readily obtained. These are:

TABLE 2.

Division.	Percent.	Heat-units.	Equiv. H.P.
Useful Work	17	56,300	22.2
Exhaust Loss	16	53,000	20.9
Jacket Water	52	173,000	68.0
Other Losses	15	50,000	19.6
Totals	100	332,300	130.7

It is then apparent that the losses are enormous, for, to get an actual delivered horsepower of 20, it is necessary to deliver a fuel with a latent content of over 130 horsepower. Of this, the extra 110 is not only unavoidable, but also absolutely necessary from the "nature of the beast," so to speak.

Jacket Water or Other Cooling Medium Carries Most of the Heat.—To return to the subject under discussion, the cooling medium, it is at once apparent that this must carry off an enormous percentage of the total loss. In the above typical case the amount to be disposed of in this manner is no less than 173,000 B.T.U. per hour. To carry through a rough calculation of the amount of fluid necessary to conduct this away let water be assumed as the medium, also let it be assumed that one B.T.U. is the heat necessary to raise 1 pound of water 1 deg., which is not absolutely correct, but simplifies the calculations. Then in a hypothetical case, the water is put in at 100 deg. and taken out at 200 deg., a rise of 100. Then to carry off 173,000 B.T.U. per hour will require

$$(6)\quad \frac{173{,}000}{100} = 1{,}730 \text{ lb. of water per hour} = 182 \text{ gal. per hr.}$$

In all fairness, it must be added that these figures are far from the actual. The water will seldom be allowed to reach 200 deg. for in some regions that would be boiling, and the lower limit seldom gets down to 100 for average continuous running. A more fair estimate, then, would just about double the above figures, which were chosen at random to show the method of figuring. The resultant figure is, then, 364 gallons per hour. Reducing this to amount per horsepower, to show the relative quantity to be used:

$$(7)\quad \frac{364}{20} = 18.2 \text{ gals. per H.P. per hour.}$$

This is an approximation, of course, for the mechanical efficiency was assumed, and if taken too high, lowering it would raise the total heat, and with it the heat of the jacket. The increase in the latter will increase the weight or quantity of the cooling water, so it is usual to select such a figure as will give an excess. This is not allowed to keep the cylinders cold, but is circulated slower to compensate for the excess quantity. It is in this connection that the type and mechanical efficiency of the pump used enter into the problem.

(To be continued.)

HOW THE NOVICE GETS HIS INSTRUCTION

SPECIALIZATION in automobile instruction to meet the needs of owners and prospective owners of special types of cars is the latest improvement introduced into its course of study by the automobile school of the West Side Young Men's Christian Association of New York City. Under this plan, while every pupil is given a thorough course in general automobile operation and repair designed to fit a man to be chauffeur of any type of machine, an owner who wishes to become absolute master of his own car, as well as the possessor of it, may elect to have special instruction which will train him to get the maximum road results out of his car and also to make on the road all ordinary repairs not requiring a machine shop.

That the new plan is decidedly popular is evidenced by the fact that when the school opened for the January term of 1909, a class of 100 students was enrolled, two of whom came from as far as Mississippi and another from Canada to enter.

The plan as outlined would require the services of far more cars than could either be purchased or borrowed, while it would be impracticable to try to get a car just for the occasion from the New York agents when an owner of that make turned up. Inasmuch as the entire fees charged are used to increase the general Y. M. C. A. revenues, it was equally impossible to purchase the various machines.

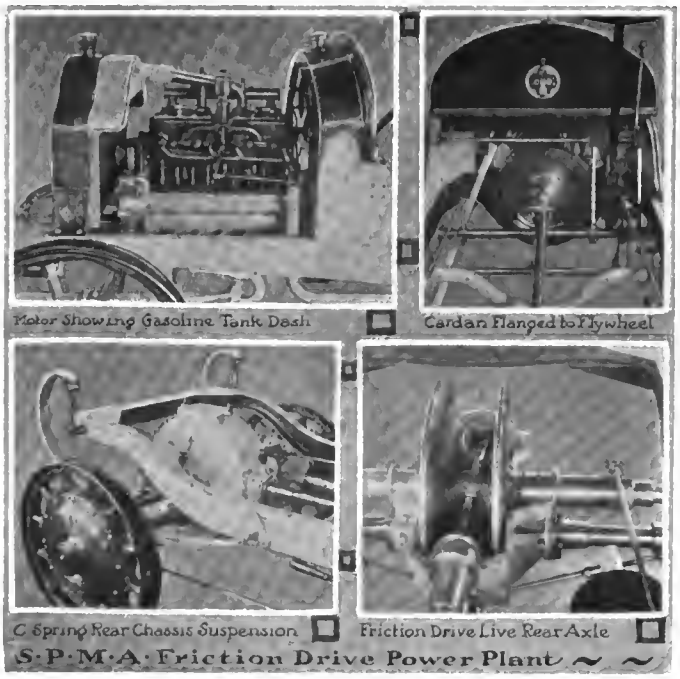
A number of the manufacturers, realizing the part which this non-commercial school plays in the development of automobiling by training men thoroughly and at a moderate fee, are aiding the officers of the Y. M. C. A. school by donations of cars and models. The Haynes company has recently given a fully equipped four-cylinder touring car, the Ford interests have promised to do likewise, and other makers have accepted the Association's invitations to inspect its work and have shown their interest by donating equipment.

Makers of automobile accessories have also appreciated the value of a good, reliable course of instruction and have aided in the effort to establish an experimental and practical laboratory of automobile devices where its present and former students, numbering nearly 3,000, can study and work with new inventions or types of construction. The gift of Eisemann magnetos from Lavalette & Co., of New York, and a 7-horsepower gas engine from the Bridgeport Motor Company has been much appreciated by the students.

The same plan of instruction that has been followed in the past will be continued this year in all classes of instruction, that of giving all students a thorough mechanical knowledge of motors, and other parts of the chassis in the shops before they are taken out upon the roads. When they are well able to care for a car in case of road trouble competent instructors, one teacher to each student, will take cars out and give lessons in road and street operation, both in the country and on city streets, where traffic practice can be obtained.

A great deal of interest in the conduct of the courses was shown at the Grand Central Palace show, where a booth was donated by the management, and it was there that the attention of certain manufacturers was secured. It has been discovered by some makers that the courses given frequently lead to sales, principally because of the makes of cars used in instruction, a fact that occurs simply because the Association was fortunate in securing these.

The election to the advisory board of the school of Alfred Reeves, general manager of the American Motor Car Manufacturers' Association, has been pleasing to school's friends.



JUST OUT OF THE SHOPS ABROAD

By W. F. Bradley

PARIS, March 3.—Friction-driven cars are not a French feature, there being but one firm, to our knowledge, having devoted attention to a type of vehicle so well known in the States. There is a newcomer in the field, however, who has produced a friction-driven car on new and original lines. Robert Dubois, the inventor of the S. P. M. A. automobile, a Parisian production, carries his classical four-cylinder engine forward under a bonnet, has a universal behind the flywheel, and proceeds direct to the rear axle by one long propeller shaft squared for its entire length. Mounted near the extremity of the shaft is a solid-steel drum which can be moved backward and forward in the same way as a sliding-gear set, and by exactly the same means, namely, a side lever and notched sector. The shaft passes completely through the rear axle housing, and is carried in large bearing at each end. Within the housing, and flanking the steel drum on the propeller shaft, are two friction plates bolted to the extremity of each of the two halves of the live axle. The necessary friction is obtained by means of coil springs contained within the axle casing, and contracted by an eccentric with connecting bars linking up to the clutch pedal. As will be readily seen, the operation of gear changing is, so far as the driver is concerned, the same as on nine-tenths of modern cars: depression of the clutch pedal, with the consequential separating of the two disks, and, by means of the side lever, the shifting of the driving drum along its shaft so that it will come in contact with a different horizontal diameter of the friction pulleys. The operation is the same as the one on cars with sliding gears with the advantage of not requiring any skill to cause the gears to mesh.

There are five forward speeds, one reverse, and of course a neutral position. This latter is obtained by bringing the driving drum in the horizontal line of the driving axles, which, being hollow at this point, leave nothing for the drum to work upon. Advantages claimed for the system are increased frictional surface, and, in consequence, decreased loss of power; also added simplicity by reason of a backward and forward movement of the driving pulley only, without any need for the pivoting shaft generally used on friction-driven cars. The friction plates are contained in an aluminum housing, which has the appearance of an unnecessarily large differential housing. It has inspection plates at the top and at the rear, and in addition the upper half of the housing can be removed in one unit by the withdrawal of a few bolts.

The objection will at once be raised that a drum mounted on the end of the propeller shaft and driving friction disks to left and right of it will turn the road wheels in opposite directions. Obviously such would be the case if provision were not made to avoid it. The weight of the car is carried on dead axles, the drive being through the live axles, the inner end of each one carrying the friction pulley and the outer end a pinion meshing with an internal gear contained within enclosed drums on the road wheels. With such a system it is a simple matter to interpose a pinion which will transform the reverse movement into a forward one with the same gearing as that of the opposite directly driven wheel.

And the differential? it will be asked. There is none. Theoretically, with the coil springs in proper condition, the two which should be driven at the same rate, and turning should be a difficult matter at speed. In practice, however, it is found that such is not the case, and although the inventor is not in a position to explain why it is so, the fact remains that there is sufficient slip on the plate connected up to the wheel on the inside of the curve to allow any turn to be made at high speed with the same ease as on a differential car. As a proof of its ability to pull under a load and on a heavy grade the car was taken to the top of Montmartre, where, on a 13-per-cent. grade that rarely sees any vehicle, several stops and starts were made with full complement of passengers on board. The car making the demonstration had been in constant use for twelve months. Some portion of the success of the car in this respect is undoubtedly due to the metals employed for the driving drum and the friction disks, the nature of which it is not desired to make public at present.

A reduction of weight is obviously one of the greatest advantages of this system, for at one end of the chassis is an ordinary engine, and at the other a rear axle weighing less than the same organ on the average shaft-driven car. Between the two is a propeller shaft and four steel ties, connecting up to the brakes and the springs. The total weight of the chassis, in complete condition is declared to be 1,210 pounds. The engine has a bore of 75 and a stroke of 110 millimeters, which gives a nominal rating of 14 horsepower. There has been no attempt to depart from standard lines of construction. A detail feature, however, is that petrol and oil tanks are on the forward face of the dashboard, the only thing in connection with the running of the engine that is to the rear of the dashboard being a single sightfeed and switch combined.

Suspension at the front is by semi-elliptics, but at the rear a special type of C spring is employed, the feature of which is that the tension can be altered with a few turns of a wrench in order to suit heavy or light bodies.

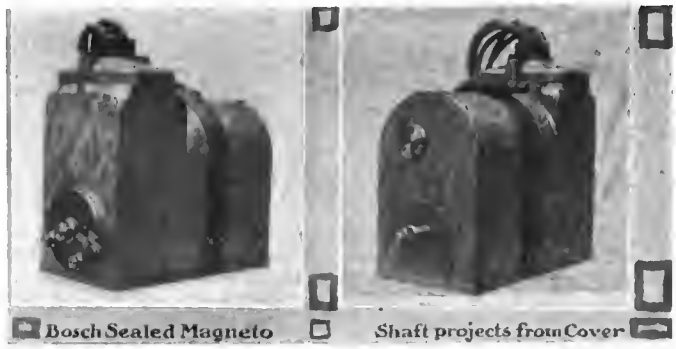
A NEW WATERPROOF MAGNETO COVER.

PARIS, March 10.—Little attention has been paid to the protection of the magnetic machine which supplies the indispensable spark to the cylinders of an automobile engine. The car bonnet is generally considered sufficient to keep off the worst enemy—wet; but the inadequacy of this is shown by the number of careful drivers who during the wet season cover the bonnet with an efficient waterproof. For marine work some protection is absolutely necessary, especially on racing craft, that necessarily ship a certain amount of water at high speeds, some of which finds its way into the engine room. More than one breakdown at Monaco has been due to no other cause whatever than the magneto receiving a drenching from flying spray.

This drawback has been entirely removed by the Bosch company by the recent production of a metal magneto cover, which is guaranteed to be absolutely waterproof. There is nothing

in common with this cover and the canvas and rubber ones which have been put on the market, which certainly protected the magneto from flying spray, but were powerless to prevent the penetration of water if poured on in a volume. It is a hammered brass case which is employed, with but a single welded seam. The case fits closely onto the magneto platform, which is provided with a raised waterproof beading, the only projections being the driving shaft at one end and the timing lever at the other. The encircling metal band securing the magneto to its platform is here on the outside of the case, and is secured in the usual way, as will be seen from the illustration.

A separate cover is provided for the contact plugs, this being bolted down to the main portion of the casing. The insulated leads all pass to the inside of the cover through one opening, which has also been made watertight. As oil holes are provided on the casing, it should never be necessary to dismount this latter except when it is required to entirely dismount the magneto. The firing of the cylinders can be verified by withdrawing the two bolts holding the cap in position, and without in any way interfering with the general body of the magneto. As this verification is far from being a daily occurrence, automobilists will not object to the removal of two bolts when it becomes necessary. The advantages of such a cover are so obvious that it is safe to predict its general use not only for open motor boats, but on all well-equipped cars.



Bosch Sealed Magneto — Shaft projects from Cover

FEATURES OF NEW AIR PROPELLER BRAKE.

PARIS, March 10.—Braking generally consists of the friction of a moving part on a fixed portion of the machinery, a system that has in its favor simplicity and ease of application, and general efficiency where the braking effort is intermittent. Where the retarding influence has to be continued without intermission for a long period, as often happens on good surface mountain roads, the friction sets up so much heat that the brake rapidly becomes inefficient. It was the development of automobiling on perfect European mountain roads, with grades of five to ten per cent. for several miles, that drew attention to water-cooled brakes, now so common on big cars, and the use of the engine as a retarder.

A device has just been produced by the Peugeot firm by which an aerial propeller carried under the car is made to retard the vehicle without any possibility of heating and consequent inefficiency through prolonged application. The propeller, composed of two flat steel blades, is mounted at the end of a vertical shaft, the housing of which is attached to one of the cross members of the frame to the rear of the engine. The housing is stiffened by stout rods passing from its base to another cross-frame member further in the rear. The Peugeot truck on which this system has been fitted has a final drive by double side chains, the gearset being combined with the differential on the countershaft. From the gearset a horizontal propeller shaft is carried forward and attacks the vertical propeller shaft by means of bevel gearing. Thus, on the vehicle being in motion, the aerial propeller is driven from the road wheels through the gearset and the propeller shaft. Provision is, of course, made for engaging or disengaging the propeller at will by means of a special lever on the dashboard. The gearset through which the car is driven is employed for driving the propeller, which, of course, profits by the different ratios, the driver being able to increase or decrease the speed of the propeller in relation to that of the vehicle by a simple change of gear. With the propeller running on its high gear a very powerful retarding influence is created as the result of the resistance of the air on the revolving blades.

A test of the system was recently made from the top of Mont Valerien, a hill overlooking Paris to the banks of the river Seine. The engine was stopped and the vehicle, a commercial truck with a load of 3 1-2 tons, was allowed to run down. The total distance of about two miles was covered at a speed of slightly less than three miles an hour, without the driver on any occasion touching his ordinary set of brakes. It is intended to continue the experiments and produce a model in which the propeller, instead of obtaining its resistance from the air, will revolve in a liquid, either water or glycerine. At present the brake is only applied to the company's heavy commercial vehicles, but will doubtless be fitted later to the larger touring cars. There is one other advantage to be taken into account in connection with brakes which receive their "purchase" by way of opposition in the air—*i.e.*, it does not matter at all if the wheels lose their tractive ability, since the "fan" brakes would still be in a position to work, regardless of the tractive ability of the road wheels. Indeed, the car, fitted out in this fashion, could be controlled even if the wheels might slip, so that the conventional brakes would fail to work, due to loss of traction on a grade.

Peugeot Air Propeller Brakes Under Car

Lever Control for Peugeot Brake

Letters Interesting and Instructive

SOME QUERIES AS TO VARIOUS RECORDS.

Editor THE AUTOMOBILE:

[1,790.]—Will you kindly answer the following questions for me:

1. What automobile, either steam or gasoline, has the fastest record for one, two, five, ten and twenty-five miles?

2. Has the White Company ever built a car with more than 30-horsepower until this year? If so, when and where?

3. Has the White steamer ever been defeated in any hill climb? If so, by what car and what was the time and distance?

4. What is the record of the Buick car for one, two and five miles? FRED T. TREMBLE.

Saranac Lake, N. Y.

1. The following records for 1, 2, 5 and 10 miles were made in 1906, on the beach at Ormond, Florida: One mile—Marriott, Stanley steamer, 0:28 1-5; two miles—Demogeot, 200-horsepower Darracq, 0:58 2-5; five miles—Hemery, 200-horsepower Darracq, 2:34; ten miles—MacDonald, 90-horsepower Napier, 6:15. The record for 25 miles is that made on the Fresno track by Barney Oldfield, in a 60-horsepower Peerless, and is 23:38 3-5. The straightaway record for that distance is not listed.

2. The White Company has never built a stock model of more than 30-horsepower until this year.

3. Your question is too general and the field too great to allow of our giving an accurate answer.

4. It would probably be advisable to communicate with the manufacturers of this car to secure a satisfactory answer.

THE CARE OF AN AUTOMOBILE BODY.

Editor THE AUTOMOBILE:

[1,791.]—Please be good enough to answer in your "Letters Interesting and Instructive" the following: In the summer time the body of a car is oftentimes merely dusty, and a good dust-off would make it look as good as ever, if only you could pick the dust off clean, but a dry duster, although picking up the most, still spreads a certain amount, making it necessary to go all over again with another cloth to make a perfect job. Is there not some simple thing that I can dampen my cloth with that will pick the dust up clean, not hurt the finish, nor leave it greasy or sticky? J. D.

Portland, Ore.

A highly finished body should never be wiped off dry, as it is impossible to do this and not scratch the polished surface. The best and quickest way is to turn a hose on it and then while still wet wipe off with a piece of chamois or a soft cloth. Waste might be used if of a selected grade, but the ordinary cheap kind must never be utilized, as it contains small sticks and other hard substances which will scratch the varnish. There are many cleaning substances now made, and by consulting the advertising pages of THE AUTOMOBILE you will doubtless find one that will suit you.

THE RECORD TIME ON A STRAIGHTAWAY.

Editor THE AUTOMOBILE:

[1,792.]—Kindly tell me in "Letters Interesting and Instructive" the greatest speed ever maintained by an automobile on a straightaway and also the name of the car. L. E. HOWE.

Liberty, Ind.

The greatest speed ever attained by an automobile on a straightaway was made at Ormond Beach, Fla., on Jan. 26, 1906, by Fred Marriott, driving a Stanley steamer. On this occasion he did the mile in 28 1-5 seconds and the kilometer in 18 2-5 seconds. The former is at the rate of 127.6 miles per hour, and the latter 121.6 miles per hour. At this same place and on the same day Louis Chevrolet, driving a 200-horsepower Darracq, made the fastest times for a gasoline machine on a straightaway. He covered the mile in 30 3-5 seconds and the kilometer in 19 2-5 seconds, which is 117.6 miles per hour and 115.3 miles per hour, respectively. Four days later, driving the same car, Demogeot drove two miles in 58 2-5, at the rate of 123.3 m.p.h.

ENGINE PERSISTS IN OVERHEATING.

Editor THE AUTOMOBILE:

[1,793.]—Having observed in your issue of February 4 a letter signed P. O. Peterson, in which he complains of his air-cooled car at times running hot, and your reply to same, would say I ran an air-cooled car of popular make (1906 model) for two years with fair satisfaction, sufficient to warrant the purchase of a 1908 model of same make last Summer. This car has proved unsatisfactory as it has been impossible to run it on even moderately warm days without constant overheating of the engine. As I ran an air-cooled car successfully for two years, I feel certain this is no case of retarded spark, lack of adequate supply of a suitable grade of lubricating oil, or of too rich a mixture, and if Mr. Peterson's car is of the same model as mine, probably nothing short of a more powerful engine capable of carrying a fan will suffice to keep his motor cool on warm days. DR. C. N. CUTLER.

Chelsea, Mass.

Your engine is powerful enough to run a fan, as very little power is consumed in this manner, but that is not your trouble. It appears from the symptoms that your valves may not be correctly timed so as to exhaust at the proper time, for instance. Again, there is the bare possibility that you have an unusually stiff set of piston rings, which are absorbing lots of power. After you have fitted a fan, if it does not relieve the situation, you might follow up these suggestions. If you had not previously driven an air-cooler, we would make the suggestion that the makers of these recommend a hot running condition, the Franklin Company, for instance, recommending 350 degrees.

BEARING METAL IN AUTOMOBILE MOTORS.

Editor THE AUTOMOBILE:

[1,794.]—Can you tell me what kind of metal is used in the large ends of the connecting rod bearings in so many automobile engines? I have melted some of the scrap metal and it melts in a ladle like babbitt, but at somewhat higher heat and after poured requires longer to chill and harden than babbitt metal does. If you can tell me what this metal is and where I can obtain it, it will be appreciated. J. D. F.

East McKeesport, Pa.

In many cases the metal used is of the copper-tin alloy in which the tin content is 90 per cent. This metal is quite hard, melts at a high temperature, relatively, and requires some skill in the fabricating process. In its use the results are not always good for the reason that the "teeming" is done at too low a temperature. In pouring this metal in the process of fashioning bearings it is necessary to raise the metal to a red heat. It should be covered with charcoal to keep it from oxidizing.

In some cases it is the practice to take a good grade of babbitt, such as can be had on the open market, and after melting the same in a pot, it is loaded with tin until a specimen, after it solidifies, will fracture readily, showing a cold-short condition. Very good results have been realized in this way, although it is true that the copper-tin metal as previously discussed has the advantage of being the more certain.

A GOOD CHANCE FOR GENIUS TO CLIMB.

Editor THE AUTOMOBILE:

[1,795.]—I would like to be informed through the columns of "The Automobile," or otherwise, whether there is any signal code in use among the best autoists in the country, whereby one automobile driver can inform another by the use of his horn whether he is going to stop, or start, or turn to the right or to the left, etc. Also please tell me what is the proper use of the horn in saluting other machines if you chance to meet one on the road. If there is no signal code for the purposes that I have mentioned, could not the one used by steamboats on the ocean be used for this purpose, with perhaps a few alterations, and if so, will you have the kindness to tell me what that is. There does not seem to be any rule for the use of the horn around here; they all toot away one, two or three blasts. That seems to mean, if they mean anything, look out or get

out, or something of that kind. I am going ahead, or going to stop, or going to turn to the right or to the left, or turn around, or do any other old thing that comes into my head to do. I am satisfied from my own experience that the knowledge and use of a signal code would prevent many accidsnts and do away with much inconvenience, not only to pedestrians, but to horse drivers as well, who would soon learn the meaning of thess signals if they were in common use. For instance, I am driving down a road that crosses another road and I want to turn into the left hand road at the point of the crossing. I, of course, slow up in order to make the turn safely, when another machine that has been following me rather closely, but unobserved by me, seeing me slow up, understands it to mean that I give them an invitation to pass me and they make a dash to do so, and before they find out their mistake a collision results. A SUBSCRIBER.

Columbus, Ga.

There are no very well understood signals in use; it would be a good chance for you to exercise your talents. The pages of THE AUTOMOBILE will be open to your suggestions.

ELECTRICAL INVENTION SEEMS IMPOSSIBLE.

Editor THE AUTOMOBILE:

[1,796.]—Being much interested in an article entitled "Here's Another Wonderful Invention," on page 322 of your issue of February 18, I wrote the firm named J. W. York & Son, and was greatly surprised to receivs in return my letter of inquiry (which I enclose) upon which was written, "we know nothing in regard to the above."

The invsntion is so utterly opposed to modern knowledge of the generation of electric currents that it has awakened a great deal of interest, and the fact alone of its appsaring in your columns gave it greater prominence, and stamped it with greater reliability than would have been the case had it appeared in some other journals more inclined to the ssnsational. Your valued paper would confer a favor upon its readers if it would give the corrsct names of ths parties directly interested, and any further information it can secure in relation to the matter.

New York City. A. D. WELCH.

One more look at the item as it appeared in THE AUTOMOBILE will disclose to you the fact that it was not regarded as likely to be true. The item came is as "news" and was given space more by way of showing odd slants of the human mind than anything else.

MAXIM'S SILENCER IS A MUFFLER.

Editor THE AUTOMOBILE:

[1,797.]—Maxim's noiseless gun is exciting much interest from a military standpoint.

1. Do you believe this principle could be applied as a muffler of an automobile?
2. If so, would it eliminate back pressure, or would it cause back pressure?
3. Would ths possibility of muffler explosions be eliminatsd?

Tiffin, O. L. O. R.

The principle of the "silencer" is that represented in the muffler as used in automobile work. Back-pressure will follow if the principle is not rightly applied. "Muffler shots" are due to missing in the firing of the charge in one or more of the cylinders. If timing is right, and if the iginition is adequate, provided the mixture is homogenous, and in the right proportion of fuel to air, there should be no trouble of this sort.

GREATEST NUMBER OF AUTOMOBILES.

Editor THE AUTOMOBILE:

[1,798.]—Will you tell me, to settle an argument, what city or town has the greatest percentags of automobiles relative to its population and what that percentage is? Thanking you for the trouble, C. Q. D.

Tekonsha, Mich.

The information necessary to answer your question is not available; in fact, we have never seen or heard of anything of the sort. We can, however, give you a few of the places which have claimed this honor. These are: Waukesha, Wis., one in 220; Decatur, Ill., 170 machines for 30,000 people, which is one in 176; Hart, Mich., 35 for 1,600, that is one in 45, and Tahoka, Tex., with 14 among 500 people. This latter is one automobile for every 35.6 population. London, the largest city in the world, with over 4,500,000 population, has the tremendous total of 40,000 cars, bringing the average there up to one for each 112 people.

MIXED BEVERAGES FOR THE MOTOR.

Editor THE AUTOMOBILE:

[1,799.]—Do you recommend the practice of mixing lubricating oil with gasoline for the purpose of assisting in lubrication of cylinders, pistons, valves, etc., in conjunction with the splash system; and if so, in what proportions should the oil and gasoline be mixed?

Does this practice not interfere with carburetion?

Philadelphia, Pa. J. R. K.

The views of a "pioneer" will be found in this week's letters in relation to this matter. Perhaps others will come forward with a quota rather with the expectation that the scheme will be put on a stable footing.

ABSORPTION DYNAMOMETERS IN DEMAND.

Editor THE AUTOMOBILE:

[1,800.]—We will appreciate it if you will put us in touch with the makers of water absorption dynamometers.

Hope Valley, R. I. N. & L. M. CO.

Several inquiries of a like character would seem to indicate that there is quite some activity in this line. Makers of this class of dynamometers can have information forwarded to the interested parties by addressing the same to this letter number, care THE AUTOMOBILE.

SOME REFLECTIONS OF A PIONEER.

Editor THE AUTOMOBILE:

[1,801.]—Your reply to Mr. Hawkins in the February 11th issue regarding the use of gasoline and lubricating oil mixed, seems to me as likely to do injustice to a splendid method of lubrication.

While, as you state, a mixture of gasoline with oil is not considered a lubricant, it is a fact that ths gasoline is a splendid vshicle for carrying the oil to the place where needed in ths proper quantity and at the proper rate. Mr. Hawkins has used it tsmporarily and regards it as a makeshift, but many people are uisng it regularly. Hoisman oils his latest design of four-cycle engine that way, which he can well do, because, in this case, he draws the mixture into the crank case, and so brings the oil into contact with the parts to be oiled, just as is done in the Duryea buggyaut two-cycle engine, and in many othsrs of this type. The cycls of the engine does make a difference, for in the usual form of four-cycle engine the mixture does not get into the crank case, and so will not oil the parts there.

An amount of oil in the proportion of one to twenty, or, even one to forty, is mixed with the gasoline, and dissolves fully therein, so that the mixture flows through chamois and through the carburetor, just as does gasoline alone. The gasoline evaporates and leaves the oil floating as an exceedingly fine mist. This deposits on all the parts that it comes in contact with and lubricates just as well as if deposited by some other means. Such of it as does not deposit (which I believe to be very little) goes into the cylinders and burns in the intenss heat of the explosion. The deposit on ths spark plug and heads of the cylinders seems to be less by this method of oiling than by the mors common msthods. The quantity of oil required is not excessive. In fact, I consider it less than most methods require. If the engine backfires into the case, the mist of oil is burnsd and the piston fails to be oiled. This is a fault, but the feeding of oil when wanted, and in quantities proportionate to the work done, is such a good feature that ws can afford to fight the one fault hy scrcening the transfer passage so the engine will not backfire.

Everybody admits ths advantage of simplicity and the substitution of this simple method for the usual complicated positive oilers, with better results, is certainly a move in ths right direction, and not to be considered a "makeshift method." It must be remsmbered that the gasoline does not do the lubricating by this method any more than it does when the explosivs charge is admitted into the crankcase with soms other method of feeding. In a number of instances the oil is dropped into the supply pipe, but this renders it necessary to bother with ths adjustment of the oiler, and is not so good a method. A drip oiler feeds in proportion to the time, and does not take account of the revolutions or of ths work done. A pump oiler feeds in proportion to the number of revolutions, hut ths solution method feeds in proportion to the power produced, whether this is in hard pulling at slow speeds with full throttle, or in light work, but with engine racing. It does away with worries about filling the oiler, for one mixes the oil with the gasoline when his supply tank at the garage is filled, and thereafter the filling of the fuel tank of the vehicle takes care of the oiling. It may interest users of the four-cycle engine to know that a little oil with the gasoline will often improve the running of their engines. It lubricates the cylinder walls at the top of the stroke where they are too often dry, and so adds to smooth running, noiselessness, and increases power.

Reading, Pa. CHAS. E. DURYEA.

INDELIBLE EARMARKS OF THE 1909 RENAULT

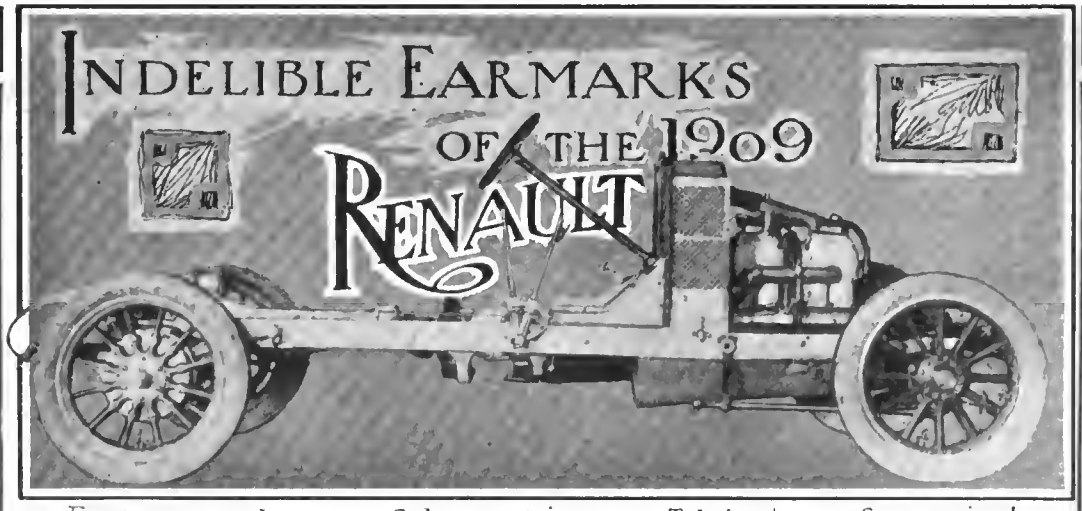


Figure 1 — Chassis Thirty Special

SOME years ago when the utility of the automobile was very much in question, and when the foreign makers of cars made bold to proclaim the qualities of "continental" handiwork, Renault Frères, cantered across, as an early bird, in quest of the worm, bringing along the "Renault"; then, as now, a car to be picked out of a parkful. It is just this detail which has done much to make the Renault car popular, among the buyers of the better class of automobiles. The car has the Renault earmarks, and they are indelible in stability and style of design.

Then, as an importer of automobiles the Renault Frères selling Branch, located at 1776 Broadway, New York City, considered well the American methods, which are so necessary to continued success in this country, and American roads, which are but slightly improved in many places, hence demanding the utmost rigidity of the component parts of cars, coupled with a flexibility of the units, such as can only follow if the design is keen, and if the material is superior.

While it is true that the Renault holds to a certain characteristic design, it is also true that the car has kept pace with time, as experience showed the way to superior materials, and more lucid details in point of design. The Renault, for 1909, embodies all the features, free from frills, such as can be looked upon as fitting in the culmination of the automobile, in view of half a decade of activity of the most strenuous order.

All Alike in the Main Characteristics.—Since all Renault models, of which there are some 17, are as like as peas in a pod, in all the main essentials, it is just possible that the discussion here will be the more comprehensive if it is somewhat restrained, and with this end in view reference may be had to the chassis, Fig. 1, showing to good advantage the general arrangement of the cars, in which the motor is of the four-cylinder type, with vertical cylinders, and the motor is located in the front of the chassis. The power is transmitted by means of a cone clutch, leather faced, to a semi-progressive transmission gearset, with three and four speeds forward, depending upon the model, not counting the reverse. From the gearset the power is transmitted through a propeller shaft to the live rear axle, thence to the rear road wheels.

Likewise, the chassis, in all the models, holds to a common Renault practice, taking into account frames of the channel section of a "super" grade of steel, and with dimensions of the section, such as will afford the requisite degree of rigidity. The frame is of the "drop" type, on certain models, which lowers the center of gravity and makes the side entrance easy, and the spring suspension is with 3-4 elliptic rear members of nice design, while the front springs are half-elliptic, designed for level platform work despite road inequalities of moment.

In this spring suspension account was taken of the constant load in front and the variable nature of the load in the rear, hence the rear springs are free, thus accounting for well defined flexibility in the performance of the springs. In order, however, to assure just the performance which is characteristic of Renault cars on the road, shock absorbers, of a most effective design, and of superior materials, are provided in the manner as shown in Fig. 3, and a glance at the details of design will disclose the perfect universal action of the devices used.

From the springs through the axles to the road wheels, the power of the motor is rendered potent, and by way of axles to sustain in service, the front is of the I section, of great strength, and with integral spring perches. The live rear axle is of tubular form, in which the housing over the bevel drive and the compensating gear is of great strength, in view of its shape, which does not prevent it from being light, and it is in this way capable of doing work without introducing complication, if the speed of the car is high.

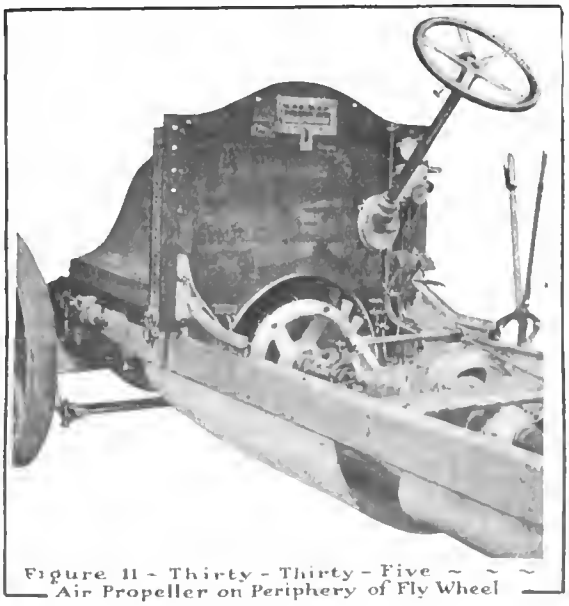

Figure 11 - Thirty - Thirty - Five — Air Propeller on Periphery of Fly Wheel

Wheels, Wheelbase and Control Systems.—The rear road wheels are in driving relation with the differential shafts, which in turn take their power from the compensating gears, and the road wheels are so attached that none of the bending moments are transmitted through the shafts; the tube, which serves for the shaft housing, is designed to take all such strains. The wheels are of

the most approved design in all respects, and the tires adopted on the several models take into account the load and speed to an adequate degree.

Motion is controlled by means of two very powerful brakes, acting on the back wheel hubs and on the differential. These brakes are entirely metallic, and hold equally well backward and forward. The brake acting on the wheel hubs consists of two drums made in one for the wheels, and in the interior of which are cast-iron segments which expand internally against the drums. The expansion of these brake liners against the drums is obtained by rotation of a finger-shaped cam.

These wheel brakes are controlled by a hand-lever placed at the side of the change speed lever at the right hand of the driver. This lever moves on a notched sector, allowing one to leave the brake on or off, whichever position may be desired.

The brake level is joined up to that of the cam, which expands the segments by a steel rod. The adjustment of the brakes is very easy. The brake working through the differential is worked by a pedal. This brake is operated in the same manner as those on the back wheels—expanding cast-steel segments—and is very gradual in its action and easily operated.

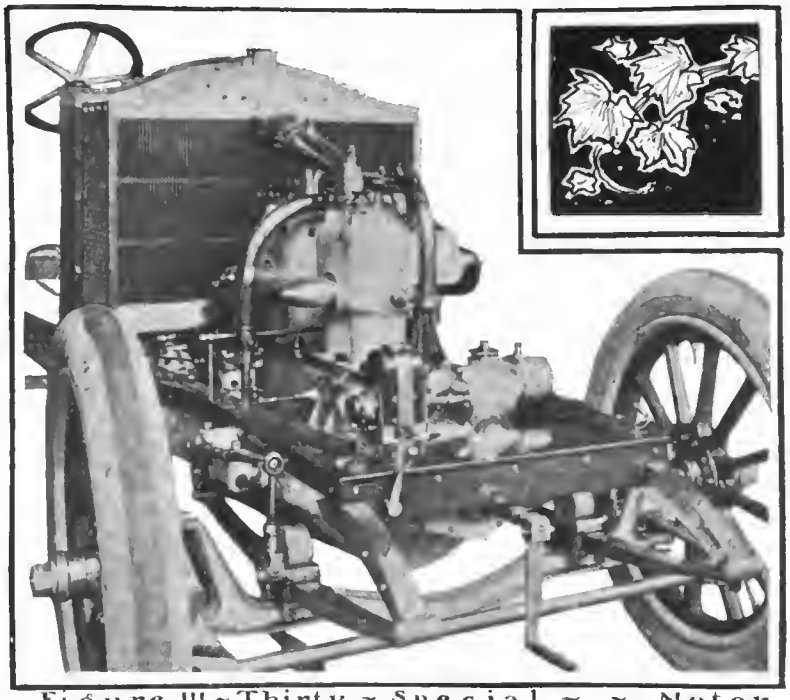

Figure III.—Thirty.—Special.—Motor, Magneto, and Thermo-Syphon Cooling.

Renault chasses are fitted with three push pedals; that on the left hand works the clutch, the middle one the brake, or clutch and brake if desired; the third, on the right, is the accelerator pedal.

The steering is irreversible, and is of the helicoidal type, which is effected by an endless screw. It is very easy, and does not in the least tire the driver, the road shocks not being transferred to him. The movement of the steering wheel is transversal to the wheels by means of a revolving arm fitted on a sector and helicoidal grooved shaft, secured by a ball socket jointed rod to the levers working the wheels.

The wheels are mounted on the journals, which are thus jointed in their sockets to the front axle. In addition, on to the journals are fitted levers, holding between them a connecting rod, by means of which the two wheels are kept parallel one with the other. When the levers are fitted to the journals, there are large tapered squares. This arrangement gives the greatest possible rigidity by entirely avoiding all the shock or rattling of joints and escaping all fear of breakage.

Self-starting Device Makes for Utility.—In special cases the Renault cars, notably the 20, 30, 35, and 50-horsepower models, are fitted with self-starters, of a type in which compressed air is distributed to the cylinders at the propitious time. The same compressed air can be used for the purpose of inflating the tires. This self-starter idea is very reliable, and it is of particular advantage in the cases in which the owner prefers to run his own car betimes. Then it is the more sure way of starting, which is something to take into account these days when gasoline is not up to the high standard of former times, thus making "cold" starting something to ponder over.

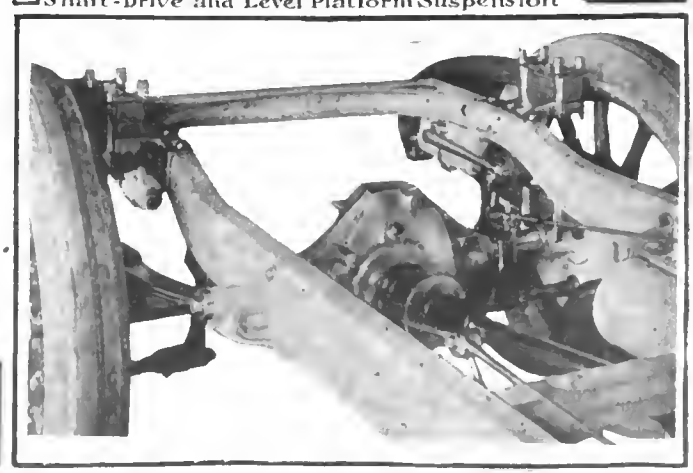
A Sweet Running Motor Furnishes Power.—Renault silence has ever been a mystery, due to the complete silence of the machinery, rather than to the musical notes, as distinguished from discords, which are usually regarded as obtaining in what is called noiseless performance. The motor in Renault cars is small for the power, belonging to the class in which cylinders are cast in pairs, with the mechanically operated exhaust and inlet valves on the same side, L fashion.

The single camshaft is with the cams cut from the solid, and the material is that which will take great hardness without brittleness, which is but a way for saying that the material used is highly kinetic. Likewise, the crankshaft is of a suitable grade of material, taking into account the arduousness of the service, and the desirability of continuity, due to the cost and inconvenience which must follow if crankshafts fail in service.

Ignition is by means of Simms-Bosch high-tension magneto, in which the secondary circuit connects up to Renault spark plugs, which are noted for long life and the entire absence of "sooting" tendencies. The magneto is shown in Fig. 3 and is driven by a helicoidal pinion, from the camshaft, with all parts enclosed.

Cooling is effected by means of the thermo-syphon system, in which the method reaches a high state of efficiency due to the nice manner in which the principle is carried out. The radiator is shown in Fig. 3, just over the flywheel of the motor, and as will be observed the air-propeller is of the type in which the "vanes" are on the periphery of the flywheel, just where they will do the most good. With a superabundance of air to wipe the heat off of the cooler surfaces, coupled with a static head of water, due to the elevated position of the radiator, the success which has attended the Renault system of cooling is easily understood, especially if account is taken of the commodious piping system used and the manner of its application.

Figure IV.—Thirty.—Special.—Shaft-Drive and Level Platform Suspension.



The water piping is straight, of large area, and made of copper, which is noted for its strength and utility in this service. Flexibility is assured by the way in which the design is consummated, and leaks, as the result of service, or due to vibration, are avoided. The neat appearance of the piping adds to the pleasing effect of the machinery, and should repairs have to be made for any reason the piping can be dismantled readily.

The more efficient a power plant becomes the greater is the need of adequate lubrication. While definite and profuse lubrication is a factor for efficiency, yet even so, the very increase in power which naturally follows, demands the greatest certainty of lubrication. In the Renault, for the cylinders, oil is regulated and fed by means of an eccentric on a rod, within the lubricator on the dash of the chassis. The lubricator is of the sight feed type, and besides caring for the cylinders in the manner as above described, crankcase lubrication is assured and regulated by means of a special arrangement of transverse partition in the lower half of the crankcase. The connecting rods are oiled by splash, but provision is made to assure uniformity.

Renault Commercial Cars.—While it is true that the Renault cars are in great prominence in pleasure pursuits, it is not to be said that they are to the exclusion of the same make of cars in commercial work. The company is heavily engaged in the commercial zone of activity, and there are four distinct models of Renault cars available for this class of work. These models cover about everything required from a light delivery wagon to trucks for the heaviest service in important work.

The smallest car is designed to carry 1,200 pounds burden, and the motor is rated at 9-12 horsepower. This is the light delivery wagon, in which the motor is of the two-cylinder type, and the chassis is intentionally designed to place in the hands of men of almost no skill at all. The 10-14 horsepower car is the next size, and this car is rated to carry a load of 1,800 pounds. This is also a car in which the motor is of the two-cylinder type. For heavy work the 14-20 is available, in which the motor is of the four-cylinder type, and the normal capacity of the car is 3,400 pounds burden. This chassis is probably one of the finest propositions possible to devise for the purpose, in which all the parts are especially devised in view of the arduousness of the service, taking into account the lack of efficient care which must be the lot of trucks in the hands of men who are not mechanics and whose early training may be such that they never will be able to wield a monkey-wrench with safety to any piece of mechanism below the ruggedness which will put up with abuse to a vast extent and in divers uncalled for ways.

In addition to the chassis which will do for delivery and truck work, the company has in hand a 20-24-horsepower, four-cylinder "autobus" which is rated to sustain under a load of four tons. This is the chassis used by the New York *Herald* in its most exacting work and it is claimed that the *Herald* depends upon the car to a vast extent. Of course, the commercial cars of the Renault are much like the pleasure vehicles in the main; that is to say, there is the same fine material, the details of design, and the Renault ear-marks with the brand of success burned in them by the fire of skill and experience.

ENTRIES FOR MONACO BOAT RACES BREAK ALL RECORDS

PARIS, March 10.—A total of 97 boats, consisting of 66 cruisers and 21 racers are now entered for the Monaco carnival, March 31 to April 11. The number is a record and exceeds that of last year by 12. For the first time the limited bore regulations, as applied to racing automobiles, will be in vogue for the motor boats, the weight of the hull being limited according to the bore of the engine, and the maximum bore being fixed at 155 millimeters for a four-cylinder engine, as in last year's road races. Many of the boat engines indeed will be those which were used on racing cars last year.

The center of interest lies in the International Cup, which will be disputed by boats of unlimited power for a distance of about 60 miles. As under the Gordon Bennett rules, only three boats per nation can be entered, the nations regularly engaged being America, with Dixie and Standard; France, with Panhard, Levassor and Alla-Va, driven by Brasier engines, unless either of these unlimited boats is beaten in the eliminations by some of the fast 155-millimeter bore craft; England, with Wolseley, Siddeley and a privately owned boat which has not yet been named; Germany, with the Prinz Heinrich, engined by Benz, and the Lizelotte, with Mercedes Grand Prix engine; Italy will have one boat only, the Nibbio, carrying a Fiat 155-millimeter engine.

Other interesting speed tests will be the championship of the sea, a 220 kilometers scratch event for all boats having qualified in their class races, and the mile and kilometer races. In addition to the two American racers, Dixie and Standard, the Western continent will have a third champion in a hydroplane boat built by W. H. Fauber and carrying a Motobloc engine of 155 millimeters bore. This craft, part hydroplane, part boat, will run in the 155-millimeter racing craft, the Championship of the Sea, the mile and kilometer trials, and in the International Cup as a French boat (engines only being considered) if she qualifies in the elimination.

PARIS TO HAVE A NOVEL CHAUFFEURS' COMPETITION

PARIS, March 10.—Every trained autoist knows the sound of his own car sufficiently to distinguish it from a crowd of others, although invisible to the eye. But how many professional chauffeurs can correctly name fifteen different cars merely from the sound of their open exhaust? A Parisian journal believes that there are sufficient experts in the music of the exhaust to warrant the holding of a competition. About fifteen different cars, varying from the modest one-lunger to the powerful six and four-cylinder monster, will be gathered in a large garage some Sunday morning toward the end of the present month. The competitors will be in an adjoining room, where they can hear distinctly, but see nothing. As a preliminary test each of the engines will be started up and run for a few minutes with open exhaust, the competitors listening attentively and taking notes if they desire. The real test will then commence. Each engine will be run for two or three minutes with open exhausts, the competitors to write down on a slip of paper the name of the engine they believe to be at work. The competitor having the largest number of correct replies will be the winner.

The event will doubtless be keenly contested, but will of necessity be confined entirely to professional chauffeurs and repair men. The average automobilist, who may be an expert at distinguishing the make of a car from its noise on the road, has little opportunity of becoming familiar with the roar of its engine alone. Even the exhaust cut out would be more familiar, for the length of piping before the cut out is reached has a considerable influence on the sound, and this is more frequently heard than the directly open exhaust. A sound test of cars under ordinary road conditions would have been equally interesting and would have appealed to the average automobilist.

NATURAL ADVANTAGES OF GAS IN AUTOMOBILES

HOMOGENEITY is a property which is difficult of attainment in mixtures of gasoline and air out of a carhureter of the conventional float-feed type unless the gasoline is volatile in the extreme, and this is not likely to be true if the gasoline is a mechanical mixture of a number of the fractional distillates due to the range of temperature, in the distilling process, which is said to obtain at the present time. It is claimed that the present practice in the production of gasoline is to use all the fractions between 50 and 150 deg. C.

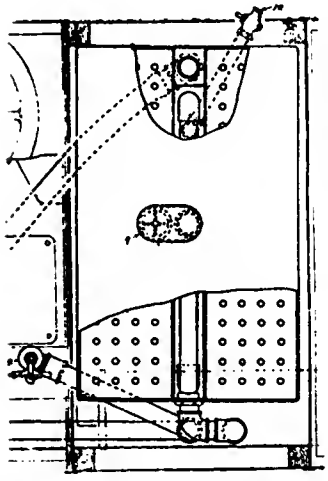


Fig. 1.—Generator with top cut away to show holes in pulp filling.

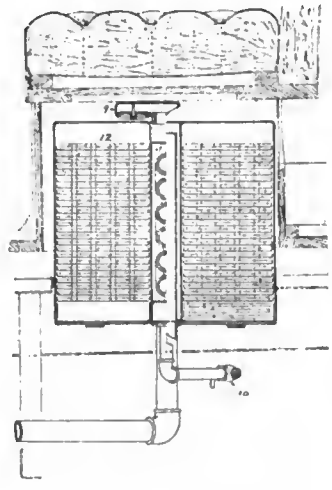

Fig. 2.—Section showing nest of boards with spaces between.

Hexane, the formula of which is C_6H_{14}, is admitted to be the superior fraction of all the distillates from the crude oil used in the production of gasoline, and while the distillers would like to have credit for using nothing but the best for the purpose, the fact remains that gasoline of the present time can scarcely be classed as hexane, nor does it seem to hold any more hexane than the amount required to assist in cranking a cold motor, it being the case that a motor could not be started "cold" in the absence of some of the more volatile of the hydrocarbons.

Carbon in Cylinders Due to Gasoline Used.—Lubricating oil is charged with the crime of depositing carbon on the surfaces of the combustion chamber, and this carbon in turn causes "bucking" and preignition. It probably is true that inferior cylinder lubricating oil will deposit carbon, to some extent, but the main trouble is from the gasoline which will not vaporize until it is allowed to contact with the hot cylinder walls, and this process of reducing the gasoline to vapor is bound to lead to a carbon deposit for the same reason that wood is "coked" if it is heated to a temperature of about 650 deg. C., provided the amount of air present is less than that which would cause complete combustion.

To a very considerable extent the trouble is aborted by preheating the mixture on its way to the combustion chamber or if the air is heated sufficiently before it enters the carbureter. The time was when this process worked very well, indeed, but it is becoming more difficult every day to so heat the air, or the mixture, that globules of gasoline will not enter the cylinders and coke up. The amount of heat required for the purpose is vastly more than is generally well understood, and unless enough heat is supplied, the results will be with a crop of carbon in the combustion chamber.

Any process that will manufacture a homogeneous gas to the entire exclusion of liquid gasoline will serve the purpose, and preheating the mixture is a step in the right direction. The time was when autoists hoped that illuminating gas could be put under compression and that enough of it could be carried in a tank of reasonable size to accomplish the work. It is generally understood that illuminating gas will serve well for the purpose, but it is not possible to store enough of the gas to enable a car to travel far without having to replenish the tank.

Recent Improvements Make Way for the Gas Tank.—That the gas-tank idea clings to the automobile with a tenacity which augurs for inherent utility will be seen in the illustrations here offered. Fig. 3 shows a gas tank and the manner in which it is connected up to a six-cylinder car in which it will be noticed that the carbureter is entirely dispensed with. The entire absence of a carbureter is the best indication of the change over from liquid gasoline to gas, and it is the manufacture of this gas, as it is needed for the motor, that will be given attention at this time.

The gas producer consists essentially of a copper tank, or container, about the size of the conventional gasoline tank, located in any convenient place, as under the seat of the driver, which tank is filled with lamanæ of wood-pulp sheets, superimposed. Each sheet is about 1-4 inch thick, of rectangular shape, and drilled full of holes, each about 1-4 inch in diameter, and spaced about 1 1-2 inches apart. The sheets of wood pulp are separated from each other about the thickness of one of the lamanæ, and the nests of sheets are in two sections.

Between the two sections of the nests of wood-pulp sheets the space is taken up by a heater for the air as it enters on its way to the gasoline-saturated wood-pulp sheets. The heater is made up of a coil of piping in a manner not unlike the radiators used in steam-heating work. The exhaust gases from the motor serves to convey the heat to the radiator. The air enters at the top, passes through the heater coil to the under side of the nests of wood-pulp boards. The admission of air through a check valve, and the suction of the motor, furnishes the required difference in air pressure, so that the air is sucked in.

Since the air cannot turn back through the check valve, it must pass up through the nest of pulp boards, and the holes in the boards furnish the openings, as well as a large surface. Fig.

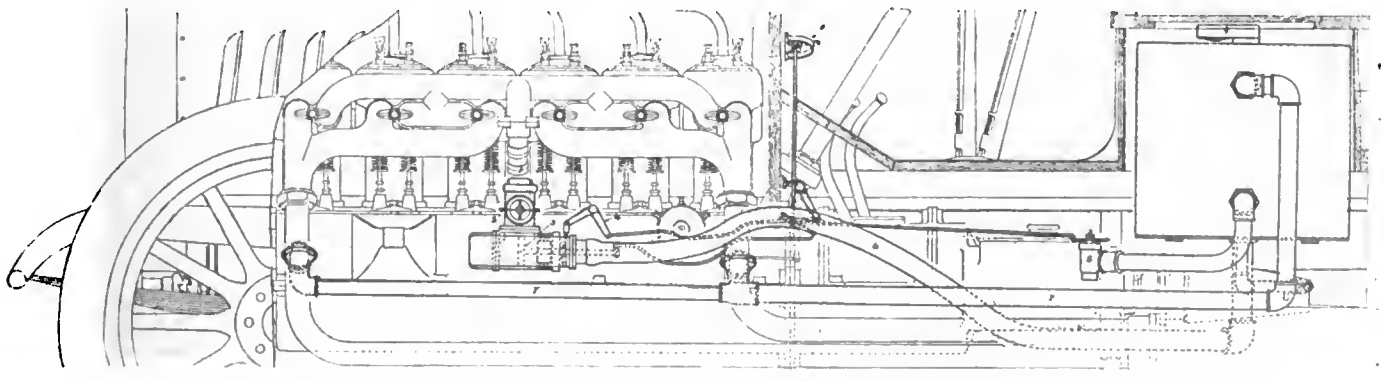

Fig. 3.—Diagrammatic scheme showing the manner in which the generator is used and piping connecting to motor.

t shows the top of the container cut away, exposing the top layer of pulp boards to view, and the small holes will be noticed. The same figure shows the heater in the middle of the container, and Fig. 2 is offered to more clearly bring out the construction features of the system.

The cross-section of the container, as shown in Fig. 2, indicates that there is but very little free space in the same, and in the process, gasoline is spilled into the top of the tank in sufficient quantity to saturate the wood-pulp mass. The amount of gasoline required is about 60 per cent. of the amount which the tank would hold if the wood-pulp system were not present. Excess gasoline is not required, and in the process the heated air as it passes up through the holes in the pulp boards wipes the vapor of gasoline off of the surfaces, and in view of the heated condition of the air, it is in fettle to become enriched, even if the gasoline is of a poor quality.

Through the good office of a valve devised for the purpose the rich mixture is diluted after it leaves the tank, and the device is so ingenious that the motor is enabled to draw just the quality of mixture of a homogeneous gas as will best serve the purpose, while the motorist is enabled to alter the proportions at will, taking into account the road conditions, atmospheric influences, and the properties of the gasoline, as the supply reduces in the tank, leaving the heavier residuum.

There can be no explosion of the gas in the tank for the reason that the same is not sufficiently diluted with air to render it explosive. If all the gasoline is used up, in so far as it can be, what is left can be ignited without danger of any sort for the reason that the same will not be highly explosive, and the amount that can hide in the free space is not sufficient to do any damage at all. As will be seen, then, there is no danger to be attributed to the presence of gasoline in a car, provided it is concealed in wood pulp in the manner in which these generators are built.

From the economy point of view it seems almost unnecessary to more than point out that what is wanted in any case is a homogeneous mixture, such as is made in this system, and since the system precludes the chance of dribbling liquid gasoline along the roadway, taking into account the homogeniety of the same, the radius of travel of a car is about the same as if the tank were filled with gasoline of the conventional sort without the packing of wood pulp. In the meantime the motor will deliver more power with the better mixture, and carbon formations in the cylinders are aborted. The International Generator Company, at 244-250 West Forty-ninth street, New York City, is very active in the manufacture of this system, and the demand is quite in keeping with the advantages following its use.

CHAIN OF ELECTRIC STATIONS PLANNED.

To further the development of the use of electric automobiles, a large gathering of those interested was held recently at the Boston Athletic Association, the manufacturers, the agents, the electric lighting companies and the battery makers being represented, and as a result steps are being taken to thoroughly canvass the whole electric vehicle situation. Numerous garages and charging stations will be located at advantageous points along popular touring routes, according to a well-laid plan, so that owners of these types of machines may tour without fear of running out of power, even though the battery capacity of the machines may vary from 40 to 70 miles or more.

A scheme of battery relay stations was discussed and found to be feasible if concerted action is taken, and regular garage men will be instructed in the use of charging outfits. Among those active in the new work are the Waverly Electric Company, of Indianapolis, and the Electric Storage Battery Company, of Philadelphia, and other concerns are realizing the importance of their policies. The new movement, if it can be made successful, will be one of great importance, for there is a recognized field for electric machines, and a campaign looking to the more general adoption of them is a commendable one.

NEW DETACHABLE LINK CHAIN IS NOVEL.

Fame and Diamond chains entered into a lasting partnership and linked the automobile to success, despite the hamperings of road inequalities, lack of designing experience and the fearful strains that come. In the earlier days when it was extremely difficult to get materials so good that dependance could be put in them under the conditions demanded in detachable work, it was fitting to bow to the dictates of prudence.

Time wrought changes in materials and in methods of manufacture, as well as in the treatment of the finer grades of steel, with the result that Diamond chains have long been made of steel, the nature of which augurs for success under the most severe conditions of service, and the day of the "detachable" made bold to proclaim itself.

It is not because chains are in any way prone to fail in service that the detachable idea commends itself, nor can it be said that the chain question has been much of a factor in the trouble end of the average automobile, whereas, in the better class of cars, it is the chain that stood for sturdy reliability in defining the word. But, the time must come when the best device that man can build will reach the fag end of its life, and the great question then becomes one of prolonging the hoary old age of the faithful servant.

Diamond Detachable Chain Showing Locking Mechanism.

The Diamond Chain & Mfg. Co., of Indianapolis, Ind., recognizing the potency of the idea, recently brought out a chain for use in automobile work, into which is incorporated the detachable principle. The cut shows a link in the chain in which a thin strip steel lock on top of each outside link slips into a groove around the rivet surface and turning on one rivet as a center slips down into a similar groove on the other rivet, thus preventing the side bar proper from coming off. The strip is itself locked into position by being slightly warped inward, and having at its center an inward projection which snaps into a depression in the side bar. Once snapped into place, the strip can't change its position unless an intentional upward pressure is exerted on the clip at the end. The hole in the side bar is so reamed that when the bar is pressed into position, there is perfect bearing contact between the rivet shoulder and the side bar throughout the thickness of the bar.

High Grade Materials Lend Stability.—Billets of special analysis steel are used in the process, all under the eye and control of the makers of the chains. Nickel steel is used for such parts as demand the properties of metal of this sort, and case-hardened rivets in conjunction with seamless rollers help in the production of accuracy, in which all the conditions as follows are adequately taken into account: (a) limit of fatigue, (b) elastic limit, (c) ultimate strength, (d) elongation, (e) variation and (f) backlash. The process, from start to finish, is conducted by the company in the absence of all outside influences.

In the working up of the material with the idea of affording the greatest possible length of satisfactory service, the bearing surfaces are vastly more than the average autoist would have any idea of, and every means is taken to assure permanent fit and alignment of the links in the chain. Noise, that vague specter of the autoist, is kept out of the system if the chain is accurate and if the sprockets are rightly cut, provided the chain holds to the dimensions agreeable to the original plan. It is in this respect that the makers of the "Diamond" claim to have culled perfection and dressed it in its simplest form.

GOOD AND BAD LAWS PROPOSED IN WISCONSIN

MILWAUKEE, Wis., March 15.—At least eleven statutes relating to the use of automobiles have been introduced into the legislature of this State, but it has been so busy with other matters that it has not had time to consider them, and perhaps the only legislation that will be effected will be that for good roads. Of the bills proposed governing the automobiles there are several that are worthy of the support of the autoists of this State, while others will have to be fought. Two are identical and would change the present law to make the initial license fee $2.00, and $1.00 for each annual renewal. This meets with general approval, as does one to prevent anyone under 17 years of age from operating a machine, and one which cuts out speed limits, making it a penal offense to drive recklessly or when under the influence of liquor. Still another bill would prohibit the placing of bumps or other obstructions in highways, and a sixth makes it a misdemeanor for anyone to use an auto without the consent of its owner.

Of narrow-minded and thoroughly pernicious origin are four bills, and a determined stand will be made against them, if the members of the State Automobile Association will work together. One provides for an annual registration fee of $5.00 for machines not exceeding five horsepower, $10.00 for cars not exceeding 10 horsepower, and fifty cents per horsepower for each additional horsepower above 10. If a car should be sold a reregistration would be required and all would expire on January 1. The dealers would have to pay $40.00 annually, with $5.00 for each extra set of number plates. Another of the bills is patterned along the same lines but bases its classification upon weight. Equally nonsensical with these is a proposal that hereafter the maintenance of guide boards by the several towns shall be optional instead of compulsory, and it can readily be seen how many towns would bestir themselves upon such a matter. The remaining obnoxious bill would allow each city to locally control the speed and use of automobiles within its own confines.

One bill has been introduced, upon which the Association has taken no stand, providing for a State inspection of all gasoline and prohibiting the sale of gasoline testing below 65 degrees. The oil people claim this will tend to raise the price of gasoline.

OHIO LAW IS AMENDED AT LAST.

COLUMBUS, O., March 15.—By the amendments to the State automobile law enacted at the recent session of the Ohio General Assembly, every license expires on December 31. Heretofore licenses expired one year from issuance, which caused the State automobile department considerable confusion. Each year the color of the tags to be placed in front and in the rear of every machine will be changed, making it possible for the police departments to ascertain whether the license for the current year has been paid. The words Ohio and the year will also appear on the tag. Motor trucks and drays which were formerly exempt from the operation of the law, are now included, making it possible for the State department to regulate such classes of vehicles.

Section 31, providing for records in each of the 88 counties, as well as in the State automobile department, of every conviction for violation of the law, was repealed entirely. The old law provided that every conviction of fast or careless driving should be recorded with the clerk of the courts in every county. Since no other misdemeanor or crime is so registered, it was thought to be a grave injustice and class legislation that would not stand the test of its constitutionality.

LEGAL FIGHT NOW ON IN CHICAGO.

CHICAGO, March 15.—Enough of the necessary money having been raised, the fight against the Chicago wheel tax has been begun and will be carried right up through the Supreme Court and a precedent established, not only for this city, but for the whole country. The kick is directed against the use of the tax money and the seating capacity as a basis for the tax ordinance rather than the weight of the car.

The objections to the ordinance and its results were so widespread that the Automobile Trade Association decided to fight it if outsiders would help to raise the money to pay for the legislation. The sum of $10,000 was settled upon by the committee.

To quote the treasurer, Henry Paulman, "We feel that there should be some sort of a tax, but we use the boulevards extensively, which are under State control, and therefore get none of the money paid in to the city. We want the money expended where it will do the most good to the men who are obliged to pay it. Probably the best way to collect a tax from the automobilists would be to have the charge included with the State license, with a part of the money set aside for the city." This should be an easy thing to do, and with slight expense.

INDIANA MODIFIES ITS ROAD LAW.

INDIANAPOLIS, IND., March 15.—A radical change in the road laws of Indiana, that will probably mean a decrease in the building of new roads, has been effected in the repeal of the three-mile road law by the legislature. In a new law the procedure is changed, and the referendum system adopted. The new law provides that fifty resident property owners may petition to the county commissioners for an election to decide whether or not a road shall be built. If a petition is not presented protesting against the election and signed by 55 or more property owners, the commissioners are required to order the election.

Under the old law, upon the petition of fifty property owners, the commissioners were required to order the building and improving of a road, without the formality of an election. The only proviso was that the proposed road should not be more than three miles long and that it must connect at each end with improved roads or be traveled by a United States rural mail route. While the three-mile road law was in effect, roads to the extent of $8,000,000 a year were built and improved under it. Farmers raised the principal objection to the old law, because residents of small towns petitioned for brick streets under the law and the whole township had to bear the expense.

MARYLANDERS WILL OPPOSE THE SWANN BILL.

BALTIMORE, March 15.—Secretary Frank W. Barling, of the Automobile Club of Maryland, has organized the autoists of Union Bridge, this State, for the purpose of co-operating with the club in its fight against the passage of the Swann automobile law, now before the Maryland Legislature, particularly that section of the same which provides for what is considered a new special rate. Raymond K. Angel has been selected as chairman *pro tem* of the new local association.

DELAWARE AUTOISTS PROTEST AGAINST TAX.

WILMINGTON, DEL., March 15.—Official protest against the bill now pending in the Delaware Legislature, proposing to tax automobiles as personal property, was made last week when John J. Satterthwaite, president of the Delaware Automobile Association, and other prominent members appeared before the State Senate and stated their reasons for opposing the bill, and pointing out its apparent injustice. No action has been taken upon the measure. That the association will put up a good fight against the measure is assured.

THE FUEL QUESTION IS SERIOUS.

The reason why gasoline was used to the practical exclusion of kerosene oil in automobile motors was because the lighter fractions of the distilling process possessed the more volatile properties, and could be more completely burned in the cylinders, thus rendering up more power per pound of fuel used, and in the process carbon was not left as a residuum.

When gasoline was to be had for the purpose, it was predicted that the price would soar, for it was well understood that less than ten per cent. of crude oil would distill off in this form. It was then that inventors were active, and a means for burning kerosene oil was sought as if much depended upon success.

In due course the distiller of crude oil made bold to try a hand at inventing, and the gasoline furnished to automobile users is really a compound of all the fractions down to the kerosene distillate, with just enough of the lighter fraction to assure that a motor can be started cold. The result is that the fuel enters the cylinders as liquid—to a vast extent, at any rate—and in the combustion process the fuel is broken down and the carbon is "coked" out.

The whole thing was accomplished by such easy stages that autoists failed to account for the presence of excess carbon in the cylinders, unless to lay it to the lubricating oil, and the question of ignition gradually improved so much that the firing of the charge was not attended by serious difficulty. In the meantime advanced experimenters located the real trouble, resulting in fuel systems in which the exhaust heat is utilized to vaporize the fuel so that it cannot enter the cylinders in liquid form, there to "coke" up.

While it is true that the fuel is not what it was supposed to be, it is equally true that the change resounds to the greater advantage of autoists in general, if it can be said that the heavier fuel can be made to burn without leaving a residuum, provided the power of the motor will be quite as good, and if flexibility will be no less. Starting "cold" is something to take into account, but this is a matter which seems to be in good fettle.

TRACTORS PLEASE RURAL POPULATION.

Anybody who is not familiar with or who does follow the progress of agricultural machinery will be very much surprised with the recent advances in this field, particularly among the tractors. These clumsy-looking machines bid fair to put the farm horse out of business, not because of its speed, but because of its inherent inability for sustained labor. Thus upon plowing the length of one side of a 200-acre farm, the horse must rest before attempting the return trip. This rest, when multiplied by the number of furrows ploughed in a day, means a large loss of time, possibly at a season when every minute is valuable. On the immense farms of the West and Northwest, some of which are of ten thousand acres and more, it is readily seen that this loss, whatever it may be, is again multiplied, this time by fifty or more. From the above, it is apparent that a self-propelled tractor, which can drag a gang plow and thus turn up six or more furrows at a time, do a series of these in less minutes than the horse takes for one and keep it up all day without a minute's rest, has advantages that the farmer must see and appreciate.

The timely trials of last year which took place at the Winnipeg Fair showed, as had never been shown before, what the tractor could do when given a fair chance and intelligently handled. A brief mention of some of the best performances will be appropriate. Thus, the winning machine ploughed 3 1-4 acres of virgin prairie sod, which a heavy rain had converted into sticky Manitoba "gumbo," in two hours on a consumption of 8 1-8 gallons of gasoline. This is an average of but 2 1-2 gallons per acre, which at 14 cents per gallon makes the cost for fuel just 35 cents per acre. This machine was of 30 horsepower, having four 6 1-4-inch by 7-inch cylinders, was operated by one man and pulled six 14-inch bottom gang plows.

Similar and equally valuable results were obtained in the French trials, which were not as extensive, however. These results show the farmer, who works on a small margin of profit at best, what may be done with the "new fangled" machinery, and thus points out an additional source of economy.

The winning machine and many of the others were so equipped that after the first furrow has been plowed, the machine steers itself automatically. This allows the man in charge to walk beside the plows and observe the work as it is done. The necessity for more than one man does not exist, therefore, an additional source of economy is opened up, this being a more real blessing to the farmer than the actual saving in cost, as farm laborers are particularly hard to get and keep.

SPEARE SUCCEEDS HOTCHKISS AS HEAD OF A. A. A.

BOSTON, March 15.—Lewis R. Speare, of this city, has been elected to the presidency of the American Automobile Association, to succeed William H. Hotchkiss, who has resigned, to give his full attention to his new duties as Insurance Commissioner of New York. During the automobile show the regular quarterly meeting of the board of directors of the A. A. A. was held, and Mr. Speare, the president of the Bay State Automobile Association, chosen to head the national body, filling out Mr. Hotchkiss' term, which expires on December 1.

At this meeting also a strong addition was made to the A. A. A. through the election to membership of two more State associations, the Colorado State Automobile Association, with six clubs, 650 members, and the South Dakota Motor and Vehicle Association, with six county organizations, 350 members, bringing the total number of State bodies to 27. The Lookout Mountain Automobile Club, of Chattanooga, Tenn., was elected as an unfederated club. George C. Diehl, of Buffalo, a member of the board of governors of the Automobile Club of Buffalo, county engineer of Erie County, and an active participant in all good-road movements, was appointed chairman of the national good roads board, to succeed C. Gordon Neff, of Cincinnati, whose resignation was accepted with regret. P. M. Milner, president of the Motor League of Louisiana, was elected a director.

The deed of gift of the Cobe trophy, donated by Ira M. Cobe, president of the Chicago Automobile Club, for a stock chassis race, was accepted and referred to the Contest Board, with power to conduct the event. Those present at the meeting were: Lewis R. Speare, president of the Bay State A. A.; A. E. Bliss, president, and A. D. Converse, vice-president of the Massachusetts State A. A.; J. P. Coughlin, president of the Worcester A. C.; A. E. Lerche, president of the A. C. of Springfield; W. W. Brown, president of the A. C. of Vermont; S. A. Miles, general manager of the N. A. A. M.; E. P. Chalfant, general manager of the A. L. A. M.; F. B. Hower, chairman of the A. A. A. Contest Board; C. H. Gillette, secretary of the Connecticut A. A.; F. H. Elliott, secretary of the A. A. A.; W. B. Lasher, A. C. of Bridgeport, Conn.; L. J. Powers, Jr., Springfield; W. H. Chase, Wachusett A. C.; Francis Hurtubis, Boston; E. F. Whitmore, Willimantic, Conn.; H. R. Burbeck, North Adams, Mass.

Chairman Powell Evans, of the Touring Information Board, has secured the official recognition of the United States Government as the national organization of motorists. This has been brought about by the A. A. A.'s having become a conferee of the National Conservation Commission, Mr. Evans being the Association's conservation committee chairman, and not alone through its interest in good roads can the A. A. A. work prove beneficial in this connection, but also in other ways. This is suggested in a letter to the commission from Chairman Evans, in which he suggests that through the influence of the A. A. A. every autoist in the country can, within a few weeks, be mobilized into a most efficient scouting force, to give notification promptly of any outburst of forest fires, as well as possibly giving aid in their suppression. Mr. Evans therefore urges each club to pass a resolution pledging its members to notify by telegraph the proper officer of any State of any fire observed.

Quarterly Meeting of the A. A. A. Board of Directors, Assembled in Boston, March 15, President Speare Presiding.

AMERICAN MOTOR LEAGUE GIVES UP GHOST.

Apparently the American Motor League has passed away, though its demise has been a lingering one, owing to the individual activities of Isaac B. Potter, its president, who was the head of the L. A. W. in its palmiest days when it had a membership of 107,000. The former offices of the League in the Vanderbilt Building on Nassau street, New York City, are untenanted, and, according to the New York *Globe*, Mr. Potter has become a resident of Denver, where he intends to continue practicing law. At one time an amalgamation seemed assured of the A. A. A. and the A. M. L., but the joint committee of the two bodies failed to agree upon a satisfactory constitution.

JERSEY AUTOISTS IN EVIDENCE AT TRENTON.

TRENTON, N. J., March 17.—Although a large number of automobile owners to-day appeared in the Assembly to urge the passage of the Colgate bill, they were disappointed, for the bill went over until to-morrow, having already passed its second reading in the House. At the same time they protested vigorously against the plan of the legislature to divert $120,000 from the motor vehicle department into the State treasury.

CHICAGO MAKES PREPARATIONS FOR COBE TROPHY RACE

CHICAGO, March 15.—By the appointment of a board of executives and other officials, and the inspection of the proposed course, active preparation for the road carnival of the Chicago Automobile Club on May 29 and 31, which will include a light car race upon the first day, and the national contest of stock chassis for the Cobe trophy on the second, has been commenced. A thorough inspection of the roads was made in a trip yesterday and the possibilities of the circuit have been examined by experts. The excellence of existing conditions surprised those who will have the events in charge, so that a race that will compare with the most successful national events is predicted.

The club has decided to give the conduct of the meet to its contest board, Joseph F. Gunther, A. J. Banta and C. G. Sinasbaugh, while the various executives will consist of eleven men, in whose hands will be vested the power to carry on the work. Frank H. Trego has been made general executive, having a general supervision of the details; N. H. Van Sicklen, Sr., will superintend the construction of the course; F. E. Edwards will attend to the construction of the grand stands and the fencing while other departmental chiefs include the following: Technical, David Beecroft; finance, Ira M. Cobe; house, Burley B. Ayers; hospital, Dr. L. W. Bremerman; diplomacy, Harold H. Wheeler; publication, Fred W. Van Sicklen; publicity, C. G. Sinsabaugh. The committee on public safety will have for its chairman the colonel commanding the Indiana militia, which, it is hoped, will be detailed to guard the course. A Chicago delegation will visit Governor Marshall at Indianapolis this week to ask that soldiers be assigned to this work. It is hoped the Governor will consent.

In the trip over the course yesterday it was found that the stretch between Crown Point and Cedar Lake is the most winding, but it is believed that while the curves may slow the drivers some, they will not be dangerous. From Cedar Lake to Lowell, a distance of six miles, there is a perfectly straight road, then comes the turn into Lowell and out on to a broad road, that runs three miles to the southeast corner of the course. This bit of road has a couple of turns, one a short S, but in general is one of the best parts of the course because of the width and smoothness of the roads. Turning from this leg there is a 10-mile straight way to Crown Point, where great speed can be made. On this leg, near Crown Point, it is planned to erect the grand stand, probably within a mile of Crown Point, because of its accessibility.

"I consider the Crown Point-Lowell course superior to the one over which the Braircliff was run, and I believe it is the equal of the Vanderbilt, outside of the Motor Parkway strip," said N. H. Van Sicklen after the inspection trip. "It is going to take a lot of work to put the course in shape, but I believe that a liberal expenditure of money will give us a circuit that will be capable of producing a winning average of 50 miles an hour, which is not bad when it is remembered the race is for stock cars. The roads are generally wide enough for the cars to pass each other. The circuit is about 24½ miles in length, instead of the 22 that had been estimated, so Chicago will have a circuit as good as any in the country."

FLORIDA'S MEET MAY RESULT IN NEW RECORDS

DAYTONA, FLA., March 17.—The annual races on the Ormond-Daytona beach, scheduled to begin next week, Tuesday, and continue the balance of the week, may result in some new straightaway speed records, for the entry list promises to contain some of the most noted cars in the country. Owing to the lateness in the announcement of the meet itself, the entry list is going to be kept open until the eleventh hour. The Florida East Coast Automobile Association is busily engaged in making final preparations, and the resourcefulness of W. J. Morgan, the manager of the meet, is certain to bring forth a generous entry.

One of the noted cars entered is the Benz, which Hemery drove in the Savannah Grand Prize. This has been bought by Hugh McIntosh, the well-known Australian sporting man, who is here to see how it will perform in the hands of D. L. B. Brown, who made the best amateur record a year ago. Ralph De Palma is a Fiat participant, and H. J. Kilpatrick will drive the Hotchkiss, which was the best performer in the Jamaica (L. I.) straightaway trials. Herbert Lytle will also participate, probably with an American, and George Robertson, the Vanderbilt winner is a possibility.

PERMISSION FOR FAIRMOUNT PARK RACE GRANTED

PHILADELPHIA, March 15.—Thoroughly pleased with the result of the Founders' Week 200-mile stock car race, which was held upon its fine roads last fall, the Fairmount Park Commission on Friday granted to the Quaker City Motor Club the right to repeat its successes upon the same course on October 7 of this year. Thus this club is the first in the country to set its date for what will undoubtedly be one of the most important events of its kind held in this country this year. A single dissenting vote was cast by the commission, recognized to be one of the most conservative in the city.

Formal application was made through a letter to the board at its regular monthly meeting, in part saying: "It is the intention to use, if possible, about the same course which was followed in the Founders' Week race, and to conform to the same rules and regulations, although we wish it understood that such conditions as you may see proper to impose will be strictly complied with." The same responsibility for the roads and the same method of policing the course will be enforced.

So well did the members of the commission favor it that the letter was hardly discussed, and the club will now have to deal only with the Committee of the Park on Superintendence and Police, working with it in planning for the big contest, as arranged by the Park Commission. The result of this is not only exceedingly gratifying to the Quaker City Motor Club, but also to all Philadelphians, and it is freely predicted that the crowd of 400,000 people which saw last year's event—a record attendance—will be materially increased.

Although the big road race will be the star card in the Quaker City Motor Club's programme of enlivening affairs, it will not be the only one by any means and the contest committee is outlining a busy season. A roadability run will be held late in April, as a preparatory stunt to a big four-day endurance contest to Pittsburg and return, scheduled for May 19 to 22. It is probable that this date will be slightly changed because the Norristown Automobile Club has already set its run to Hagerstown and back for May 18 and 19.

What the Clubs are Doing These Days

HARTFORD AUTOISTS DECIDE TO EXPAND.

HARTFORD, CONN., March 15.—General expansion and broadening the influence of the Automobile Club of Hartford, in the interests of automobilists, is the matter of greatest import to its members since a well- attended meeting was held at the club rooms in the Allyn House on last Friday evening.

The acquirement of a permanent clubhouse has always been a topic of discussion, and there seems to be a more strenuous demand for one now than ever before. The membership is now about 350 with bright prospects for an increase before spring. A committee, consisting of General Wallace T. Fenn, chairman, Edgar L. Ropkins, F. W. Stickle, N. F. Allen, C. H. Veeder, C. D. Rice, H. P. Maxim, Geo. W. Merrow, A. G. Hinckley, F. A. Morley and F. W. Dart, was appointed to draw up suggestions for the expansion of the club. They will report at a banquet to be held on Friday evening, March 26.

The club by unanimous vote has gone on record as being heartily in accord with the proposition to erect a bridge at the mouth of the Connecticut River connecting Lyme and Saybrook. It would obviate the use of the obsolete ferry which plies at the mouth of the river. The Automobile Club of Hartford will be more of a factor in the sport this season than ever before. The forthcoming endurance run, from all reports, will be the best ever held around here. Every member is anxious to have the organization listed among the best of the country. When the roads are in good shape the sign post committee will continue its campaign where the coming of cold weather necessitated a stop. Every road of any importance will be amply posted for the benefit of all who motor. Since the club inaugurated an anti-scorching campaign some time ago there seems to have been a decided let-up on the part of the reckless element.

CONGRESS STEALS MARCH ON AUTOISTS.

WASHINGTON, D. C., March 15.—The Automobile Club of Washington has decided to put up a vigorous fight against the imposition of an annual wheel tax on automobiles. During the closing hours of Congress, a rider was tacked on to the District appropriation bill, providing that hereafter there shall be assessed and collected an annual wheel tax on all automobiles owned and operated in the District of Columbia. Cars having seats for two persons will pay $3, and those having seats for more than two persons will pay an additional tax of $2 a seat.

This provision was included in the bill without the knowledge of the automobilists, and had been a law a week or more before it was known to any one except a few members of Congress. Naturally a big howl went up from the automobilists and the matter was discussed at length at the club meeting on Saturday evening, it being resolved to fight the provision to the last ditch, on the ground that it is class legislation of the rankest sort. A resolution was passed authorizing the club's secretary to notify every member of the organization not to pay the tax until compelled to do so by the Federal courts. It has not as yet been decided whether the Club will institute a test case.

A SMALLEST CITY WITH AN AUTO CLUB.

EVANSVILLE, WIS., March 15.—This little city will soon have an automobile club, which will affiliate with the Wisconsin State A. A., a member of the "Three-A." Twenty-two prominent residents of the little city have purchased cars, and at the suggestion of the Milwaukee Automobile Club, are agitating the formation of a local club. If this is done, Evansville will have the honor of being the smallest city in Wisconsin to have a club.

EARLY POPULARITY OF NORRISTOWN RUN.

NORRISTOWN, PA., March 15.—The contest committee in charge of the endurance run of the Norristown Automobile Club, which will be held over a 400-mile route between this place and Hagerstown, Md., May 18 and 19 next, have thus early received so many requests for entry blanks as to warrant the claim that the run will be one of the largest, as regards the number of contesting cars, ever held in this part of the country. Not less than 75 cars is the committee's claim. The route as finally selected provides for controls at Coatesville, Lancaster, York, Frederick, Md., and Hagerstown, Md., the overnight stop—190 miles—and at Gettysburg, Harrisburg, Lebanon, Reading, Pottstown, and finish at Hotel Montgomery, this city—210 miles.

Two classes of entries are provided for—the trade and the laity. All manufacturers and agents are eligible to the former class, which is sub-divided into touring car and runabout divisions; the latter class is open to any club member or non-trade member of the A. A. A. The details of the run will be looked after by the following officials: Referee, John H. Rex; business- manager, Oliver F. Lenhart; starter, Wayne Davis; assistant starter, A. D. Hallman; chief checker, Earl Wentz; associate member A. A. A., Harry Lasher. At the conclusion of the run the cars will be impounded and critically examined by the following technical committee: Linn De Haas, Henry Lewis and Lawson Ballard. A "pathfinding" expedition will go over the route on March 31, April 1 and 2 to arrange for checking stations, hotels, accommodations and other matters.

SYRACUSE CLUB HOLDS SEVENTH BANQUET.

SYRACUSE, N. Y., March 15.—Few automobile clubs in this country can boast of sufficient age to hold a seventh annual banquet, but the Syracuse Automobile Club is able to do so, and on last Wednesday evening had its seventh celebration, there being about 200 guests present, and the affair was a success from start to finish, all checking in at the windup without a penalization. C. Arthur Benjamin was toastmaster, and in his remarks predicted that the present membership of 230 would be increased to 450 before another year has passed.

President Hurlburt W. Smith made an interesting address, telling of the history of the organization since its inception in 1901, when the first run was held over the State fair boulevard, and one man reached the toll gate.

Mayor Alan C. Fobes, Professor W. K. Wickes, Rev. D. B. Thompson and others also spoke. The committee in charge was composed of H. W. Smith, W. L. Brown, D. E. Brown, C. E. West and Forman Wilkinson.

MARYLAND AUTOISTS AFTER JOY RIDERS.

BALTIMORE, March 15.—The Automobile Club of Maryland, at its regular semi-monthly meeting, decided to furnish the police department with slips, containing the names of chauffeurs and the number of cars, so that the policemen can report any of those seen in questionable localities. By this means the club expects to be successful in ending the persistent joy riding by chauffeurs.

GRAND RAPIDS CLUB PLANS HILL CLIMB.

GRAND RAPIDS, MICH., March 15.—The Grand Rapids Automobile Club has decided to promote a hill climb, with an A. A. A. sanction, to be held some time in the near future. The events will be divided into several classes, under the direction of W. D. Vandecar, chairman of the tours and contest committee.

ROCHESTER HAS ITS SECOND ANNUAL SHOW.

ROCHESTER, N. Y., March 15.—Rochester's second annual automobile show was opened by Mayor Edgerton this afternoon in Convention Hall, under the auspices of the Rochester Automobile Dealers' Association, with eighty cars upon the floor. Every automobile dealer in the city is represented, and around the galleries and balconies are located the accessory and supply exhibits. The whole structure has been brilliantly decorated and illuminated for the occasion. The exhibition has proven to be of great interest to automobilists, not only in this city, but also in a great many surrounding towns. To the dealers and visitors, alike, not only in point of decorations but also in the merits of the machines shown, the event gives promise of being highly satisfactory. The building has been so arranged as to give the tradesmen as much space as possible, and it is expected that still more machines will be added to those now in place as the week goes on.

A number of the cars were shipped directly to this city from Boston, while others have been going the rounds of the shows in the Middle West. Two Rochester factories are represented, the Selden and the Cunningham, the latter a newcomer. Herewith are the car exhibitors:

Hollis-Rand Company—Overland.
D. M. Dorman—Winton.
Gabel & Hill—Babcock electric.
C. E. Hartson—Mora.
C. L. Whiting—Buick.
Arthur McNall—Peerless, Pope-Hartford, Rauch & Lang electrics.
L. B. Kirkpatrick—Oakland.
Genesee Motor Vehicle Company—Maxwell.
Benson & Hughes Motor Vehicle Company—White, Rambler.
Rochester Automobile Company—Packard, Baker, Lansden.
A. M. Zimbrick—Stoddard-Dayton, KisselKar.
Thomas J. Northway—Ford, Reo, Marion.
Union Motor Company—Mitchell, Chase motor wagon.
Selden Sales Agency—Selden.
Mabbett-Bettys Motor Car Company—Cadillac, Stevens-Duryea.
Caledonia Avenue Auto Company—Detroit electrics.
Smith Sash & Door Company—Welch.
James C. Dryer—Cunningham.

The show will continue throughout the week, during the afternoons and evenings a number of social features being scheduled to accompany it, and concerts given by the Fifty-fourth Regiment orchestra and band will tend to heighten the festivities.

MILWAUKEE SHOW REVEALS LARGE SALES.

MILWAUKEE, WIS., March 15.—After the closing of the big show at the Hippodrome, last Saturday night, the dealers and exhibitors, to a man declared it the best ever. The number of cars sold has surprised even the most sanguine of exhibitors, whereas the croakers have vanished into thin air.

The automobile club is rejoicing, too, because the large and well sustained attendance, totaling over 25,000, will result in swelling the club treasury by several hundred dollars. Had it not been for the unfavorable weather on the closing night, a record for attendance would have been made then with a corresponding effect on the receipts.

Saturday, however, was the big sale day and despite the bad weather the demonstrators were kept busy from morning to night, and a big bunch of orders were booked.

The first result of the enthusiasm has manifested itself in the decision to repeat next year. If this is held, it will be next fall at the time when the new models come out.

ALL SYRACUSE DEALERS WILL EXHIBIT.

SYRACUSE, N. Y., March 15.—If all the automobile dealers of this city could be given the amount of space for which they have applied, there would have to be an overflow meeting in connection with the show which will be held here from March 24 to 27. All of the members of the local trade have asked for space, as well as numerous supply men and accessory dealers, and all will be given just as much room as possible. Dai H. Lewis, who will have entire management of the event, is expected to arrive shortly and take charge. Mayor Alan C. Fobes will open the exhibition.

LATER APRIL DATES FOR NEW YORK CARNIVAL.

For a number of important reasons, conflict with Easter and Holy Week, the desire for more settled weather conditions, and the need of more time for preparation, has influenced the carnival committee of the New York Automobile Trade Association to postpone the week of festivities from April 5 to 10, as at first planned, to the week of April 26, closing upon May 1. The local trade seems much pleased with this move and more hearty support than ever has been promised.

At a recent meeting of the committee a number of important matters were considered. One of them is the determination to give as prizes for decorated cars $2,000 in cash, and to allow in line only those makes of machines whose metropolitan representatives have contributed to the carnival fund, although at the same time it has been deemed advisable to prohibit any car from carrying any name or mark, except its number. R. G. Howell will have charge of the parade this year, as he had last.

Headquarters for the carnival committee has been located at the main store of the American Building, at Columbus Circle, through the courtesy of W. R. Hearst, with Secretary Walter C. Lee in charge. In electing the king and queen of the carnival, to preside over and lead the pageant on the Saturday afternoon, it is probable that a popular vote will be taken.

The dates as they now stand are as follows: Monday, April 26, hill climb; Tuesday, April 27, straightaway races and speed trials; Wednesday, April 28, souvenir day on automobile row and banquet; Thursday, April 29, gymkana games, obstacle races, etc.; Friday, April 30, endurance run; Saturday, May 1, afternoon carnival parade.

Alex. Schwalbach, chairman of the endurance run committee, has named the following as the members of the committee: Herman Kuntz and C. F. Clarkson, A. L. A. M.; Alfred Reeves and L. M. Bradley, A. M. C. M. A.; E. L. Ferguson and H. C. Harbach, secretary, Quaker City Motor Club.

MINNEAPOLIS HAS NORTHWEST SHOW.

MINNEAPOLIS, MIN., March 15.—What is the greatest exhibit of automobiles ever held in the Northwest opened Saturday night in the Minnesota State Armory, and will continue throughout this week. The Minneapolis Automobile Show Association, an organization of local dealers, after having dropped out of the show business for a year came to the front this year with an exhibition which is the biggest kind of a success. Over 40,000 square feet of space was sold, and a score or more of tardy applications were turned down, because of the lack of space. Manager Walter Wilmot, the ex-big league baseball star, prepared things with a lavish hand, and the decorating and lighting schemes are elaborate and harmonious.

The entertainment features of the show this year surpass anything before attempted in Minneapolis. The First Field Artillery band, a celebrated national guard organization, gives concerts twice daily, and besides this a dozen artists, both vocal and instrumental, have been engaged. In addition to these attractions, there is continuous vaudeville in the portion of the ballroom, on the third floor, not been turned over to exhibitors.

BROOKLYN TO HAVE ITS FIRST SHOW.

BROOKLYN, N. Y., March 15.—This section of Greater New York will have its first individual automobile show, under the sanction of the Long Island Automobile Club, at the Clermont Rink from April 10 to 17, and the prospectus sent out by the managers, C. H. Green and E. J. Rowe, says that "it will be the most beautiful show ever held in America." The floor space has been divided so that there are thirty-one large spaces for exhibits of automobiles, and twenty-five for accessory booths. The large spaces average about 15 by 18 feet in size, and enough have been secured in options to show the interest taken in the event by Long Island tradesmen.

Packard 3-Ton Truck Used for Hauling Ice.

This truck has recently been placed in service by the Union Merchants' Ice Company, of San Francisco. This marks another branch of service to which the commercial car is being applied.

NEW BOSTON SALESROOM FOR PACKARD.

BOSTON, March 15.—Expansion of the local automobile trade beyond the bounds in which it has heretofore confined itself is indicated by the announcement just made by Alvan T. Fuller, agent for the Packard and the Cadillac, that he has purchased 87,500 square feet of land on Commonwealth avenue, near Cottage Farms, upon which he is to erect a building 300 by 70 feet, ground measurements, and five stories high, to contain his salesrooms, offices, shops and repository. Mr. Fuller for several years has been located in the Motor Mart in Park square, where he occupied a very large amount of space with his salesrooms and shops. His business has outgrown even these commodious quarters, and for this reason he is to erect the new structure.

The lot of land has a frontage of 271 feet on Commonwealth avenue, the principal automobile thoroughfare to the west of the city. It also has a frontage of 356 feet on Malvern street, 260 feet on Gardner street and is 304 feet long on the rear line. The frontage on the avenue is on a curve, which will give Mr. Fuller's establishment a conspicuous position. The building probably will be of reinforced concrete, and it will be equipped for making every part of an automobile.

ANOTHER ADDED TO YORK'S FACTORY.

YORK, PA., March 15.—The three plants at York now devoted to automobile manufacture will soon be augmented by the works of the New Departure Motor Company. This is a Western concern, with headquarters in Lansing, Mich. The head of the firm, J. C. Montgomery, has been in the city for several days negotiating for a site, and has practically decided upon the one he wants.

Upon this will be built a large modern plant, to accommodate 500 men. The output will be a lower-priced car, of which 1,500 will be turned out for the 1910 season. The principal product will be taxicabs, of which two-thirds of the output will consist, the other 500 being commercial cars. The principal office will remain in Lansing, the new works here being but a manufacturing branch.

MAXWELL PLANS 10,000-MILE NON-STOP.

In order to boost the non-stop run records as high as possible, the Maxwell-Briscoe Motor Company has determined to start a 10,000-mile non-stop test, using one of the four-cylinder 30-horsepower runabouts, and within a few days this will be started. It is probable that the first trips of the car will be in and out of Boston, covering the roads for many miles around that city, and, it is reported, an A. A. A. sanction will be asked, naming this as an endurance contest. Carl W. Kelsey will have charge of the performance.

WITHERBEE IGNITER MOVES TO SPRINGFIELD

SPRINGFIELD, MASS., March 15.—No sooner did the regulars in the vicinity of the New York Motor Mart discover that the Witherbee Igniter Company had something up its sleeve than there came from Springfield news to the effect that the company had taken possession of a large, modern brick factory building on Birne avenue, at the corner of Arch street, this city. With upward of 40,000 square feet of floor surface, in one of the most important automobile centers in New England, it is learned that the company proposes to cut loose with its highly specialized devices with a view to reaching a far higher level of production, hoping, perhaps, to ultimately keep pace with the demand.

The new plant is equipped with up-to-date machinery, and such apparatus as will facilitate in the processes by which the well-known Witherbee accessories are made. Among the new endeavors, under the most happy auspices, will be the pushing of Wico commutators, spark plugs, ignition wire, batteries and Volta magnetos. The general office of the company is now at the plant, in Springfield, but the Motor Mart quarters will remain the New York City branch office of the company.

'09 RAINIER CARS SOON DUE IN NEW YORK.

From the old factory of the Rainier Motor Company, which has resumed operations at Saginaw, Mich., the first of the 1909 models of the Rainier cars will be sent to New York, and will be shown in the new headquarters of the company at Broadway and Sixty-fourth street next week. Having acquired the rights, title, and interests of the Rainier Motor Car Company, the new corporation, with a capital stock of $350,000, has been duly registered at Albany, N. Y., and the production of Rainier cars will now proceed without interruption. The incorporators are Paul N. Lineberger, George C. Comstock, and Frederick H. Van Houten, and the management will be in the hands of John T. Rainier and Mr. Lineberger, the president and vice-president, respectively. In addition to taking the corner store for its metropolitan headquarters, the firm will have the entire top floor of the same building, with over 22,000 square feet of floor space, giving room for repair and paint shops.

At the Saginaw factory it is the Marquette Motor Company which is producing the cars for the Rainier Company. The Marquette company is capitalized at $300,000, and it is understood that it has the backing of the General Motors Company, in which Buick and Oldsmobile interests are merged.

ACME REVIVES OLD COACHING DAYS.

Over the same roads that many years ago were the routes taken by the mail and passenger coaches on regular schedules, in lumbering from New York to Philadelphia, an Acme limousine has now started on a regular service between the hyphenated hostelries of these two cities.

First Shipment of Cartercar Taxicabs from Factory.

The Cartercar Company, of Detroit, which has taken up the manufacture of taxicabs in addition to its regular line, is equipping these cars with the friction transmission, and the new chain-in-oil drive.

NEWS IN GENERAL

Cadillacs Arriving in London.

The illustration shows a shipment of Cadillacs from the Detroit factory to the London branch, which have just been unloaded from a transatlantic liner, and gives an idea of the company's increasing export trade.

Proper Tire Inflation.—Perhaps the first to recognize the special importance of proper inflation was Edouard Michelin, the well-known tire manufacturer, who is a skilled scientist and has made a life-long study of rubber and its peculiarities. Mr. Michelin once observed that, although over-inflation was a common fault, fully 50 per cent. of the tires tested at the Michelin factories and branches were insufficiently inflated. "Don't be afraid of bursting the tires," said Mr. Michelin, recently, "the tires will stand as much pressure as an ordinary tire pump can put into them." The air pressure in the tires should be proportioned to the weight of the car and its occupants, the size of the tires and the horsepower of the motor. A booklet issued by the Michelin Tire Company, Milltown, N. J., contains tabulated instructions for determining the proper tire pressure, and is of value to any car owner, regardless of what particular tires he may be using.

One Thousand Magnetos a Week.—With 4,000 magnetos sold on minimum specified delivery for March, and orders increasing rapidly, the Remy Electric Company, of Anderson, Ind., has decided to try to produce 200 high-tension motor ignition systems every day, the present capacity being about 1,000 per week. In addition to making equipments for automobiles the concern is rushed with work from stationary and marine-engine manufacturers and a number of magnetos are being built especially for the big gasoline motors employed by the Union Pacific and other western railways. New men have been added to the office and factory force, and educated in the building of magnetos as rapidly as possible, and new machinery is being installed as fast as it can be secured. The Remy Company claims that it is the first to ship magnetos in carload lots, as it has done recently.

Quaker City Also Has a Non-Stop Run.—Just as a sort of Quaker City annex to the main show in Boston, the Philadelphia Maxwell agents, the Longstreth Motor Car Company, started one of their little $500 "junior" runabouts on a 2,000-mile non-stop stunt last Saturday morning. Up and down Broad street and around the suburbs the compact little "junior" will plug away until its task is finished. Drivers will work in eight-hour shifts, and relays of observers have been arranged for. No attempt at speeding will be made, and the arranged-for 12-miles-an-hour schedule should enable the car to complete its journey in about seven days. On Wednesday evening the car had completed 1,000 miles.

Pennsylvania Racing Team Formed.—With the intention of being represented in all important automobile contests during the coming season, a racing team has been established by the Pennsylvania Auto Motor Works, of Bryn Mawr, Pa. Len Zengle, the young driver who piloted the cars in most of the events last season, will have charge and will have three machines, a six-cylinder stock car of 75-horsepower, which has a guaranteed speed of 85 miles per hour, and will be used in all open events, a 50-horsepower, four-cylinder car and one of the small ones, 25-horsepower, which will be used in their respective classes.

Cause of Tire Heating and a Preventative.—Although after a long day's run the tires become considerably heated up so that the warmth is noticeable to the hand, the cause for this is not well known. According to a Goodyear expert tire-maker this is the direct result of the frictional action between the outer shoe and the inner tube. It cannot be wholly avoided, but by rubbing French chalk over the tube before it is inserted in the shoe it can be materially reduced. The chalk acts to reduce the friction to a minimum, and therefore diminishes the amount of heat generated and the wear resulting from it.

Marion Cars Not Discontinued.—In final contradiction of the report which became general some five months ago, that the Overland Company had purchased the Marion plant, and that the latter make of cars would be discontinued, the Marion Motor Car Company has announced its intention of producing 400 four-cylinder cars during the coming year, of 35-horsepower, and in three styles, five-passenger touring cars, roadsters and toy tonneaus. The Marion Motor Car Sales Company, of Indianapolis, will have the sale of the entire output of the factory.

Anderson After Overland Factory.—The Overland Automobile Company and a committee representing the city of Anderson, Ind., are negotiating for the removal of the Overland factory to that town. It is reported that the company has signified its willingness to move providing the town furnish a factory site and a $60,000 cash bonus. The committee are reported as favorably disposed toward the proposition but the deal has not yet been closed.

Night and Day Work Necessary at York.—Busy is hardly the word to apply to the York Motor Car Company, of York, Pa., for it is even better than that. So great has been the demand for Pullman cars that a night shift has been a positive necessity. With the factory working twenty-four hours a day, the officials hope to catch up with the orders. The present plans include 100 more cars than were originally planned for this year.

Chicago Dealers' Ticket.—The nominating committee of the Chicago Automobile Trade Association, through its chairman, E. Q. Cordner, has named the following ticket for the annual election a week from Friday: For president, N. H. Van Sicklen, Sr.; for vice-president, H. C. Tillotson; for treasurer, Henry Paulman; for secretary, F. E. Sparks; for directors, Thomas J. Hay, E. Q. Cordner and Walter L. Githens.

Unit Coil Company Buys Patents.—The Unit Coil Company, of Jersey City, N. J., owner of the Varley and Williams unit coil patents, announces that it has recently purchased the Brigham and Lawton buck-proof coil patents, and also two basic master vibrator patents issued to Miller and Dow in 1904.

Pardington Moves Parkway Offices.—A. R. Pardington, second vice-president and general manager of the Long Island Motor Parkway, Inc., has announced the removal of the offices of the corporation from 527 Fifth avenue, New York City, to the Denton building, Mineola, Long Island, where they will be located in future.

Busy Overtime Making Sparks.—The K-W Ignition Company, Whitney building, Cleveland, reports that it is so pressed with orders that a night shift has become an absolute necessity. The big plant is therefore working night and day to keep up with the requirements of its customers.

IN AND ABOUT THE AGENCIES.

Hoyt Electrical Instrument Works, New York.—The Hoyt Electrical Instrument Works, of Penacook, N. H., has opened an office at 1931 Broadway, New York City, to facilitate handling of its export business and to take care of its trade in the territory contiguous to New York. R. V. Sutliffe, formerly superintendent of the Dayton Electrical Manufacturing Company, has been secured as branch manager.

Several KisselKar Agencies.—The Kissel Motor Company has announced the establishment of the following agencies for the KisselKar; Conucil Bluffs, Iowa, Bertschy Motor Company; Jacksonville, Ill., Dick Y. Rowe; Kankakee, Ill., E. A. Jeffers; Ashkum, Ill., Richard Meents; Ottawa, Ill., C. A. Miller; Bedford, Ind., A. E. Dickinson.

Warner Auto-Meter, Seattle.—The Warner Instrument Company, manufacturers of the well-known auto-meter, have just opened their fourteenth branch house at 914 East Pike street, Seattle, Wash. This office will be in charge of H. L. Worthen, recently connected with the Los Angeles branch.

Rambler, Hartford, Conn.—As a direct result of the recent show, Mansuy & Smith have signed up to handle the Rambler. This firm is the largest horse dealer in the city and for some time has been doing motor car work. The large place of business at 17-19 Elm street is well equipped for the purpose.

National, Chicago.—Charles P. Root, chairman of the contest committee of the Chicago Motor Club, and a prominent figure in Windy City automobile circles, has taken the agency for the National cars in that city, in addition to handling the Truscott motor boats.

Moon, Milwaukee.—The State agency for the Moon line of cars has been taken by the Riverview Automobile Company, which will move into its new garage, May 1. The latter is located at 325 East North avenue, and is one of the most up-to-date in the northwest.

Winton, Cincinnati.—L. C. Denison, of Cleveland, has secured the Winton Six agency for Cincinnati and opened for business, March 15th, on Ninth street, between Vine and Sycamore, in premises lately occupied by the Cincinnati National Bank.

Chalmers-Detroit, Grand Rapids.—The Imperial Auto Company have received their 30 horsepower demonstrator and are busy exploiting the merits of the Chalmers-Detroit, for which they have taken the local agency.

Oldsmobile, Milwaukee.—The Olds Motor Works of Lansing, Mich., has established a branch in Milwaukee, with temporary headquarters with the Excelsior Motor Car Company, 621 Grand avenue, that city.

Brush, Hamburg, N. J.—An agency for the Brush runabout and delivery wagon has been established in Sussex County, N. J., with Reeve Harden, of Hamburg.

Ford, Fond du Lac, Wis.—P. B. Haber has been appointed agent for the Ford line at Fond du Lac, Wis., and surrounding territory.

Lozier, Wisconsin.—Willard V. B. Campbell, of Horicon, Wis., has been appointed State agent for Wisconsin of the Lozier.

E-M-F, Morristown, N. J.—Willard B. Smith, of Chatham, has been appointed agent for the E-M-F in this city.

Apperson, Milwaukee.—The American Automobile Company has taken the agency for the Apperson line.

RECENT BUSINESS CHANGES.

Chicago Trade Changes.—The tendency on the part of Chicago dealers to extend the row to the south has become even more pronounced, and last week it was announced that two more of the agencies would move from their present location in the heart of the row to the southern part of the line, where already the Stearns and Packard have secured sites. H. Paulman & Co., Chicago representatives of the Pierce-Arrow, now at 1430 Michigan avenue, have secured a lot 50 by 187 feet at 2420 Michigan avenue, where will be erected a two-story building which will be ready for occupancy by June 15. The Locomobile branch, now at Michigan avenue and Fourteenth street, has leased property 75 by 171 feet at the southwest corner of Michigan and Twentieth street, and will build a three-story building of concrete and steel.

A. M. C. M. A., New York.—New and more commodius headquarters were last Monday occupied by the general offices of the American Motor Car Manufacturers' Association, on the fifteenth floor of 505 Fifth avenue, New York, half a block from the former office at 29 West Forty-second street.

Rutherford Rubber Company, New York.—The Rutherford Rubber Company, manufacturer of Sterling tires, has removed its headquarters from 253 West Forty-seventh street to Broadway and Fifty-third street.

Dow Tire Company, Boston.—The Dow Tire Company announces that its Boston office is now located at 893 Boylston street.

PERSONAL TRADE MENTION.

Some Ajax Trade Changes.—More changes in the Ajax-Grieb Rubber Company's sales forces have been announced. H. M. De Silva, who formerly traveled for the factory through the western territory, has been installed as manager of the Chicago branch. Leon B. Smith has been succeeded by Joseph S. Gibbs as manager of the New York branch, and the latter will have charge of the New York and Connecticut territory.

A. Eugene Michel has just opened new offices at 1572 Hudson Terminal Buildings, New York City, where he will act as advertising engineer for the promotion of automobile accessories, steam apparatus, power transmission appliances and machine tools. Mr. Michel is a graduate engineer, Associate Member of the A. S. M. E., and has had eleven years of advertising and engineering training.

Bertram Bailey, formerly general manager and engineer of the Tour Traction Auto Company, of Mankato, Minn., has resigned from that position to accept one as chief engineer of the Schurmeier Wagon Company, of St. Paul and Minneapolis.

OBITUARY.

Henry Bausch, of the Bausch & Lomb Optical Company of Rochester, N. Y., died in Augusta, Ga., on March 2, where he had been since early in January for his health, his illness lasting for nearly a year. Mr. Bausch was the third son of J. J. Bausch, who, with Henry Lomb, organized the immense optical plant which bears their names, and in which Henry Bausch has been actively interested and engaged since 1875. He is survived by Mrs. Bausch and one daughter.

RECENT BUSINESS TROUBLES.

Pneu L'Electric Company, New York.—Schedules in bankruptcy of the Pneu L'Electric Company, dealers in automobile supplies in New York City, have been announced, showing liabilities of $31,338 and nominal assets of $12,856, consisting of stock, $3,000; accounts, $9,082, and cash on hand, $774.

NEW TRADE PUBLICATIONS.

Ferro Machine & Foundry Company, Cleveland, O.—This is not a catalogue, as an extensive general catalogue is published separately, but is really a text-book for owners and operators of marine engines. Realizing the fact that so few people owning or interested in marine engines really understand the construction and operation of the motors thoroughly the Ferro company, the large marine engine builders, publish each year "A Practical Treatise" on the subject. The 1909 "Treatise" is the most exhaustive work ever published on the subject of marine gasoline engines. It tells in simple language and with the aid of more than 300 illustrations all about the construction, installation and operation of these motors. The book is compiled by some of the most practical motor experts in the country and is something every one interested in marine engines should have.

Trenton Rubber Mfg. Co., Trenton, N. J.—One of the neatest and most attractive bits of advertising literature that has come to hand recently is the product of the advertising manager of the Trenton Rubber Mfg. Co., makers of Thermoid brake lining. It is in the interest of this that the book is sent out, but one would have to search it through several times to find the advertising portion, so cleverly is it hidden. The book is 8¼ by 11 in size, large enough for an excellent series of pictures, and the title is "The Automobile of 1909." Following the attractive frontispiece in colors, which shows a beautiful female bather ankle deep in the surf over the caption "A critical inspection invited," are illustrations of some forty motor cars with detailed specifications. The latter occupy the right hand pages of the book, while upon the left hand and facing the cars, are various beautiful and interesting scenes. These are not confined to any one section of the country, but are selected at random from the best the country affords. The only trace of advertising which mars this beautiful work from the point of view of the art connoisseur is the simple statement that each car uses Thermoid brake lining. It is a very effective piece of catalogue art.

Car Lot of Remy Magnetos Ready for Shipment from Factory.

The photograph shows a car being loaded at the factory of the Remy Electric Company, Anderson, Indiana, with high-tension magnetos for shipment to Eastern automobile factories. The Remy shipping department states that several carloads of magnetos and coils with special parts are shipped every month.

INFORMATION FOR AUTO USERS

Little Giant Air Compressors.—Every garage has a need for air in some form, it may be used to inflate tires, for starting stationary gas engines, for operating heating and brazing machines, for pneumatic tools, sand blasts and many other every-day purposes. In order to have air pressure for these purposes, a first-class compressor is a necessity. The Orange Machine & Mfg. Co., 10-14 Statson street, Orange, N. J., has brought out the Little Giant to meet this need. This is a small and inexpensive machine built in a thorough, workmanlike manner, the small details being given a maximum amount of attention. It may be arranged for direct connection to a revolving shaft or can be belt-driven. The makers not only furnish the compressor, but the storage tank, piping, etc., so that a complete outfit may be obtained from them if desired.

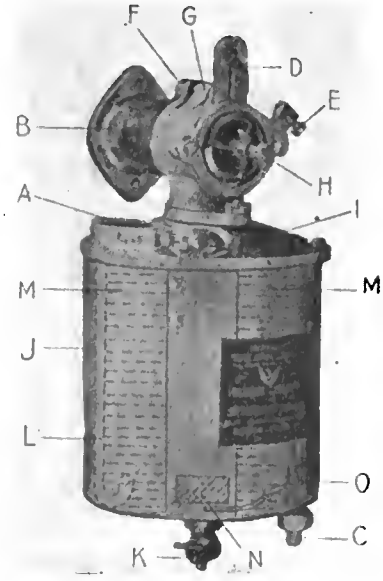
LITTLE GIANT AIR COMPRESSOR OUTFIT.

Simms Magneto Switch Starter.—Now that magnetos have become deservedly popular, and well nigh universal, some form of a starting device is almost a necessity. The makers of the Simms magneto have come to the front with such a device and automobilists will doubtless welcome it with open arms. This has a special contact-breaker on the magneto, the switch starter on the dashboard and an ordinary accumulator.

SIMMS DASHBOARD STARTING SWITCH.

Aside from these, the equipment is exactly like any other magneto outfit. The contact breaker is so designed that the points are normally separated, causing the armature primary circuit to be opened rather than closed. Then, by means of a special switch, a make-and-break current is instantly passed through the primary winding, a very quick break causing an intense spark, which invariably starts the engine. After being started this runs on the magneto in the ordinary manner. Albert R. Miller, 42 Broadway, New York City, is the sole American representative of the Simms Magneto Company.

Triple Action Carbureters.—The woods are full of carbureters, some good, some bad, and some, neither the one nor the other. The Triple Action just brought out by the American Carburetor & Improvement Company, 1660-1668 Bushwick avenue, Brooklyn, belongs in the first class, and has the additional distinction of being different, that is, it works on a different principle. This device has no needle valve to regulate and practically no float:



DETAIL OF TRIPLE ACTION CARBURETER.

that is, there is a very small metal float but it is used for a different purpose than the ordinary. In the cut is shown the barrel-shaped portion which forms the body of the Type M carbureter. This is marked J and contains a series of concentric plates M, spaced just enough to make room for the spray tubes L. In the center is formed a round chamber, which leads to the mixing valve. The last, which is also the throttle, is mounted above the other chamber, and carries two adjustments. The first of these is for slow and the other, for high speeds. F is the regulating screw for the former and H, for the latter. The position of both is one that gives ready accessibility. In action, the gas enters at the bottom and is gasified by the air passing upward through it from the multitude of air tubes L. The plates are so arranged that a uniform quantity of gas must pass between them for their entire height before it can enter the central gas chamber. This rich gas is mixed with the proper quantity of air at the aforementioned valves and passes thence directly to the inlet pipes. Hot air from the exhaust pipe may be led in if desired at A. The float valve is seen at O, just above the gasoline inlet C. At K is the drain cock and all other parts are self-explanatory.

Auto Cap Purse.—The Gloversville Purse Company, Gloversville, N. Y., are bringing out a novelty in the line of leather purses intended primarily for automobilists. This is called the auto cap purse from its resemblance to the ordinary leather cap, but is a practical purse for coin or bills. These purses are made in a variety of leathers and colors. The large, flat surface of the top gives a space for letters, names or advertisements. The purses can be stamped in gold or colors which in combination with the novelty of the shape makes a very attractive article.

AUTO PURSE RESEMBLING A CAP.

The Auto Wind Shield.—As the illustration depicts, the device answering to the above title differs from wind shields in general, in that the driver looks over, and not through, the transparency, which is celluloid in this case. The shield is of a suitable grade of water-proof fabric, stretched over bows just as a cape top is fashioned, and besides warding off the wind and dust, which is deflected above the head of the driver, the shield keeps out the cold and the rain as well. Every autoist knows how futile it is to try to keep lap robes in place in such a way as to ward off the wind.

The shield puts an end to all the mechanicians of the wind and harbors the lucky autoist in a manner quite in keeping with the needs, which are indeed strenuous under certain conditions of inclement weather.

The wind shield fits closely around the driver's seat, buttons into place with but small effort, and folds back out of the way when it is desired to enter or leave the seat. It is a neat device, made strong, to withstand hard usage, and it in no way "badgers" the looks of a well designed automobile. The cost is very low indeed, considering the great utility of the shield, and the Auto Wind Shield Company, of Brattle Square, Cambridge, Mass., is to be congratulated in having invented and patented this excellent shield, the demand for which is so very brisk as to tax the facilities of the company to the utmost.

NEW TYPE OF WIND SHIELD.

VOL XX NEW YORK—THURSDAY, MARCH 25, 1909—CHICAGO No. 12

THE AUTOMOBILE

FLORIDA'S SPEED CARNIVAL HAS A VARIED FIELD

By R. F. Kelsey

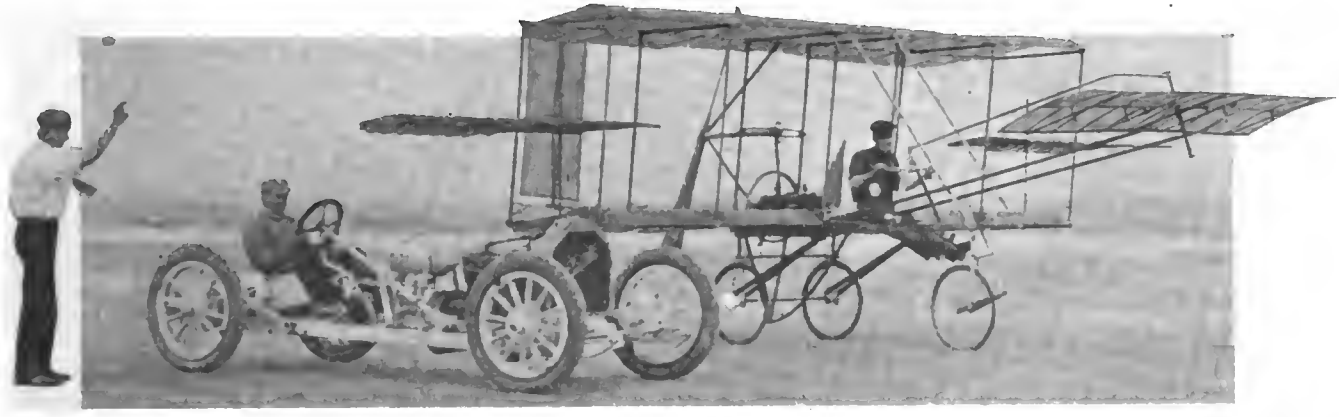
DAYTONA, FLA., March 22.—Varied in character, yet withal interesting, the Florida meet promises a substantial success, conducted as usual under the auspices of the Florida East Coast Automobile Association, with W. J. Morgan, the originator of the series, the man at the helm, though this time with headquarters located entirely at Daytona.

The program includes automobiles, and motorcycles, and bicycles, not forgetting the presence of a real aeroplane.

Monday, while in practice on the beach, H. J. Kilpatrick, whose Hotchkiss racer is entered for all the high-powered car events, threw a wheel. Kilpatrick sustained no injury, but the accident prevented further practice work by the machine to-day, as it took considerable time to make repairs.

Referee S. A. Miles was on the ground early, and is doing yeoman service in assisting in the completion of the preliminaries. "Senator" Morgan is displaying his characteristic energy in arranging the details, and imbues every one with enthusiasm. He is ably assisted by Alex Schwalbach, who is looking after the press and its representatives. Fred J. Wagner, the veteran clerk of the course and starter, is as usual at the post of duty, alert and watchful.

Representatives of the trade are quite numerous from the



In the afternoon the motorcyclists were out in full force, Oscar Hedstrom with a new Indian machine of about ten-horsepower creating a sensation with his phenomenal burst of speed. Fred Hill, of Boston, who is after professional honors for the U. S. U., also reeled off some miles well under the minute mark. Among the amateur motorcyclists who are present for the races, are A. G. Chapple and Walter Goerke, of Brooklyn: Robert Stubbs, Birmingham, Ala.; William Wray, Jr., and Eugene Gaestel, New York. President Earl Ovington of the Federation of American Motorcyclists will officiate as referee for this class of events.

Many prominent racing cyclists are entered for the cycling events, including E. L. Collins, Joseph Fogler, George Wilcy and E. F. Root, and will compete for the mile record, paced by Robertson in the Benz, and De Palma in the Fiat *Cyclone*. They will also be paced by motorcycles in a separate series of trials. A bad fall in a motor-paced race at Atlanta last week prevents the attendance of R. A. Walthour, who was entered.

North, and among those who have arrived are A. M. Mayo, of the Fisk Rubber Company of Chicopee Falls, Mass.; W. B. Wise, Flint, Mich., sales manager of the General Motors Company; Ralph Pope, manager of the Cleveland Automobile Company; W. H. Pickens, publicity manager for the Buick; Inglis M. Uppercu, president of the Detroit-Cadillac Motor Car Company, of New York City, and the Motor Car Company of New Jersey. Leonard D. Fisk, the Hartford, Conn., representative of the Locomobile, is also in attendance, as are "Doc" Maxwell, publicity manager for the Benz Import Company, and J. Wilbur Hobbs, the Michelin tire representative. Others are known to be on the way.

Carl Bates, the aeronaut, has his aeroplane tuned up and has made a few practice flights successfully. He is expecting to

Strang and Burman Talking with Aeronaut Bates.

make good here, and one match race may be between his aeroplane and Strang in an automobile. Bates is confident.

Three World's Records on Tuesday.

DAYTONA, FLA., March 23.—Three new world's records, one professional and two amateur, were the result of the opening day of the Florida East Coast Automobile Association's seventh annual meet. The most sensational performance was that of David Bruce Brown, who lowered the world's amateur record for the mile to 33 seconds, a rate of over 109 miles per hour, in the trials for the Sir Thomas Dewar trophy. He drove Hugh McIntosh's 120-horsepower Benz racer, with which Hemery finished second at Savannah. In the other two of his three attempts, Brown's times were 33 1-5 and 33 2-5 seconds. The Fiat *Cyclone*, driven by Ralph De Palma, was the only other competitor, and his best time was 36 seconds, which was considered good, in view of the 60-horsepower.

Monday's high winds put the beach in fine shape, but made the tide high, and inasmuch as the race to-day was late in starting, it was necessary to cut the 200-mile event to half that distance. This race brought a Cadillac, driven by Herbert Lytle, and three Buicks, driven by Burman, Strang, and Dewitt to the tape. Dewitt had a Baby Buick, and was in a separate class, running at the same time. Burman led the first round of 20 miles, in 18 minutes 17 seconds, but on the second lap he lost his carbureter, and was cut out of it. Strang took the lead and held it to the end of the race, 100 miles, the high water then calling a halt. His time was 1 h. 34 min. 1 4-5 sec., breaking Burman's 100-mile record of 1:42:26, made last month at New Orleans. Dewitt, of course, won his class, as he was the only competitor, his time being only ten minutes more than Strang's, 1:44:34. Strang's intermediate laps were: 40 miles, 36:56 4-5; 60 miles, 55:02; 80 miles, 1:15:20 3-5.

Walter Goerke, of Brooklyn, captured the honors in the motorcycle time trials for the mile, making a new amateur record of 45 1-5, by breaking the former record of 46 2-5.

Eventful Happenings on Wednesday.

DAYTONA, FLA., March 24.—A magnificent beach and a wind-straight-up course was productive of records galore to-day. Two of these—the five and ten-mile events—went to Hugh McIntosh's Benz. In the five-mile invitation race George Robertson drove, winning in 2:45 1-5 from the Fiat *Cyclone*, breaking both the steam and gasoline car records for that distance. In the ten-mile free-for-all Bruce Brown drove, winning from the Fiat driven by De Palma in 5:14 2-5. The Fiat made a close run, with half the horsepower, 29 4-5 seconds separating them.

In the motorcycle record trials Walter Goerke made a new amateur record for two miles, 3:30 1-5. The Southern five-mile price handicap was won by a Pope-Hartford car, with a Cleveland second and a Locomobile third. Fogler won the half-mile bicycle race in 47 1-5 seconds, setting a new record, and he also won the two-mile race in 3:45 1-5.

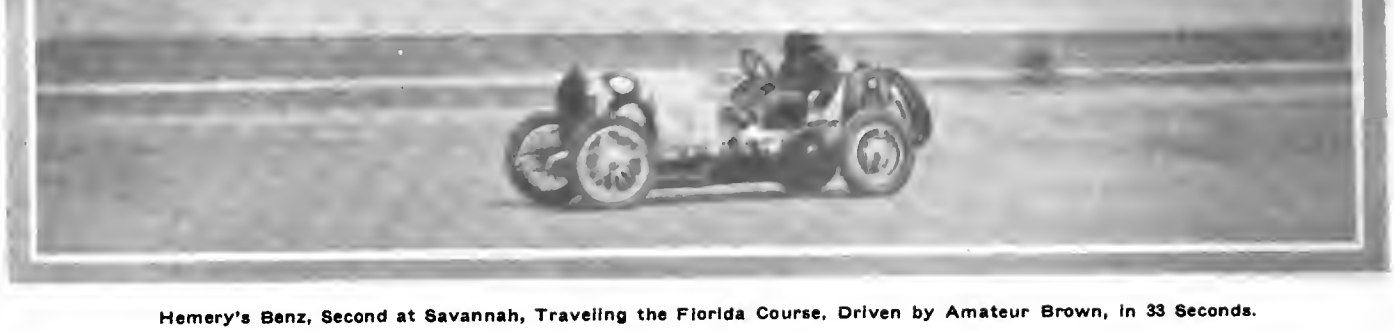
Darkness and a fast incoming tide soon made it clear to Referee Miles and the others present that the 200-mile piston displacement race, which had been started rather late, would not be finished, so when conditions made it absolutely necessary, the cars were flagged. There were three starters in the class, for cars with over 400 cubic inches displacement, and when the leader, De Palma, in the Fiat *Cyclone*, was stopped he had covered 120 miles in 1:33:44 3-5. The Benz racer, driven by Robertson, broke a piston soon after the start and had to withdraw. Strang, the third starter, in a Buick, stopped after going 100 miles when he was in second place.

The phenomenal five-mile record made by Brown broke those held by Marriott, in a Stanley, for steam cars, of 2:47 1-5, and that made by Lancia, in a Fiat, for gasoline cars, of 2:54 3-5.

GRINNON LEAVES SAVANNAH HOSPITAL.

SAVANNAH, GA., March 22.—After many months of inactivity, an aftermath of the Grand Prize Race, Joe Grinnon, who was seriously injured when Burman's Buick car was smashed in the practice for the International Light Car Race, riding as the driver's mechanic, has just left the Savannah hospital to go to Daytona. Although still unable to do any work he has been attracted to the Florida beach by the reports of fast practice, and to see the races. It is said that it will be more than a year before his arm will permit him to do anything but the lightest kind of work.

Chatham county road commissioners now have two highways under consideration, one to Beaufort, S. C., a distance of 60 miles, and another to Tybee, Ga., 18 miles. Both have been indorsed by the merchants and the city officials. It is probable that the county will commence work on the road to Beaufort first, as the one to Tybee has been put up to the government to build. At Tybee there are more than a thousand soldiers, and the only means of communication is by railroad.



Hemery's Benz, Second at Savannah, Traveling the Florida Course, Driven by Amateur Brown, in 33 Seconds.

Picking the Route for the Coast-to-Coast Contest

STARTING FROM THE HOTEL ASTOR

CALLED AT CITY HALL FOR MESSAGE

STOPPED AT THE A. C. A. FOR A FLAG

CONVEYED to the city limits by enthusiastic New York automobilists, the Thomas car, which won the race from New York to Paris, last Saturday afternoon commenced another long, arduous trip, in laying out the route for the contest which will be held this Summer from coast to coast, starting in the metropolis and finishing in Seattle. Driven by George Miller, who was the mechanic upon the car in crossing Europe and Asia, with C. W. Eaton as his mechanic in the new venture, J. S. Sley representing the Thomas company, and L. W. Redington as official pathfinder, representing Mills and Moore, under whose management the event will be conducted, the car was given a rousing send-off wherever it appeared in the metropolis. In preparation for the transcontinental run, the machine was slightly changed from its former self, by the addition of a wide seat at the rear, but in general the equipment is the same that it carried around the world, even to shovels, ropes, and tackle. Of course, some 'round-the-world mud was missing.

And when Miller waved good-by to his escort, the first part of what promises to be a contest of widespread interest was begun. In the morning the party, including Edwin L. Thomas, the present acting head of the Thomas factory, went to the City Hall, where they were tendered an informal reception, and given a letter from Mayor McClellan to the Mayor of Seattle. Finally, emerging from the immense crowd surrounding the car, it was driven to the Hotel Astor, where W. H. Hurlburt, the recently appointed manager of the local Thomas branch, gave a luncheon to the crew, and others involved in the run.

At half-past two in the afternoon, preceded by a Zust car, given the position as leader as a compliment to its being a competitor, and a finisher, in the race to Paris, the big car started, and its escort fell in behind them. All of the machines were gaily decorated with flags bearing the letters "A. Y. P.," standing for Alaskan-Yukon-Pacific exposition, on account of which the run will be held. The first stop was at the Automobile Club of America, where Robert Lee Morrell, representing the club, presented the crew with a flag, admonishing them to carry it safely across the continent. Continuing up Broadway a great deal of interest was manifested along "Automobile Row," and a number of the cars, including the Zust, stayed with the Thomas as far as Yonkers, where a final farewell was said.

Poughkeepsie was the stop on Saturday night, after an uneventful run, and arrangements made with a hotel to sign the cards of the cars which will start from City Hall, New York, on the first day of June. Sunday was spent in running from Poughkeepsie to Little Falls.

From Little Falls to Syracuse, the itinerary on Monday was one continual reminder of the start of the race to Paris last Winter, for the snow was deep and heavy, and for 100 miles the car had to plow through drifts, and seek its way along poorly marked roads. Batavia was reached on Tuesday evening by a fast run of 160 miles, and Miller and his party wanted to push on to Buffalo, but on account of a prepared celebration, waited until Wednesday morning. A short trip took them into the Thomas' home town, where every one vied with one another in greeting the tourists, who will keep the usual route to Chicago.

The Stock Chassis

CHICAGO, March 22.—The trophy offered to the American Automobile Association by Ira M. Cobe, president of the Chicago Automobile Club, for a national stock chassis race has been withdrawn, and, instead of promoting a national event, the club has decided to put on a Western stock chassis race, the cup for which will be given by Mr. Cobe. At the present time, Mr. Cobe is preparing a letter, to be sent to the A. A. A., in which he will outline his reasons for withdrawing the trophy as a national event, and which had been accepted as such at the meeting in Boston during the show. The contention of the Chicagoan is, that one of the clauses of his deed of gift provided for the national race being run within 50 miles of Chicago this spring, but that it is impossible to carry out this provision because no one in Chicago is willing to undertake the promotion of such an event, because of the restrictions.

Chairman Hower's visit to Chicago last week brought matters to a climax. When the race was first broached here few understood what it meant to run a national road race, so all were enthusiastic over the proposition. The route had been picked, entries solicited, an organization perfected, and it looked as if everyone would work hard for the success of the event. But when Chairman Hower came on and explained that it was to be an A. A. A. event pure and simple, and that the national organization would control it all the way, there came a change of opinion. The local workers objected to doing all the preliminary work, such as financing the race, preparing the course, building the grand stand and the like, and then dividing profits with the A. A. A., letting it name the officials, make the rules and take the credit. Some of the executives chosen by the local club balked, refusing to work under such conditions, and the directors of the club themselves could not see any possible benefit to be derived from such a partnership. Therefore Chairman Hower was requested to come on and talk it over.

Several sessions with the chairman of the contest board were held, the deciding one being held last Thursday, at which time it practically was decided to give up the idea of running a national race. On Friday decisive action was taken, President Cobe looking at the matter in the same light as did his colleagues on the board, and by a unanimous vote it was settled that the Chicago Automobile Club should not undertake the promotion of the Cobe trophy national stock chassis race. Instead, Mr. Cobe announced that he would withdraw his deed of gift, and hang up a cup to be competed for in a Western stock chassis race, which the club would put on.

Following this decision the directors and the contest board discussed the plans for the Western derby. It was held that May 29 and 31, the dates selected for the light car race and the Cobe event, would not do, because of probable unsettled weather and the desire for better road conditions. Also, little more time was needed to perfect the organization. Therefore, the board changed the dates to Friday and Saturday, June 18 and 19. On the first day will be run a race for light cars at probably 200 miles, while on Saturday the main event at about 400 miles will take place. As soon as the necessary formalities, such as providing for the guarding of the course, and the securing of the permits to use the roads are taken up, an application for a sanction will be made to the contest board of the A. A. A. Chairman Hower has promised to push through the rules as soon as possible, going from here to Detroit, where he had a conference with H. E. Coffin, chairman of the rules committee of the Manufacturers' Contest Association. Piston displacement will be used in dividing the fields, but as to what the figures will be, is not known as yet.

The announcement of the decision to run a Western road race stirred to enthusiasm many members of local organizations, and as a result of this there was a joint run of the Chicago Automomile and Chicago Motor clubs last Sunday, the combined forces making the trip to Crown Point, in the vicinity of which is located the course, over which it is proposed to run the two races. Fifteen cars were in the run and a critical examination of the circuit was made. A subsequent canvass of the drivers and passengers revealed a great deal of favorable sentiment.

Starting from Crown Point, it was found that the circuit branched a trifle to the southwest, there being several bends and turns in the 5-mile stretch between the Hoosier Gretna Green and Cedar Lake. One of these is a spectacular S which will have to be negotiated with care. At Cedar Lake the course straightens up and runs 6 miles straightaway to the little town of Lowell. Going into the village, the entrance upon the main street is made through a narrow opening between two buildings. It is a square corner and the cars will have to slow down. It is the one bad spot on the course. From Lowell east about 3 miles, is the south leg of the course, where the highway is broad and smooth, and instances are known where one car has passed another while

going at 70 miles an hour. The east leg of the circuit is perfectly straight and is about 10 miles in length. There is here a 3 1-2-mile stretch of new road which, however, will be in prime shape by June. On this leg will be located the start and finish, the committee having picked out a location for the grand stand, about 1 mile from Crown Point

There are eighteen turns in all on the course, fifteen of which are left-handed ones. The road itself is stone the entire distance of 24 1-2 miles; there is not a single railroad crossing on the circuit and but two towns. Crown Point will permit the racers to go through, and so enthusiastic are the residents that they will, in all probability, consent to the streets through which the races pass being boarded up and a bridge erected over which it will be possible to get inside the course.

Entries are assured by so many concerns and individuals that there is more danger of there being too many cars nominated, instead of too few. Thomas, Knox, National, Locomobile, Palmer & Singer, Apperson, and many other makes are known to be looking forward to competing.

DETROIT GETS THE START OF THE GLIDDEN TOUR

DETROIT, March 22.—Detroit has won, and Detroit automobilists are justly proud of the fight which they put up in securing for this city the start of the annual tour of the American Automobile Association, for the Glidden and other trophies. Upon the Detroit Automobile Dealers' Association fell the brunt of the task of convincing those who decide upon the route of the contest that this city should be honored with the beginning of the great national event, but it was ably backed up by the Manufacturers' Association, the Board of Commerce and other organizations, and last, but not least, by the promise of fifteen entries for the tour. Headquarters will be at the Hotel Pontchartrain.

Holding the undisputed title of the "Center of the World," in the automobile industry, and never having been visited by the Glidden tour, the manufacturers and dealers of this city banded together to secure the start, and Chairman Hower has agreed that the cars shall line up on the Campus Martius, when they start, about July 7. In addition to the promise of fifteen entries, the fees, $3,000, have been actually paid by President Lane, of the D. A. D. A., this city will also furnish the pathfinding car and the pilot car, the E-M-F factory offering this inducement, in order to get the tour to commence its trip across half the Continent, from the "City of the Straits."

The fact that Detroit will be the start, is practically the only point in the preparations for the tour that has been definitely decided upon, except that Dai H. Lewis will leave here in the E-M-F pathfinder on April 1. It is known, too, that he will direct his course to Chicago, where the tourists in the summer will be royally received, but as to the route beyond that point there is no information forthcoming, and it is admitted that the Contest Board is in somewhat of a quandary itself over the matter. There is little doubt but that Denver will either be the final checking station, or be an important one en route. If it is the former, it is possible that Minneapolis will be included on the itinerary, and autoists from that city point out its many advantages as a Sunday stopping place, with Minnehaha Falls, Minnetonka and Lake Calhoun, whereas if Denver is not the final destination, it is possible that Dai Lewis will wend his way straight across Iowa, through Omaha to Denver, and then back to Kansas City, visiting Colorado Springs en route.

The most troublesome point is to get accommodations for the tourists, and Chairman Hower and his assistants are trying to solve the problem with the aid of a service of Pullman sleeping and dining cars.

It is felt here that even more than fifteen cars will be entered from this city and vicinity, for the E-M-F Company promises three, the Cadillac and Chalmers-Detroit will probably send three each, the Regal is considering the rules, the Ford Company is sometimes said to be thinking seriously of putting its little four-cylinder machines in the tour, and the Olds Motor Works is sure to enter three. The Buick, Jackson, Welch and other factories are still to be heard from. The Packard Company will probably have Ralph Estep and Tom Fetch out with a press car.

Is Road Racing Near Its Conclusion?

By W. McKean White

EVER since the first automobiles were constructed, even when they were in very uncertain stages of development, there has been perhaps no phase of automobile affairs which has elicited such widespread and general spectacular interest, both in Europe and America, as automobile racing, the high speed of big-powered cars being a subject of interest at all times. The question is still extant, but the answer is not; and in the present chaotic condition it certainly appears as if road racing, at least, were nearing a conclusion.

There is a wide difference of opinion as to whether a continuation of this form of extending the interest in motor-driven vehicles is advisable and economical or not. But that is not the problem at present, for there are enough manufacturers, dealers and owners of automobiles who enjoy racing from the purely sporting viewpoint and who believe in it from a business standpoint to make a success of it. At the same time, both in this country and across the Atlantic, there are certain manufacturers who do not race and who do not want their competitors to do so, and, moreover, are strong enough to throw a very serious obstacle in the way of speed contests. Still another condition exists, for certain large makers, composing a majority of entrants in most of the big events, in recent contests beaten, decline to enter further and have caused a number of big events of international character to be postponed for this year or permanently abandoned.

In the United States this sentiment has not been so strong, but there has been another cause that has brought trouble. So few agree upon proposed rules that it has been impossible to frame regulations for contests, and this has caused events to be practically dropped. Summed up, it is more or less a question of rules in this country. As to who shall interpret the rules, and have final jurisdiction and national authority over the events, has been settled by the formation of the Manufacturers' Contest Association and its alliance with the A. A. A.

The conditions in France, the nation whose manufacturers in the past few years have led in building special cars for racing, have kept expensive drivers, and have spared no expense in promoting and holding the meets, which drew to them the interest and patronage of the world, calls for comment. French cars held premier honors until the past two years, when Italian makers came very strongly to the fore, taking first place in a number of exceedingly important races. Then the Germans regained some of their former supremacy. The Grand Prix, won by the German Mercedes, disheartened the French; the Florio Cup race, appropriated by Nazarro in the Italian Fiat, was another blow; the Four-Inch race in England, taken by a Hutton car, wasn't encouraging, and, finally, the French hardly figured in the Grand Prize at Savannah. Then it was that a number of prominent French makers decided to combine for the "common welfare," first having the rules for the 1909 Grand Prix made with the stipulation that there should be forty entries at the beginning of the next year. When these did not appear, as it was planned, that great international race was declared off.

It is generally known, now, that at least seventeen firms, the majority French, were in the agreement and bound to one another so firmly that any one dropping from the number would have to pay a heavy forfeit. Those in the combination were: Dietrich, Germain, Motobloc, Berliet, Leon Bollee, Panhard, Renault, Brasier, Bayard-Clement, Delauney-Belleville, Isotta-Fraschini, Minerva, Pipe, Darracq, Peugeot, Mercedes and Benz. At least five other prominent concerns were asked to sign, but would not, being Mors, Fiat, Itala, Opel and De Dion. These were ready to take part in any good races. Although the whole autoing world fully expected to see this come about, it was nevertheless startled by the action in race-loving France. Inasmuch as these manufacturers in the agreement would not build any special cars this season, the Florio Cup race, proposed for the Bologna circuit, was promptly dropped, and the whole aspect of the situation became uninviting.

This situation has extended to this country to a large extent. In 1908 there were 21 American road races, with 199 entries. Of these one was international, one a free-for-all, without any limitations of consequence, several were for stock chassis, several more were cross-country races with no prepared course, and the remainder were class races, in which machines of some certain price, size or other characteristic were admitted.

Plans outlined for the coming season show that at least one international race may be put upon the calendar, the second contest for the A. C. A. Grand Prize cup, and it may be again held at Savannah. Hardly any one knows what will become of

the once blue-ribbon race, that for the Vanderbilt cup, nor, for that matter, whether there will be one for the Briarcliff trophy. Two stock car races of prime importance are even now being arranged, that in Fairmount Park, Philadelphia, and the other for the Cobe trophy, to be run near Chicago. Lowell, Mass., had a successful stock car contest last year, and sometimes there is an echo there as if another one would be acceptable. There is a vague report that Suffolk county, Long Island, is looking for a course and wants a race.

To be sure, this does not consider track or beach races, confining itself to those held upon public highways set aside for the purpose. The condition in this country, deep down beneath the surface, is not far different from that in Europe, except that here it is not a question so much of different countries as of different manufacturers within the country. For some time racing affairs have been in a turmoil, so that even if races were wanted it was almost impossible to hold them with any unopposed sanction. It was after the A. A. A. and the A. C. A. had apparently buried the hatchet and the hammer, and settled upon a definite line of joint action, that the manufacturers themselves formed the Manufacturers' Contest Association.

It should be understood that the popular wish for road racing is not declining, and the clubs so much realize such to be the case that at present two notable organizations, the Quaker City Motor Club and the Chicago Automobile Club, are making plans for their big events.

But even they are apt to run up against a very serious snag in the definition of a stock car, just as did the hold-over Briarcliff committee, though perhaps with less disastrous results. However, there will be a goodly number of makers to enter both contests. At the same time there are many who wonder what kind of race will be held for the Grand Prize, for there are no cars being built which will conform to the so-called 1909 international rules, limiting the bore of cars in international contests to 130 mm.—5.1 inches. The big cars which took part last year have a bore one inch greater than that. Unless something can be done, either to get the use of last year's rules, or to get cars for the new ones, it is likely that road racing under "international" rules is near a conclusion. Even in the stock car races it is probable that the bore of the engines will be allowed to go slightly beyond 5.1 inches, perhaps to 5 1-4 or 5 1-2, but the stroke may be limited, or still another opening is secured through the use of a piston displacement sliding scale, so that designers may use almost any bore and stroke they desire, just so the total displacement remains under a certain limit.

The Long Island Motor Parkway is being continued, but little is heard about the Vanderbilt race, and it is hard to make any prediction about that event. So that it can be seen that instead of twenty-one road races in this country during the coming season, there are just three positively scheduled after one-quarter of the year has passed. There will undoubtedly be some kind of a race at Savannah, and it is likely that something will be raked up to take New Yorkers out to familiar scenes around Garden City, Jericho and the parkway. This will give, then, only four high-speed contests. At the same time endurance runs and reliability contests are increasing in number, and it is not at all unlikely that last year's figures of 29 runs with 676 entries, will be exceeded. Still another prospect appears, that of increased track racing over courses built especially for automobiles. Indiana is going to have a real racecourse.

Third Annual Successful Banquet of the Aero Club of America, Held at Hotel St. Regis, New York City, Saturday Night, March 20.

FROM auloing lo aeronautics is but a step, and the fact was acccntuated again at the lhird annual banquet of the Aero Club of America, held on lhe evening of March 20 at the Hotel St. Regis, in New York City. With Cortlandt Field Bishop at the toastmaster's place, and other such well-known autoists as Jefferson de Mont Thompson, Robert Lee Morrell, Peter Cooper Hewitt, Colonel John Jacob Astor, William McAdoo. Robert Graves, Charles J. Glidden, Alan R. Hawley, Dave H. Morris, Alfred Reeves, Augustus Post, Henry Sanderson, Dr. S. S. Wheeler, Waldron Williams, Dr. C. T. Adams, and a host of others in evidence, the occasion might have been transformed into an automobile function without the least embarassment lo the majority of those present.

Of course, the diners included a goodly number who possess distinctive aeronautical reputations, the prominent ones embracing Glenn H. Curtiss, of *June Bug* fame; Captain T. S. Baldwin, of dirigible airship excellence; A. M. Herring, whose new aeroplane is soon to havc a government trial; Charles Levee, hero of many ascensions; Charles Walsh, who has gone aloft frequently, and Albert Triaca, who teaches aerial flight.

Captain Homer W. Hedge, who figured first as one of the active spirits in the formation of the Automobile Club of America and later did similar effective work in the organizing of the Aero Club of America, sat at the same table with Philip T. Dodge, president of the Engineers' Club, who took a keen interest in those spceches dealing with aerial advance.

An intcresting exhibit at the dinner was the two large gold medals which the club will present to the Wright brothers upon their return to this country. The obverse sides show portraits of the brothers with an inscription giving their records:

"Orville Wright, Fort Meyer, 1 h. 14 min. 25 sec., Sept. 12, 1909."
"Wilbur Wright, Le Mans, 2 h. 18 min. 33 3-5 sec., Dec. 31, 1908."

The reverse sides show an exact miniature of the Wright aeroplane. These medals were designed by Victor D. Brenner and cost $2,000, being shown for the first time at the dinner. Rcplicas in silver and bronze have been struck and will be distributed among those who contributed to the medal fund.

Out in the lobby there was displayed a model of the Wright aeroplane. Over the guests' table hung a model of Baldwin's dirigible, while on the table itself reposed the *Scientific American* trophy which the *June Bug* won. The Lahm trophy also adorned the scene, and members were urged to go after it.

Among other things, President Bishop entertainingly said:

"When we started with the first banquet of this club three years ago it was a grave question whether we would be able to make the banquet an annual event. It looked as though we would have to wait several years for interest in aeronautics to grow in this country. but the attendance here to-night would seem to indicate that pretty nearly everybody now is interested, and in a serious way. A year ago I stood in this same place and made some predictions. I am happy to say that most of them have come true, and I may go a step further and say that developments have even outrun my prophecies. To-night I make the prediction that most of us here will live to see the Aero Club of America the strongest sporting club in the country."

Robert D. Davis, editor of *Munsey's Magazine*, supplied the humor of the evening. When Mr. Davis said that there was one thing about a flying machine that he was sure he should likc, it brought forth spontaneous laughter. "When you get up in the air," said he, "and something breaks, nobody is going to come around and tell you how to fix it." Martin W. Littleton contributed the rhetorical fireworks, and James W. Osborne also indulged in the higher flights of oratory. Colonel Henry W. Sackett, of the Fulton-Hudson Celebration Commission, told of the preparations for that event, which will include a $10,000 aeronautical plum; and John E. Parsons described the air journey of Wilbur Wright in France which brought to the famous American the kingship of the heavens and some $50,000. Then camc the moving picture entertainment.

SAFETY AND UTILITY OF AUTOMOBILE STEERING SYSTEMS

By Thos. J. Fay

Part III

MECHANICALLY, there are many things to take into account before it can be said that the steering equipment of an automobile will be up to a fitting standard, and it will interest the designer, the constructor, and the ultimate owner of the car, to go over steering details at some length, reviewing the several features, hoping thereby to gain an advantage. It has been shown how cars should be handled on the road, but the mechanical details are still unexplored.

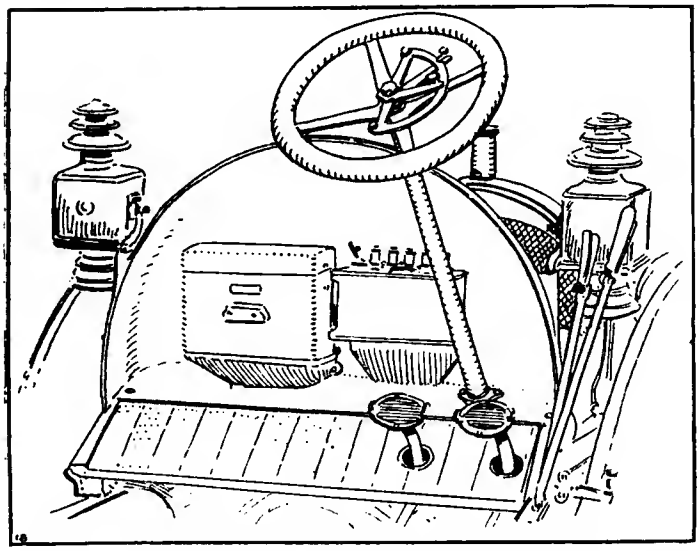

Fig. 18.—Characteristic steering wheel showing spark and throttle.

Familiar as the steering wheel is, even so, for the sake of completeness, it will be necessary to use illustrations, if clearness is to be a property of the text. Fig. 18 illustrates a typical steering wheel on its post showing the relation of the foot pedals, besides the spark and throttle levers mounted on the wheel. The wood rim of the wheel is oval instead of round, in order that the grip will be improved, and the hands will not fatigue so quickly as when the section of the wooden rim is round. The tilt of the wheel is usually such that the relation of the wheel to the driver's seat is as shown in Fig. 19, in which the distance from the seat to the rim is 9 inches.

The radius O B is usually about 28 inches, and, if the seat is less than 18 inches from the deck, which is the value allowed in the figure, the seat must move back so that the edge (front) of the seat will be bisected by the arc of the circle A C, in order that the radius O B will never be less than 28 inches, which seems to be the minimum allowable foot room. The tilt of the wheel will have to do with the strength of the column, provided the wheel is in the vertical plane, as shown in Fig. 20, for trucks, and the strains will be in the nature of bending moments. If the wheel is not strong and well braced it is likely to cause trouble, since the pressure will cause the same to bend. In the same figure it is shown that the tilt of the wheel, as it is designated for roadsters, affords the greatest advantage, since the work comes on as in a column. Likewise the figure shows the tilt of wheel columns for touring cars in which the moments are partially in bending, and the balance as in a column.

Lateral Location of the Steering Wheel.—Equestrians, when they mount a horse, with a view to experiencing a long, hard ride, sit up straight, and avoid all tendencies such as will cause curvature of the vertebra. In automobile work, owing to the overhang of the seats, it is not uncommon to observe that the steering wheel is not in the center of the driver's seat. The result is as might be expected; the driver is much fatigued in the course of a long ride, due to the ungainly position which he is compelled to assume, and Fig. 21 shows the approximate dimensions of the driver's seat as it obtains in some of the well-designed cars, in which it will be observed that the steering wheel is in the center of the seat.

In some of the earlier designs of automobiles it was the practice to employ what is known as tilting wheels, placed for the purpose of enabling the driver to more readily leave the seat. This plan looked like a good theory, and for a time it was regarded as a regular thing in automobile work. In the long run, the best results were due to a rigid steering wheel, and it was also found that the anchorage of the steering column could not be too good. Fig. 22 illustrates the manner in which the steering post is passed through the footboard, and when the proper angle is ascertained the separate plate, which is sometimes in the shape of a flange, is bolted down to the footboard. It may seem unnecessary to go into details of placing of the steering column to this extent, but autoists are in a position to tell of the large number of cases extant, in which the steering posts were not securely fastened. There is nothing which will disturb the nerves of an autoist so much as a steering column that is not securely anchored, and, if the fastening at the footboard is insecure, the lower fastening at the chassis frame will ill serve the purpose.

The Vertical Steering Post in Truck Work.—If the steering column is vertical, as shown in Fig. 23, care must be exercised to have the tubing of good diameter substantially flanged at the deck, and it will be quite an advantage to have a brace, or tie, further up. In this case the motor is under the deck, which form of construction permits the builder of the truck to offer a larger platform for goods, without the excess overhang at the rear, which is so prone to influence the tire bill, for the reason that the rear wheels have to sustain under more than a fair share of the burden.

Having thus indicated the extent to which lost motion is undesirable, as this lost motion relates to a flimsy fastening of the steering column, it may be well to go on with the discussion of lost motion as it relates to the mechanism for steering.

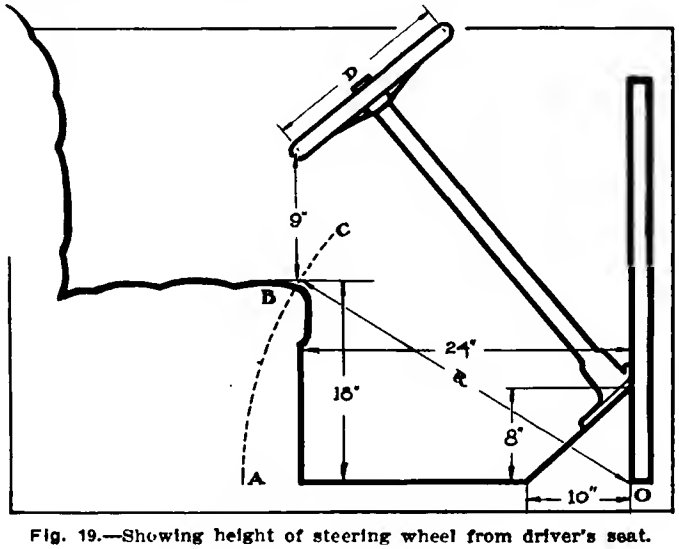

Fig. 19.—Showing height of steering wheel from driver's seat.

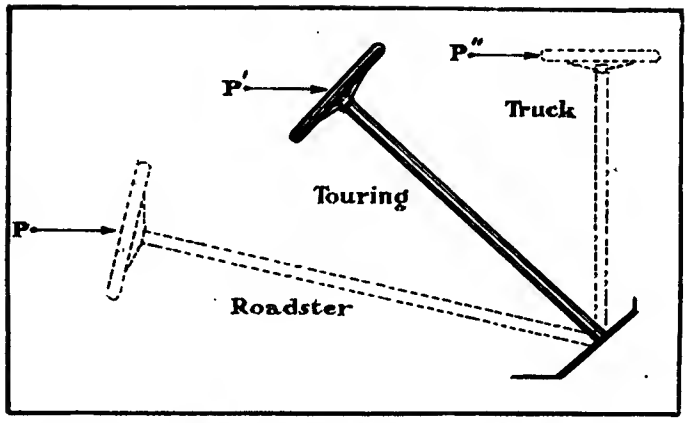

Fig. 20.—Indicating the advantages of tilt of steering columns.

Lost Motion in the Steering Mechanism.—There are three sources of lost motion in the mechanism as follows, *i. e.*:

(a) In the reducing gearset of the steering post, due in some cases to inferior designing, and again if the gear is absolutely irreversible.

(b) In the buffer spring placed in the dragrod for the express purpose of minimizing shock, hence requiring lost motion.

(c) In the joints and bearings through the system.

Some lost motion must be tolerated, since it is even desirable, and in its absence the parts will be subject to shock components that will engender fatigue in the metal, which in turn will be rendered manifest by crystalline (structural) formations in the body of the same. As an illustration of this crystalline growth, it is fair to call attention to the practice of annealing crane-chains at least once a year, for the express purpose of correcting the structure, rendered crystalline in regular service by the series of little shocks due to the chain rolling over the drum, under strain, which shocks are intensified by the unevenness of the links which bump against the periphery of the drum. It is the series of little shocks that have to be feared, as they abound in the steering system, in the cases in which no provision is made to dampen them. A spring, placed in the dragrod, in the manner shown in Fig. 24-a, will afford the dampening effect, but it is at the expense of some lost motion.

In order to have the dampening effect of the spring without excess lost motion it is necessary to include considerable stiffness and few turns. It is not desirable to have the steering interfered with, as it will be if a spring of many turns is used, and if the section of the spring is such that but little pressure will be required to compress the same. The spring shown in the section, Fig. 24-a, is made from square wire of a fine grade of spring steel, and, with four turns of the wire, the amount of play is reduced to very little, even under the most severe conditions of pressure. Even so, it is due to this stout spring that the metal in the steering parts will sustain in service, and a crystalline structure will be avoided.

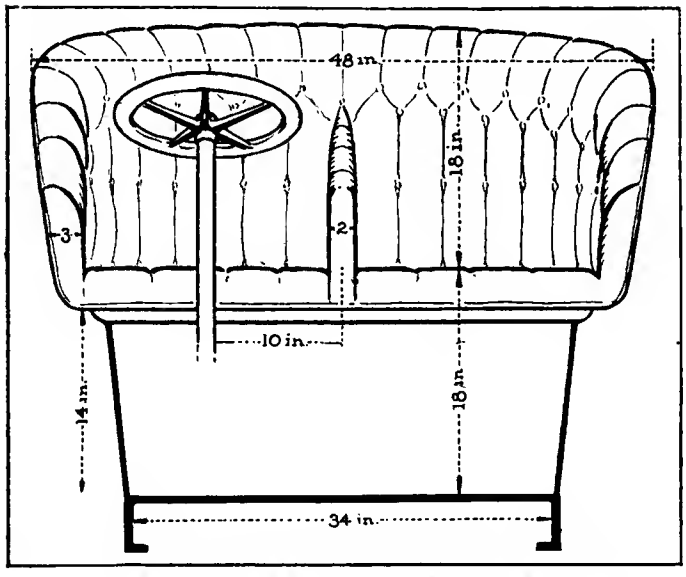

Fig. 21.—Illustrating the right lateral position of steering column.

Incidentally, and while the matter is on the tapis, it will be well to point out the manner in which brazing is avoided, in the process of assembling the dragrod, which details are also applicable to the tierod. Fig. 24-b shows the exterior appearance of the structure, and, as will be observed, the tube is threaded to receive the socket forgings, which does not prevent reinforcing the tubing at the ends, near the socket forgings, if the tubing used is thin. This operation can be avoided if the tubing is made thick enough to afford an adequate wall, despite the thread.

In automobile work it has been well demonstrated that nuts and studs will back off even if the thread is fine, and despite the use of tapers, or if the thread is a tight fit. Nuts have to be locked on, and in the case of the drag and tierods, in the steering system, it is necessary, nay, imperative, to relieve the situation of all risk, which can only be done if the locking question is extended almost to the extreme. Fig 24-a shows the manner in which the socket forgings are split, and how a clamping bolt takes care of the locking, which clamping bolt is, in turn, prevented from drifting off since castellated nuts are used, in which cotter-pins are placed to keep the nuts from backing off.

In this case the buffer spring is provided with a means of reducing the lost motion. If the spring is found to be too weak, adjustment is by means of a stud, with a locknut in the end of the socket forging, as depicted in Fig. 24. The socket faces are hardened, and the ball is also treated to render it hard. In this way the wear on the ball and sockets falls off to a minimum, and adjustment comes only at long intervals. Fig. 25 indicates the need of a fairly heavy section in crankarms (level-arms), and, since the ball generally comes at right angles to the axis, it will be well to take up the detail involving the hardening process.

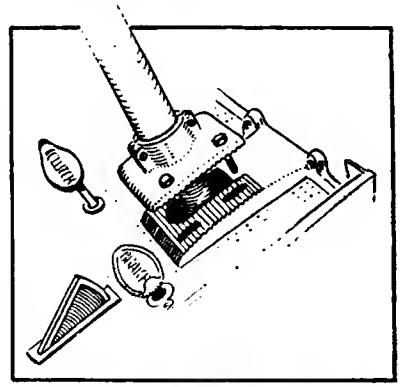

Fig. 22—Bolting flange for column at footboard.

Quick Methods of Hardening Fail in Service.—Heating a part to a red heat (or any other heat), and applying cyanide of potassium, will not grow a depth of carbon sufficient to be of any avail, on the ground that the time required for the penetration of carbon is greater than that which will obtain in the process as here suggested. Fig. 26 shows the rate of penetration of carbon in steel if the heat of cementation is 850 degrees centigrade, on the one hand, and 1,000 degrees centigrade on the other. If a piece of cementing steel is raised to 850 degrees centigrade, and if the same is packed in cementing material, the curve shows that it will take slightly more than 4 hours to grow a depth of carbon of 0.030 inch. If the same steel is heated to 1,000 degrees centigrade, the depth of carbon will increase to slightly over 0.050 inch, but if the heat is applied for a few moments, as it is in the cyaniding process, sometimes adopted in shops, it is assured that the depth of carbon will be but slight, say, 0.005 inch. This depth of the carbon, in density sufficient to assure that the surface will quench to hardness, is not enough to be of any service. In the meantime, taking into account the importance of the parts, such as the steering crank, which, it will be remembered, has to sustain under severe conditions, and considering the neck, under the ball, of small section, it is extremely dangerous to cement the same at high temperatures, and 900 degrees centigrade is probably the safe limit, allowing that the steel will be of a suitable grade. Owners of cars will find it to their ad-

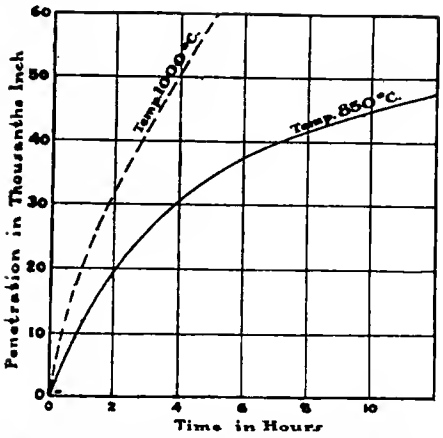

Fig. 26.—Curve showing penetration of carbon in cementing steel, in given time.

vantage to look into this phase of the question before they allow any repairs to be made, if the repairs have to include heat treatment of the steering crank or like parts.

If the ball and sockets are not hardened in a suitable manner, it will be but a short time before the ball will wear down to an elliptic shape, and lost motion will be present in consequence. All along the line this question will crop out, and it is the accumulation of little increments of lost motion that, added up, renders steering so disagreeable, if not unsafe, that autoing becomes quite out of the question. If lost motion follows in the cases involving inferior hardening of the bearing surfaces, securing the cranks to their respective shafts will lead to additional trouble of the most disagreeable sort if the work is not well done. Figs. 27-a and 27-b show one way in which the cranks are secured to the shafts with a view to eliminating trouble. In this case the crank is fitted in a taper, and the clamping bolt cuts through the shaft in the manner shown at *a* and *a'* to prevent the crank from floating off of the shaft, even if the nut *b* should come off. The nut is used to pull the crank up on the taper, and the key *c* is for the purpose of preventing the shaft from rotating in the hub of the crank.

A second method is sometimes used, in which the clamping

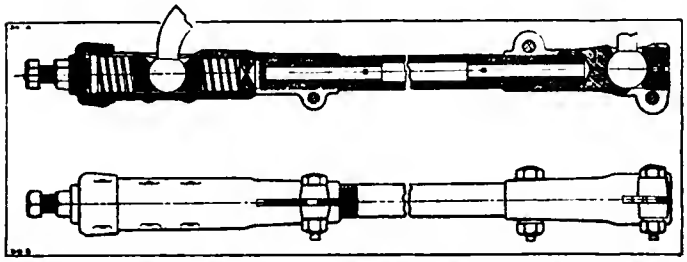

Fig. 24.—Section and plan of drag-rod, and manner of placing bumper spring.

bolt, shown in Fig. 27, is excluded, and Fig. 28 illustrates the point. In this case it will be observed that the crank is drawn up on a taper, and is prevented from drifting off by the nut used to draw the hub up on the shaft. The square shaft, as shown in Fig. 29, is much used, and if the work is well executed the scheme has the merit of serving well for the purpose. In this case the clamping bolt keeps the crank from floating off of the shaft, and if the bolt is drawn up tight there is small danger of lost motion.

It must be remembered that the clamping bolt is required to sustain under quite severe pressure, and that it will elongate a little at first is generally true. Under the circumstances it is necessary to take up on the bolt after a car has seen a little service, and it will be the height of folly to apply a long-armed monkey-wrench to the nut and pull until the bolt is partially twisted off, for, in all truth, it will come off of its own accord the very next day, and it cannot be said that the incident will transpire under the most favorable conditions.

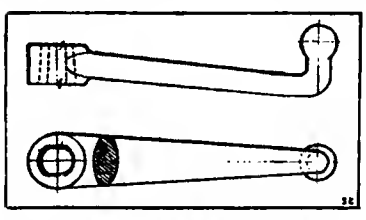

Fig. 25.—Steering wheel crank of usual form, with curved neck.

Care and Maintenance of the System.—It is unfortunate that all the

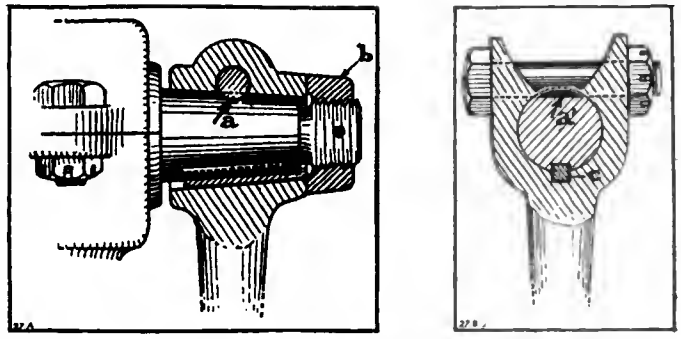

Fig. 27.—Longitudinal and cross-section of steering crank.

joints in the steering system have to be exposeed to the dust of the road, and to such mud accumulations as are bound to splash up, and on the parts when the going is bad. But this is all the more reason why the system should receive every possible care, and if leather protectors are not used, as they should be, it is necessary to clean out the joints at frequent intervals, apply hard grease to the surfaces, and pack the same into the cavities, on the theory that when the grease is in, the dirt is out. If the links and levers are so placed that they will be high off of the ground, in the manner as shown in Fig. 30, the amount of attention required will be a minimum, and the parts will be protected from damage due to a road obstruction to the maximum degree. In town work this is not so important, and as a rule the systems are so nicely devised that little is left to discuss. In touring work on unimproved roadways, however, it is with a fine sense of feeling that the location of the parts for steering are discovered up, out of harm's way.

There is still one unexplored field in which lost motion can become a serious factor, and in which repairs are serious to contemplate. This lies in the gearset in the steering system, the prime function of which is to enable the driver to steer the car, on a basis of safety, taking into account the angle of cant of the road wheels for a given rotation of the steering wheel. In most cars it is the practice to rotate the steering wheel 1½ revolutions in order to cant the road wheels the whole (combined) angle, and, considering some of the smaller cars, it is not uncommon to find that the combined angle of cant of the road wheels will follow one revolution of the wheel. Lost motion adds to the revolution of the steering wheel and introduces a lag in the response of the same, which becomes dangerous, if the amount is overmuch.

If the steering gear is absolutely irreversible, it is because the worm and sector in the gearset is cut to such a low angle as to

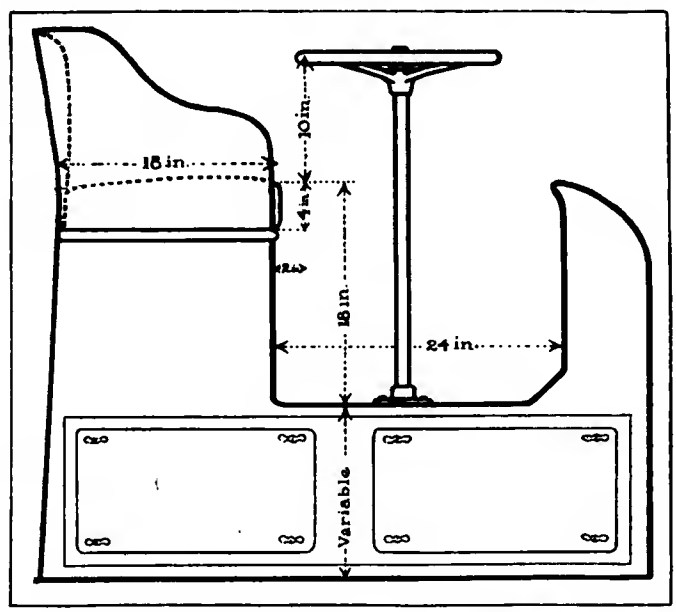

Fig. 23.—Vertical steering column used on certain classes of trucks.

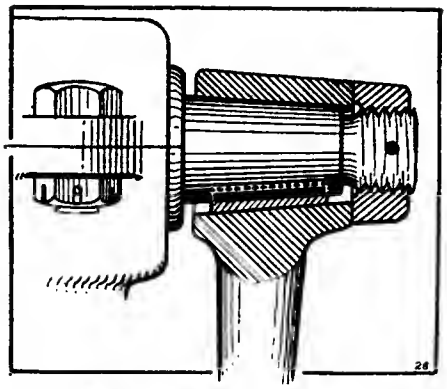

Fig. 28.—Common form of fastening of steering crank to the shaft.

render the same capable of responding in one way only. If the angle of the thread is about 10 degrees, the gear will hold to the irreversible principle, and since it is true that the movement of the wheel will then be a maximum, considering the resultant cant of the road wheels, it follows that lost motion will be the more noticeable. The best practice is in favor of such an angle as will make the gearset nearly irreversible, which angle is about 12 degrees, referring, of course, to the worm and sector types of gearsets.

In the screw and nut types there is the same condition to be met, but it is disposed of in quite a different manner, as will be shown at the proper time. If the system is absolutely irreversible great strains will be put on the members when the road wheels strike an obstruction such as will produce a reaction in the gearset. The very fact that a system is irreversible is proof of the blow which can be struck, and the damage may result, since, if there is a limit to the "give," there is almost no limit to the effect of the blow.

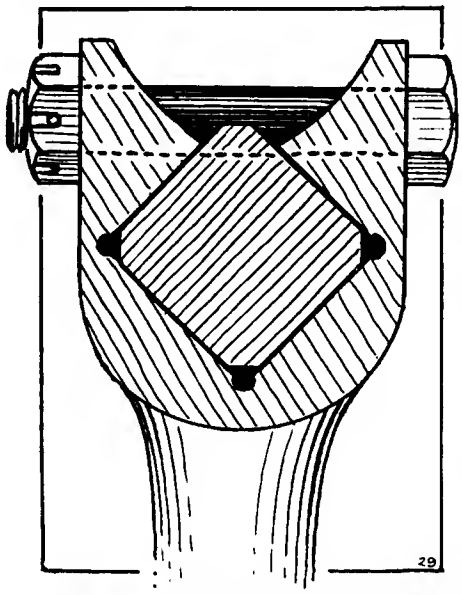

Fig. 29.—Conventional form of square shaft, illustrating means of clamping crank securely.

If the system is not absolutely irreversible, then, when a blow is struck, utilizing the road wheels to transmit the energy of the same, the lack of rigidity will soften the effect of the blow, and the system will thrive without the presence of any factor such as would react against the same. Absolute irreversibility then is not wanted, and a little lost motion is better than none at all.

(To be continued.)

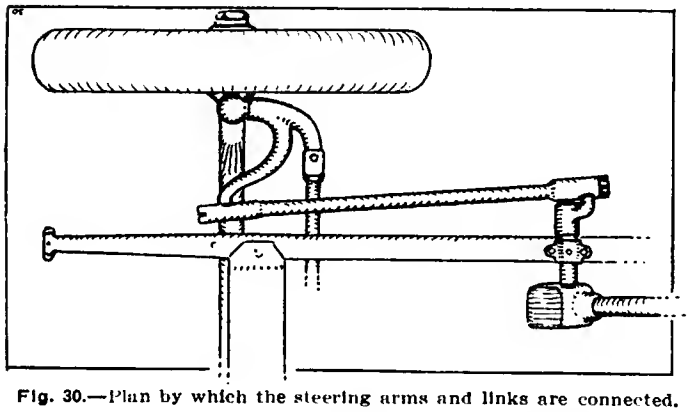

Fig. 30.—Plan by which the steering arms and links are connected.

ALUMINUM SOLDERING EXTREMELY DIFFICULT.

FREQUENTLY the question is asked, What is a good solder with which to solder aluminum? Generally the answer is, There is no good solder for the purpose. The "inhabitant in the woodpile" belongs to the genera which will respond to treatment in relation to which soldering is but a detail. Aluminum cannot be soldered in the ordinary way, and the failures which are made in the attempt are due to lack of appreciation of the difficulties encountered.

The general properties of aluminum are as follows:

Specific gravity	2.6 to 3.00
Atomic weight (pure)	27.1
Melting point (pure)	1160° F.

The aluminum alloys with which the automobilist has to deal hold about 90 per cent. aluminum and the balance is copper, manganese, zinc, and a trace of iron. The proportions of the alloying elements differ in the respective specimens, and as a result the characteristics reflect the differences. On the whole, however, the soldering problem, so called, will be very much the same, because the aluminum is in so much presence that it is the characteristics of this strange metal that will have to be coped with.

Primarily, aluminum on account of its low melting point, will not stand prolonged heating, as the case with copper, which is perfectly amenable to the soldering process. Then, aluminum suddenly "wilts" under the heat application, hence it requires careful treatment or it will be placed beyond the pale of soldering if it is to return to its original shape.

Fluxing and tinning is the process which renders soldering easy under ordinary conditions, and it is because aluminum will not mind this process that half of the trouble is experienced. It is fortunately a fact that zinc has a slight tendency to flow, and if the surfaces are clean and dry the chances of being able to make a fairly satisfactory repair will be eminent, provided the solder used is with zinc in pronounced quantity, alloyed with tin, and since aluminum is capable of entering into the solder it will be possible to use a slight amount of the same with a view to aiding in the process.

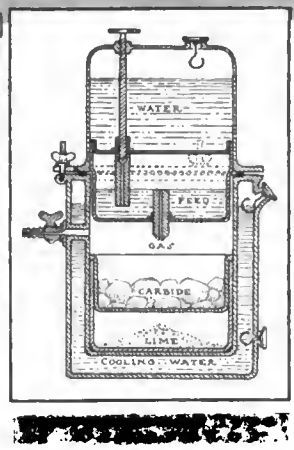
But since it is quite out of the question to keep aluminum surfaces clean enough to sustain a "tinning" process, even for a short period of time, it is plain to be seen that the addition of aluminum to the solder in any considerable quantity will tend to the very trouble which makes the operation so very difficult. The solder, then, must hold but a trace of aluminum. Even with solder of the character as above outlined, it will still be difficult to accomplish the task in the absence of due preparation of the parts to be soldered.

Since dampness is the bane of the process, assuming the surfaces are properly prepared, the safe method of proceeding will include the drying of all the surfaces, as well as the solder; this can be done in an oven at a temperature almost high enough to melt the solder. When the parts are dry and held at the drying heat, the next thing to do is to scratch the surfaces so vigorously with a metal brush as to bring out the real untarnished virgin metal, thus removing all traces of oxide.

The next process will include heating the metal to a point above the melting point of the solder, and after applying the solder to the surfaces actually brush it into intimate relation with the metal brush. If the solder refuses to adhere to the aluminum surfaces it is because the oxide is still present in sufficient quantity to defeat the aim. When the surfaces to be joined are well coated with the solder it will be a simple process to join them under the heat, high enough to melt the solder, and from that point on all the rules of ordinary soldering work will apply.

What is wanted for the purpose of heating is a good bunsen burner, although it is possible to do a fairly good-sized job with a good blow-torch; soldering irons are valueless for the work. Finally, it is necessary to perform the operations with dispatch. The surfaces must not only be cleaned as stated, but they must be free from aluminum oxide as well.

Economy Results From Understanding Acetylene



EFFECTIVE lighting is quite as necessary as a good automobile if one desires to travel under pleasurable conditions and if safety is to be present on the journey. Without attempting to compare the respective methods of lighting in vogue, it will be the aim to discuss the phases of lighting by means of acetylene, with particular reference to the calcium carbide used in the process. The first cost of the material is something to consider, but it is unfortunately true that the lighting will fail if the use of carbide is not attended with proper conditions.

Acetylene is produced by dissolving calcium carbide in water just as salt is dissolved, excepting that the carbide does more than salt, in that it combines with the water in such a way as to produce acetylene gas, the chemical formula of which is C_2H_2, and the residuum of which is slaked lime, for the most part. True, "commercial" calcium carbide is not chemically pure, and it is for this reason that the residuum is not pure slaked lime, barring the chance of introducing impurities, such as may reside in the water that is put into the generator for the purpose of making the gas.

That all carbide is even up to a commercial standard of purity is scarcely to be believed, nor is it desirable to try to use the cheaper grades of carbide, since they are not nearly so good for the purpose, and there is the danger of clogging up the burners as well as the piping and such other constricted passageways as will be found in the average lighting system in automobile work. Then, there is the question of the deterioration of the generator to be considered if the carbide is not pure, since corrosion may follow the use of the inferior grades.

Heat Is Generated When the Gas Is Formed.—A crude diagram of the generator is that depicted in Fig. 1, which has the advantage of simplicity and saves complication, thus rendering explanation free of extraneous detail. As will be observed in the figure, the carbide is placed in the chamber *C* and water is put in the chamber *A*. The water is free to drip through the passageway *E* into the middle chamber *B*. When the water fills the middle chamber up to the top of the pipe *F* it will pass down through the same to the carbide in the chamber *C*. When the water contacts with the carbide, gas will form, and when the pressure of the gas equals the water pressure, due to the head of water, the water will cease to flow because a condition of balance will then obtain. Upon opening the cock *D* the gas will be free to flow to the burner *G*. If the gas as it flows out of the burner, due to the pressure from the water "head," is contacted with a flame, as a lighted match, the gas will burn. In the meantime the pressure in the chamber *B* will fall and more water will then flow through to the carbide and the gas supply will be maintained. The process will also be attended by the generation of heat in the carbide and steam will form sufficiently to cause considerable condensation in the piping system, which, together with such other formations as may abound in the piping, makes for trouble before the system is very long in service unless provision is made to guard against it.

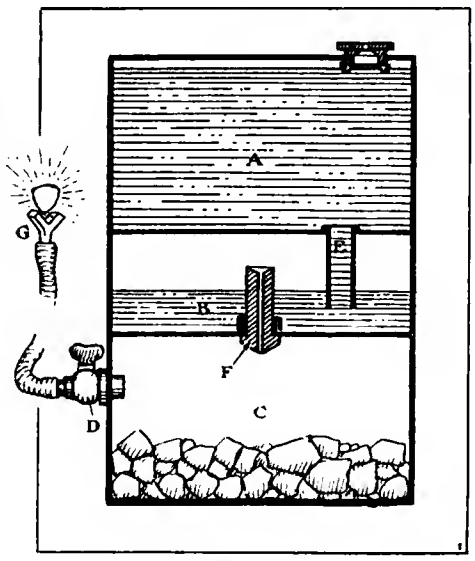


Fig. 1.—Characteristic illustration of automatic carbide generator.

Overheating is likely to be the source of considerable trouble, for the reason that, besides the impurities which will abound in the carbide under normal conditions, the excess heat will introduce activities that will result in soot, and products of a tarry nature will clog up the burners. The presence of this tarry residuum, coke, and, in fine, carbon in any form, will induce further additions of the same materials, since it seems to be the property of carbon under these conditions to augment the process.

The soot and tarry residuum which collect on the burner will adhere to the surfaces with a tenacity which will resist all attempts to dislodge the same, and the burners so incumbered will fail to perform further in a satisfactory way. The temperature at which this tarry residuum is formed is that which will form coke, as an outside figure, and the trouble begins at a temperature as low as 500 degrees Fahrenheit, which is easily reached in an ill-devised system of lighting.

Commercial Form of Calcium Carbide.—This base of acetylene is made in the electric furnace from raw materials consisting of lime and coke and the temperature of fusing is from 5,000 to 7,000 degrees Fahrenheit. The fused carbide is then crushed and the several sizes are selected out in a manner not unlike that which is used in the grading of coal. The grades are known as follows:

Lump, which consists of large sizes of carbide, ranging between 3 1-2 and 2 inches.

Egg, which is a medium-sized product, ranging between 2 and 1-2 inches.

Nut, such as will serve in carbide feed machines, ranging between 1 1-4 and 1-2 inches.

Quarter, which is the small pieces with dust removed, ranging between 1-2 and 1-4 inches.

Chemically pure carbide can be made in small quantities, but in the regular process, in which the carbide is made on a large scale, it is the "commercial" grades that are produced, and, as a rule, they are quite free from such impurities as will lead to excess trouble. The color of the "commercial" carbide is a dark brown, verging into the gray. There are grades of the carbide which are black with a red cast or strain. Carbide is hard and brittle, hence it lends itself to the process by which it is crushed and very little of the carbide goes to waste.

Calcium carbide is deliquescent, and to preserve its qualities it must be kept in tight packages so that water will not be absorbed by it, thus reducing its ability to form acetylene. It comes in tight drums in various sizes, and care should be exercised in its storage, since it will add flame to a fire if water is allowed to come into contact with it. As a matter of fact, the insurance regulations as they relate to this material are so very stringent that they preclude the right to keep even small quantities in insured structures without a permit.

Acetylene Burners Have Special Forms.—For burning coal or water gas the burners are of the "fan" shape, in

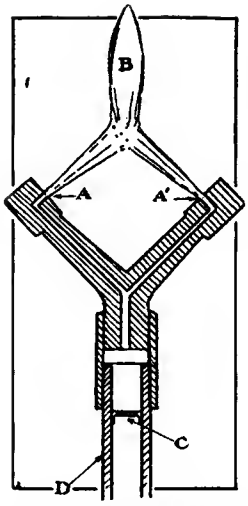

Fig. 2.—Section of acetylene generator.

which the orifice is in the form of a narrow aperture, and the amount of gas which will pass under the usual pressure, which is about that due to 4 inches of water, ranges from 3 to 5 cubic feet per hour. This is vastly more than is required in acetylene lighting, and besides the burners have to be so devised that too much heat will not be in evidence, and it is also desirable to arrange the aperture that the gas as it flows out will be well intermingled with atmospheric air to assure complete combustion and to abort the formation of soot.

The life of the burner depends upon how cool it keeps and upon the purity of the gas as it flows through the same. Fig 2 shows a characteristic form of acetylene burner in which *A* and *A'* are two small holes in the cheeks of the two prongs of the burners, producing the flame *B*, which rises above the burner, thus serving to bring the flame into the right relation to the mirror lens in the searchlight as well as keeping the burner as cool as possible. The screen *C* serves as a safety and to keep impurities out of the small holes in the burner. The tube *D* is a sleeve fit for the burner.

Acetylene requires about 12 1-2 parts of atmospheric air to one of acetylene for complete combustion, and it follows that every provision must be made to afford the requisite quantity of air if it is desired to prevent the burner from clogging and if the light is to be steady and bright, which is an absolutely essential incidental of the process from the economic point of view.

In actual practice it is not so much the candlepower of the light as it is a question of a short focus, and a symmetrical concentrated beam of light can only follow if the gas is burned in a burner of the right shape under the conditions in which the flame is steady and white. In order to be sure that the gas will be pure and in fettle to give the best result it is necessary to keep the pipes drained and clean. This is only possible if the piping is large enough to stand handling, and if it is so placed that it will drain to a low point, at which level a cock should be placed in order to be able to drain off the liquid accumulations.

The generator should be so designed as to afford an adequate supply at the right pressure, cool and free from soot, sand, tar and steam. This will be true if the generator is big enough for the work and if provision is made to scrub, cool and purify the gas as it is delivered into the piping system. In the meantime it is well to take into account that water in the generator, either to cool the same or for use in dissolving the carbide, will freeze in cold weather and care must be exercised to maintain the same below the freezing point unless calcium chloride is used in the system for the purpose of preventing freezing from taking place.

If calcium chloride is used for the purpose it must be chemically pure, and it should then be lined slightly to remove any acidity which may be in its composition. Fig. 3 is a curve of the freezing point of various compositions of calcium chloride in water, and, as a general rule, the less of the chloride used the better, all things considered. If the generator is water-jacketed it will be possible to use glycerine and water in this part of the same in the proportions of 3 parts water to 1 part glycerine, which will afford immunity, unless the weather is extremely severe. If zero weather is to be encountered it is only necessary to add more glycerine and a half-and-half mixture will be the limit. In so far as the water in the tank proper is concerned, the best plan is not to have it there until the lights are in actual demand, and it will be easy enough to add water out of the cooler system of the power plant, just when the lights are to be put into service. If the water is a little hot it will be well to allow it to cool off, although it will soon get hot in the carbide generator, as a result of the heating which accompanies the dissolving of the carbide.

Under no circumstances should the "sludge," which is the lime (residuum of the dissolved carbide), be allowed to stay in the generator after the lights are turned off finally for the day. It takes no longer to clean out the generator one time than another, and the generator will fall apart soon enough without hastening the process in this way. Such impurities as may reside in the carbide will do no harm until they are released by the water and allowed to float around in intimate contact with the surfaces of the generator. Electrolytic action is bound to take place, and in this process it takes but little time to reduce the generator to a state wherein it will make a better sieve than it will a generator. In contact with copper it has been found that a scale of an explosive nature forms, the character of which is not well established, although it is claimed that the formation is a carbide of copper. This formation is in small presence, and it has never been proven that it amounts to anything worthy of more than passing notice.

In conclusion, it will be proper to urge cleanliness and a full observance of the cautions which it has been the aim to spread out through this article, and if the generator is provided with valves, by means of which the water can be shut off, it will be well to keep them in good order, and use them for their intended purpose. Rubber piping serves very well indeed as the flexible connection for the piping, but it should be replaced when it is rendered *hors de combat*, and the joints should be kept tight lest the lighting will be poor, and it is also true that carbide costs enough to require that it be conserved.

The Piping Should Be Secured in Place.—In some of the cars, as they were put out in the past, it was the custom to allow the piping to go until the last, and in the hurried attempt to put it into place, after the completion of everything else, it was merely thrust into the chassis in a haphazard way, frequently without any attempt to fasten it into rigid relation, with the result that the joints would not stay tight. The pressure under which the gas is caused to flow to the lights is very little, and a small leak will suffice to put the lights out. With slipshod piping, and of small diameter, it is not to be expected that any good results will be experienced by the unfortunate owner of the car.

In view of the extreme importance of good lighting, and the utter impossibility of realizing the same if the piping is not fastened into place, it does look as if economies, if they must be practiced, should come from some other quarter. It would even be better for the purchaser to buy cars, less lamps, than to accept the lighting equipment if it is not installed in a proper and satisfactory way. Fortunately, the cars of the present day are in much better shape in this regard, and it only remains for owners to maintain the same.

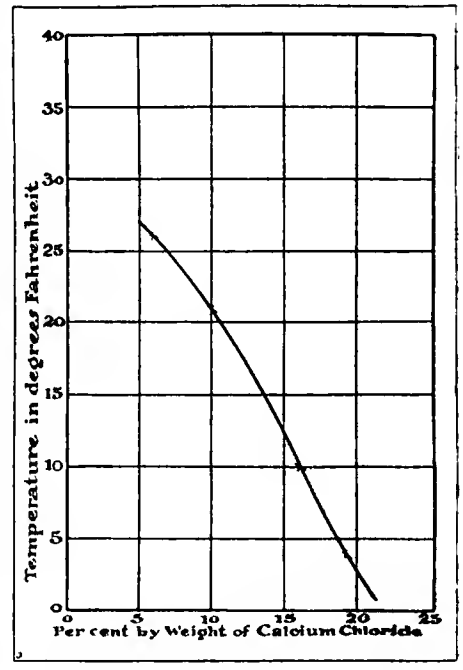

Fig. 3.—Chart of calcium carbide freezing temperatures.

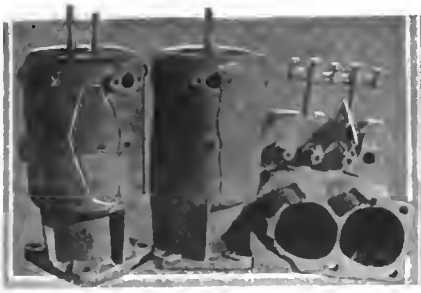


AUTOGENOUS WELDING EFFECTIVE IN REPAIR WORK

BY HENRY CAVE

AUTOGENOUS welding is proving a great boon to those who are unfortunate enough to have their cylinders broken, as they can be satisfactorily welded, and in the majority of cases, with a little trimming off, the repair will not show. In fact, some people require this, as they wish to sell their cars without the fact of the repair having been made being noticed. Cylinders with cracks are sometimes brazed, but, owing to it being necessary to heat the whole cylinder to a good red heat to even up the contraction strains, so as not to crack when cooling, the bore of the cylinder is generally warped, the job requiring a lot of finishing as the spelter and flux spreads considerably and is hard to remove. Also, owing to dirt and rust being deposited in the crack, it is difficult to get a braze below the surface. The heat used will sometimes crack the cylinder somewhere else.

Many Broken Water Jackets Traced to Freezing.—Cylinder breakage is due to carelessness or misfortune, probably in most cases the former, since, allowing the water in the jacket to freeze up, results in a fracture of the water-jacket wall. This cannot always be termed carelessness, as I have known an automobile to have all its water jackets cracked as early as the middle of October, when the owner had no thought of such a thing being possible. I have also known of cars being "hung up" on the road in cold weather, the driver opening the drain cocks before he left to summons help, upon his return found the water frozen with the usual results, this probably being due to too small drain cocks. Also, it is quite frequently the case that when shipping a car by rail in winter time the drain cocks will be opened, but due to some pocket in the water system (in some cases very small ones), which did not drain, the cylinders have become fit subjects for the autogeneous welder.

Curiously enough, the majority of cylinders cast from the same patterns will break in just the same place when frozen up. In a number of cases the break causes a piece of the wall of the water jacket to be entirely detached, and the breaks occur so near alike, in similar cylinders, that it would be possible to take the detached piece from one and weld it into another, even the smaller irregularities coinciding.

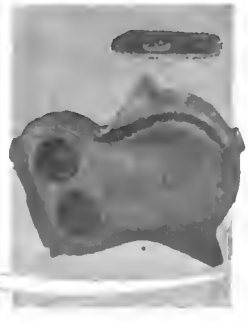
When a break of this nature is autogenously welded, by means of the oxy-acetylene flame, the crack or edge of the broken part is prepared so as to leave a groove nearly through the metal. The whole part is than heated to about 500 degrees, uniformly. This is not enough to warp the bore, as has been repeatedly proven by careful measurements before and after treatment. The sides of the groove are fused together and filled from a rod of cast-iron, the resulting weld being very neat in appearance, not generally requiring any finishing, and is as strong as the original wall.

Breakages Traced to Defective Designing.—The next class of breakages, in order of frequency of occurrence, are those in which the wall of the cylinder, combustion or valve chamber, is broken or cracked. These are in most cases due to freezing, but a certain number of them occur, due to the designer making a flat surface too large without adequate ribbing to support the intermittent pressure of the explosion.

Another case is the breakage of the connecting rod, allowing the piston to strike the top of the cylinder. Damage due to this cause occurs more frequently in two-cycle engines as the deflector on the piston readily punches a hole in the combustion chamber wall. This kind of break also often occurs, due to foreign substances, such as the head of a broken valve getting between the piston and the cylinder head. This class of breakages are the most difficult to repair, as it is necessary in most cases to cut a section of the water jacket to be able to work on the inner wall, the only deviation occurring when the break happens to be opposite a large hand hole. This operation could be well called "laparotomy," from an operation performed on the human body.

It can readily be seen that it is impossible to save cylinders when the break occurs between a pair, or behind the valve chamber, as it is impossible to reach these parts with this small flame. If the crack occurs in the bore it is necessary to be careful to weld only to within a sixteenth of an inch of the bore, or the finished surface will be spoiled, the crack left in this way being of small importance. Sufficient metal is built on the outside so that there is no doubt about the strength. After welding the break, the section of the water jacket which was removed is welded back in place.

Some Skill and Judgment Required in the Process.—As it is often impossible to determine the length or exact locality of the cracks before cutting away the jacket, and it is desirable to remove as small a section as possible, it is found necessary to cut additional pieces out, necessitating welding a number of small pieces back in place when finishing the job. This is sometimes impossible, and a sheet steel substitute must be hammered out and welded in place. The next series of breakages, in point of number, are those in which all, or a portion of the flange which holds the cylinder to the crankcase, is broken away, either due to there being insufficient metal to withstand the strain or to carelessness in assembling. These breakages occur in two ways: the wall of the cylinder may be broken away, or part of the flange may be cracked off. In the latter case it is an easy matter to make the repair, but when the break runs through into the bore of the cylinder, considerable care is required, it being first necessary to consider whether it is desirable to weld in the bore, which would then require machining, or, at any rate, filing out, as against a groove, and weld from the outside, to within a sixteenth of an inch of the face, sufficient metal being added to the outside to insure ample strength. This, of course, leaves the crack on the inside, which, however, can be smoothed down, and is not objectionable for a repair job, not interfering with the satisfactory operation of the motor in any way, providing a man of fair skill takes into account the Davis-Bourbonville system of autogenous welding, used by the Autogenous Welding Equipment Company, of which I am the president.



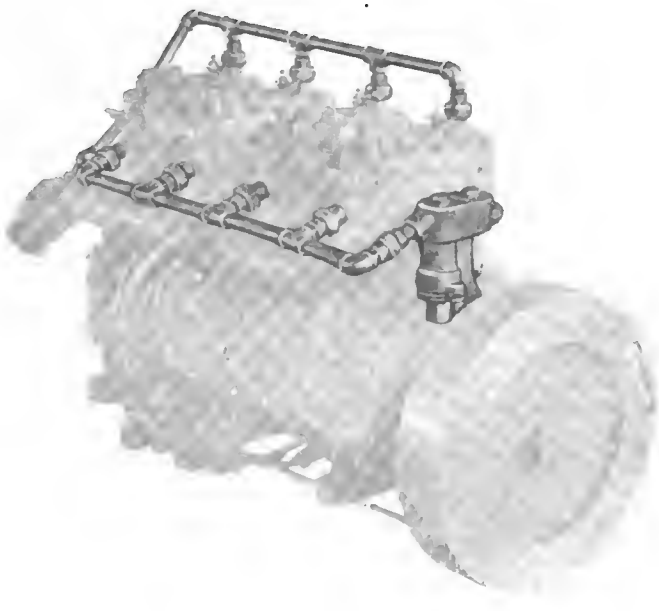
Automobile Cooling Systems Analyzed

BY MORRIS A. HALL PART II

THERE are two methods of fluid circulation, the so-called natural method and the forced process. Leaving the former for the present, the forced circulation of the fluid may be be accomplished by the use of a pump. These are, generally speaking, of two kinds, the rotating and the reciprocating. In the rotating class there are three further sub-divisions, the vane type, the centrifugal style and the gear pump. The other class is not so diversified in that there are no further divisions, the plunger type being the only reciprocating pump used.

Analysis of the Various Types—The Plunger.—Without going into the efficiency of the various classes, the plunger type is not popular because of the nature of its action, making it noisy. To get a large volume of water from this type it must be of a very large diameter, have a long stroke or run at an exceedingly high rate of speed. The first and second make a very large and consequently heavy outfit. The last will not have these faults, but in starting large bodies of water, always an immobile liquid, from rest to a high velocity in a short space of time, will consume a great deal of power. In use, however, the smaller sizes are very satisfactory for motor work, as the writer can testify. An additional point against this form is the inertia of the moving parts of the pump itself and entirely independent of the volume of liquid moved. This inertia is defined as that property of a body, by virtue of which it tends to continue in the state of rest or motion (in which it may be placed) until acted on by some external force. It is therefore a function of the motion and the velocity, and the greater either one of these the greater will be the inertia.

As the weight of the moving parts increases, this becomes greater; similarly, with increased velocity, this increases. Water being very incompressible, a strong and therefore heavy piston is used to work it, from which it is easily deducible that the inertia is great. The idea previously advanced of the necessity of speed to produce quantity, bears this out, from all of which it is plain that the internal losses in this type are very high. Fig. 1 shows a four-cylinder engine equipped with a plunger pump driven by an eccentric on the prolongation of the camshaft. In the next figure, No. 2, the detailed construction of this is shown, from which will be noticed the angled valve seats, eccentric drive and other prominent features.



The Plunger Pump Is Well Adapted to Marine Work.

Advantages and Disadvantages of the Rotating Type of Pump.—The rotating form of liquid circulation is in common use, and without accurate detailed figures it would be impossible to say which one of the three forms enjoys the most popularity. The vane probably would be assigned the last position. As used, this consists of an eccentric, rotating within a cylindrical chamber, to one side of which the water has access. This eccentric carries on its axis a pair of sliding vanes, which give the type its name. As the eccentric rotates and sweeps out the volume of the fluid chamber, the vanes, by sliding back and forth in the rotor, maintain the tightness and prevent leakage. The springs which keep the vanes tight against the case really act as a stuffing box to retain the fluid, and upon the spring-tension depends the amount of "slip" and friction. Considering that there is not only the hydraulic loss to consider, but also the high friction loss, it is not strange that this form is not increasing. On the other hand, it has many friends. Fig. 3 shows the component parts of a pump of this type.

The available figures for one of the recent shows indicate that 25 makers using rotating pumps were divided as follows: Gear type, 8; centrifugal type, 18. This hardly indicates the relative popularity, for those who did not give figures are mostly classified with the former division.

The Gear Type Is Marked by Simplicity.—Taking up the gear pump, it is found to be simple to care for, simple in principle and cheap to manufacture. The essentials of this type consist of a pair of gears, a pair of shafts for them to rotate on and a case to house the gears, act as bearings for the shafts and convey the water to and from the gears in a proper manner. The gears may be and usually are of the same size, but this is not a necessity. It is a necessity, however, that they mesh correctly, so as to rotate together without grinding or unnecessary friction. This is effected by correct cutting of the teeth and exact spacing of the shaft centers. The shafts are usually straight pieces of round stock, preferably bright stock which is commonly called cold-rolled steel. Gear cutting is done on an automatic machine and many, or at least several, gears are cut at once. The case is a simple casting, with very little machine work on it, from all of which it is easily seen that the statement above as to manufacturing cost of this style of pump was not far-fetched nor an exaggeration.

In this case the losses must be low for two reasons: First, the frictional loss due to the movement of the water or fluid used and, second, the nature of the pump itself with its form of motion. To enlarge on the first, the liquid, as may be seen in Fig. 4, is not started and stopped with consequent high internal friction and power losses, but is led in a continuous stream around several easy curves. These, of course, entail some frictional losses, but they are as nothing compared to the same quantities in the previous case. The form of the rotor is such that it does not slide over or, in fact, touch the sides of the

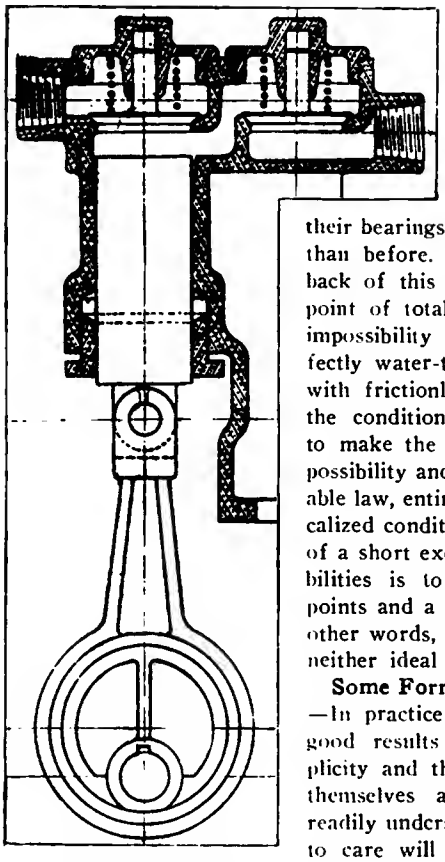


Fig. 2.—Plunger pump section

chamber within which it rotates. This at once eliminates the high friction losses due to that cause, and the efficiency of the shafts rotating in their bearings is but slightly greater than before. However, the drawback of this type from the standpoint of total efficiency lies in the impossibility of reconciling a perfectly water-tight rotating member with frictionless rotation. This is the condition which has operated to make the rotary engine an impossibility and is a fixed, unchangeable law, entirely independent of localized condition. The result, then, of a short excursion into the possibilities is to indicate some good points and a few shortcomings. In other words, this form is good, but neither ideal nor perfect.

Some Forms in Practical Work.—In practice the gear pump gives good results because of its simplicity and the fact that the parts themselves and their action are readily understood. A few hints as to care will not be out of place. First of all, like all rotating bodies, the shaft bearings must be lubricated to reduce friction to its lowest terms. This sounds simple, but is not, for the fact is that the flowing fluid has a tendency to wash away the lubricant. For this reason alone oil will not do. It is too easily carried away by the water. Another reason is that the heat in the fluid, particularly after a prolonged run, is great and will rob the oil of its lubricating qualities. A lack of lubricant, allowing the bearings to heat, will have the effect of burning up oil when it is put in.

Now, to overcome this a substance must be used for pumps which will not burn out and will be so immobile or unchangeable in its form that the water can not alter it nor wash it away. Such a substance is hard grease, but care must be exercised in selecting it for its lack of mobility, else the purpose of its use will be defeated. Fig. 5 shows a cross-section of one of these pumps and also indicates an excellent method of lubricating the same. The gears, in order to keep them light, are cored out. In assembling, this interior space is filled with a grease, of the quality just described, which flows out through the hollow shaft to the bearings. In this manner the pump is self-lubricating, and by putting in the proper grease at the start the manufacturer is sure of the desired results.

Centrifugal Type Has Many Good Features.—The centrifugal type is perhaps the easiest of all to understand. It consists of a rotating member, which may or may not be integral with the driving shaft, and a case, usually for manufacturing convenience divided into two parts, the case and the cover. In operation this is rotated at a high speed, and the water entering at the center flows out the arms, and at the extremities is thrown off by centrifugal force. This throwing-off action is restricted by the case, so that the effect is to throw the water into the outlet pipe, which is but another way of saying that the velocity has been increased over what it was at first. That is, the speed of fluid circulation has been increased by the pump. This speed is predetermined in the design, and varies with different designers, an average figure much used in practice being the same speed as the crankshaft. This is convenient to use and in gear-cutting also.

This force acts in a straight line tangent to the circle of rotation and can be very simply expressed. Thus:

$$(8)\quad F = \frac{W v^2}{g R}$$

in which

F = the centrifugal force.
W = the weight of the rotating body in pounds.
v = the linear velocity of the center of gravity of the body in feet per second.
g = the force of gravity = 32.16.
R = the radius in feet of the path of rotation.

Of these, g is known to be a constant; the radius of the path R cannot vary, nor can the weight of the rotating body at any instant. Now, the velocity of rotation may for convenience be expressed in terms of the number of revolutions, thus:

$$(9)\quad v = \frac{2 \pi R N}{60}$$

This introduced into equation (8) gives:

$$(10)\quad F = \frac{4 \pi^2 N^2 R W}{3600 g} = \frac{W R N^2}{2933}$$

By removing the constant quantities in this, it may be simplified to:

$$(11)\quad F = K N^2$$

This simple equation shows at a glance the advantage of the centrifugal type of pump and the condition necessary to obtain it. The centrifugal force F is the measure of the output, and this varies with the square of the number of revolutions. So, if a pump at 100 r.p.m. produces 2 gallons of water, the same at 400 will give 32 gallons, and at 800 the production will go up to a total of 128 gallons.

Fig. 6 shows the dissembled parts of a centrifugal pump and the outfit put together, ready for use. This gives an idea of the number and simplicity of the parts. In comparison with this is given Fig. 7, which shows a pump in position, with the water piping from it to the various cylinders and from these to the radiator, only a hose connection from the upper pipe to the top of the radiator and another from the bottom back to the pump

Fig. 3.—One form of vane pump, showing simplicity.

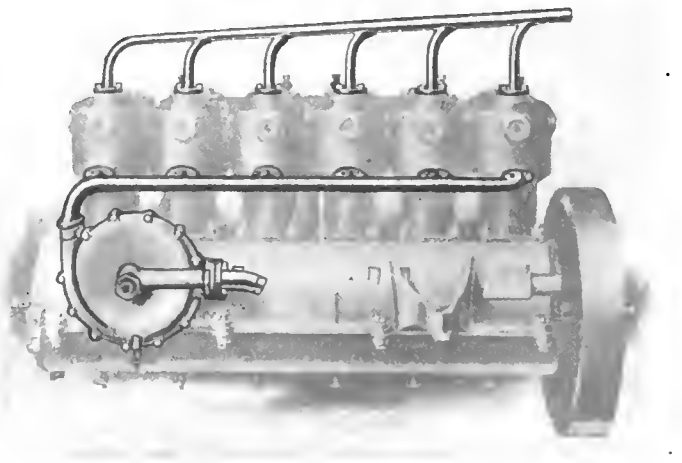

Fig. 7.—Centrifugal type applied to a "six."

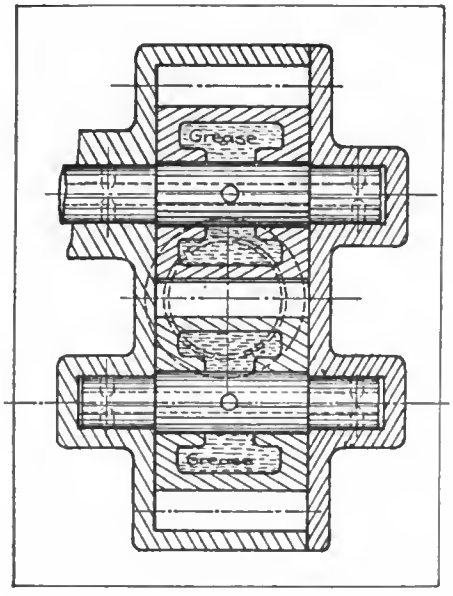

Fig. 5.—A simple lubrication method.

being necessary to complete the entire water circuit.

This figure also shows the variation in the size of pipes which accommodate more water as more flows in. On this point designers differ, but it seems reasonable that an increase in quantity should call for an increased cross-section. As the quantity should be equal in each cylinder, the amount flowing is multiplied by the number of cylinders. Thus, in the case of a "six," the area of the pipe at number six would be six times that at number one. That this does not mean as ugly a construction as one would think is shown by figures. Starting with a 7/16-inch diameter, six times this area is obtained in a 1-inch pipe.

Radiator Wipes Out Heat from Water.—Having covered briefly the subject of fluid circulation, and the means in common use for effecting it, it will be well to turn to the types and functions of the radiator. Going back to the subject of heat losses, a moment's thought shows that whatever heat is communicated to the water in the cylinder jacket, regardless of the means of moving this water around, must be wiped out by the radiator so that the water may be used over again. In a motor boat this necessity does not exist, for the same water is not used continuously, but flows away and is replaced by fresher and cooler water, the supply being unlimited. Now in the automobile engine the supply is not only limited, but, in addition, is reduced to its lowest terms. That is, as little water is used as will do the work and no more on account of its excessive weight.

In fact, the former practice of using a surge tank, to which the water flowed from the radiator and from which the pump drew its supply, has been entirely abandoned. One fact which was unknown at the time the tank was used, and which would have caused its abandonment ultimately, was brought out in the first part of this article, viz., that it is possible to have too much water and thus keep the engine too cool, which materially reduces the efficiency of the latter.

At any rate, whatever the amount of fluid used or the method of circulating it, the fact remains that the radiator must cool it down to the temperature it had previous to going to the jacket. This is what the opponents of the fluid-cooling method have for the basis of their argument that these are indirect methods. They are indirect, for the water first cools the cylinders and then air is used to cool the water.

Specific Heat of Air and Water Enter Into the Problem.—Here, that is in the indirect method of cooling, the specific heat of the substance used, enters. The specific heat is the measure of the heat required to raise a certain weight of the given substance 1 deg. as compared to the same ability of water, the latter being taken as the starting point or unity. This term is not relished by some as being inaccurate, so there is the alternative term, coefficient of thermal capacity.

As stated before, this figure for water is 1. For air at constant pressure, as in this case, the coefficient is .2375. Expressed otherwise, the ratio of the heat to raise air 1 deg. is to the

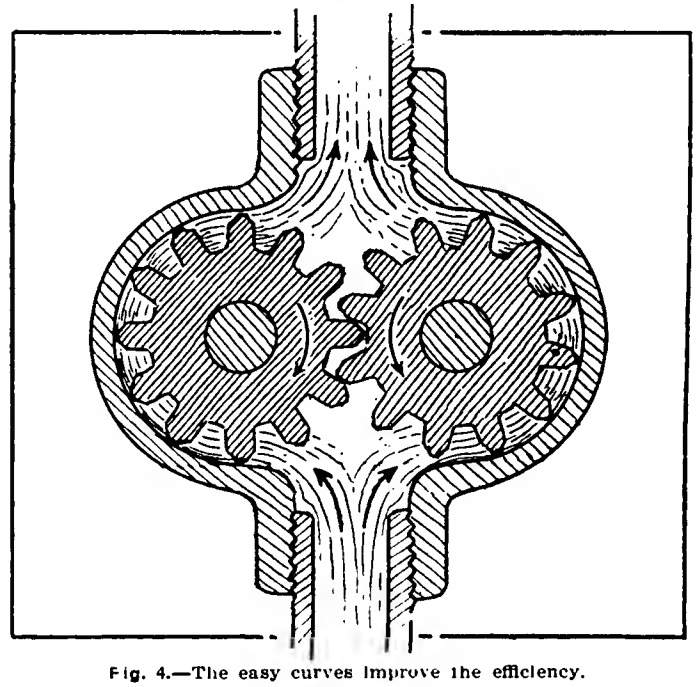

Fig. 4.—The easy curves improve the efficiency.

heat to raise water 1 deg. as .2375 is to 1. This renders it apparent at once that air has less cooling ability per unit of volume than does water, therefore to do the same work, or, more correctly, to remove an equal amount of heat, a greater volume of the air will be required in the inverse ratio of the specific heats. That is, the heat required to raise air 1 deg. is to the heat required to raise water as 23 is to 100. From this, the volume of air equivalent to the water in heat removing ability is to the latter as 100 is to 23.

$$(8)\quad \frac{\text{Thermal capacity of air}}{\text{Thermal capacity of water}} = \frac{.2375}{1.0000}$$

$$(9)\quad \frac{\text{Volume of air for equal heat-removing capacity}}{\text{Volume of water for equal heat-removing capacity}} = \frac{1.0000}{.2375}$$

(To be Continued.)

Letters Interesting and Instructive

WANTS GEAR RATIO FOR HILL CLIMBING.

Editor THE AUTOMOBILE:

[1,802.]—Will you kindly advise me through the columns of The Automobile on the following: I expect to install a 14-horsepower horizontal motor in a car, weight about 1,000 pounds empty, and would like to know the best gear ratio to have on jack shaft; also how many teeth the small sprocket should contain, and also the sprocket on rear wheel.

Will use sprocket and brake drum combined; sprocket will have either a 10½" or a 12½" hole. I presume one-inch pitch is usual?

Want to have a strong going car and a perfect hill climber; speed is secondary consideration.

Will you give me slow and fast speed on ratio you suggest?

New York City. W. COOPER.

If you adapt a lateral "jackshaft" on the chassis frame and a sidechain drive, which information you do not give, the bevel gearset can be with a ratio of 3 to 1, and the driving sprocket wheel can then be but little smaller than the driven sprockets on the rear wheels. It is of the greatest advantage to have the sprocket wheels of a good diameter, and the best results will be realized if the smallest sprocket has not less than 18 teeth.

In your case it is believed that the rear road wheels should run about 30 per cent. of the speed of the motor, which question is a little obscured by the failure on your part to state the diameter of the rear road wheels. At all events, it is possible that the best results would follow if the high speed is approximately 30 miles per hour, and if there are to be but two speeds ahead. It is then that the low speed should be about eight miles per hour. If the motor will deliver maximum power at about 1,200 revolutions per minute, and if the tires are 30 x 3½ inches, which will be the minimum size to use on the front and rear wheels of the car, the high speed, with a ratio of 3½ to 1, will afford a speed closely approximating 30 miles per hour.

If the car is to be equipped with a gearset with three speeds, which would be a good idea, the speeds might be graded in this manner: Low speed ahead, 8 miles; intermediate speed, 16 miles, and direct on high, at say, 32 miles per hour. If a planetary gearset is used, it is not believed that it will be possible to take any considerable advantage of the suggestions here offered, and the chances are that the driving sprocket will have to be used under conditions involving less teeth than the number stated. If it does become necessary to use a sprocket with a small number of teeth, it will be desirable to have the same cut with great accuracy, using a fine grade of steel for the purpose, and it would even be an advantage to put the sprocket through a suitable case-hardening process.

THE CORRECT NUMBER OF BATTERIES.

Editor THE AUTOMOBILE:

[1,803.]—In one of the recent issues of "The Automobile" there is an article on batteries being connected in series multiple, four in series. I have a six-volt coil. Should I use six in place of four? Do you think vaseline a good lubricant for ball bearings on front wheels? LOWELL S. ELLIS.

Warren, Mass.

The number of batteries is still a mooted question, and if you re-read the article in question you will see that the author did not decide upon the proper number to use in any given case, but simply selected four because of the economy. The average dry cell of small size will give 1 1-4 volts. Connected up in multiple, the voltage is multiplied by the number of cells. If you wish to get six volts, then you will use $\frac{6}{1\frac{1}{4}} = 4.8$, you may then use the next largest number, 5, or if you prefer, an even number, which is usual, 6.

Vaseline is a good lubricant, but a good grade of grease is usually considered better.

TO OBTAIN BEST IGNITION RESULTS.

Editor THE AUTOMOBILE:

[1,804.]—Please tell me through "Letters Interesting and Instructive" what to install to get the best ignition results from a four-cylinder motor; a single vibrating coil and distributer, or a four-unit vibrating coil and a timer, and why? The old coil throws the ignition out of time, as some of the vibrators don't seem to get busy until the rest are all done. When put in good order, it will not hold out for more than a hundred miles. Use a storage battery for current supply. A SUBSCRIBER.

New Richmond, Wis.

Either system has some disadvantages. The apparently simpler system, the first, has the disadvantage that the work of the coil is quadrupled, and the trembler must operate in the same ratio. For this reason, it is likely to get out of order or wear out much quicker. With the other method, it is difficult to get the four tremblers tuned just exactly alike. The result of this is to vary the spark and consequently the power, so the engine will run irregularly. A four-unit coil with a single trembler for all the units is preferred by some.

VERTICAL AND HORIZONTAL MOTORS COMPARED.

Editor THE AUTOMOBILE:

[1,805.]—Kindly advise through your paper as to whether a horizontal motor of four-cycle is stronger than the same in two-cycle? Also, if an 18-horsepower horizontal motor is simpler in construction than an 18-horsepower vertical? Which of the two, providing their make is A No. 1, is less foolproof; that is to say, which would give the less trouble in the general running; both have shaft drive and all things equal, as to magneto, etc.?

New York City. A. C. TONNING.

As to power, there is no difference between a horizontal and a vertical motor, the advantages being aside from this question. The advocates of the vertical type claim accessibility, while those who prefer the horizontal kind say that it takes up less space. Between the two and four-cycle motors, the power varies. Theoretically the two-cycle should give twice as much as the four-cycle of the same size, but in actual practice this decreases to about 1 1-3, owing to internal losses which up to date seem to be insuperable. The opponents of this type say that this advantage is partly offset by a lower fuel economy and the inability of this type of motor to run either very slow or very fast.

CONCERNING CREDIT DUE THE LANCIA "LAMPO."

Editor THE AUTOMOBILE:

[1,806.]—In your issue of January 21 last, on page 167, I have found, upon my return from abroad, an article which has placed our car, the Lancia, in a very unfair light, and has given your readers a false impression of the "Lampo" runabout, which won the Savannah Light Car race. I see no reason why there should be such a lack of sporting spirit in the American automobile fraternity. To be specific, this article informed your readers that the Lancia car was

> "a special one, built for racing, lightened even to the extreme of a frame drilled full of holes, fresh from tests and trials in England, and sent over here in perfect condition, in ample time to work over the course—this car in a distance of 196 miles, and a total elapsed time of 3 hours 43 minutes 33 seconds, gained a total of 6 minutes 12 seconds over its nearest competitor, an American stock chassis, and 10 minutes 22 seconds over its third competitor, also an American stock chassis. It is a matter of record how much delay from tire and other trouble was experienced during the race by the three cars."

I wish, therefore, to make this statement, which I am willing to back up satisfactorily, to make it worth while investigating by the writer of this article.

The Lancia car which won the Savannah race was not a special built car in any sense of the word. The bore and stroke of the motor are identical to a millimeter with the cars we sell out of stock; the bevel gears in the rear axle have the same number of teeth as our stock runabout chassis, and, with the exception of the drilling of the frame and the addition of a hand spark advance,

differed absolutely in no respect from our regular stock runabout as offered to the public. This chassis has never been on English soil; was never in any test or trial there, and, as a matter of fact, was not received in this country in perfect condition. It was sent to Savannah by Adams Express, and received there only three days previous to the running of the race, and had it not been that we had a very competent corps of mechanics at our disposal, I feel sure our car never could have won the race, owing to the hurried manner in which it was put together at Lancia's factory. At the time we cabled we would enter this event, there being no runabout chassis in stock, it was necessary for them to build one in a very limited time.

Our cabled order for this car was sent from New York October 15; that car was then assembled and tested by Lancia himself, not exceeding 20 miles; the car was then shipped on "La Savoie," arriving November 14, and then sent South by express. I think, under these circumstances, that the victory of this little car is extremely creditable, and would refer you to our issue of December 3, where, I think, justice was done and the secret of our victory was explained, namely, that we did not stop for a single mechanical adjustment or repair during the entire race—which was not true of our most disappointed competitors.

In further consideration of the statement to which I object so seriously, may I point out that the car that ran second, in this event, was of special build, in that the frame was undersiung; the cylinders were exactly up to the limit permitted by the rules, being one-quarter of an inch more diameter than our cylinders. It was also lightened up so that its weight was at least 300 pounds less than our entry. This car, with its team mates, and most of the other entrants, had been upon the ground at least a week in advance of our arrival, and were consistently practicing every day.

What difference, may I ask the writer, does it make which of the first three cars had the greatest power? The race was run at a pace that killed, as shown by the condition of some other cars which finished the race. The writer further informs the public that the third car did not win the race, being handicapped because it had to reduce its bore. Did not the entrants in this race know that the event was intended for cars of 3 3-4-inch cylinders; and if, knowing this and that their cars would be seriously handicapped, why did they enter the contest?

I sincerely hope that we have another such event next year, and, knowing the rules beforehand, if it is not advisable to enter cars because of changes which have to be made, let us abstain from racing, and not make the changes the basis for our excuses for not winning. Or, if our cars do not win because of defective material, or their inability to negotiate the roads set apart for the race, because of the design or construction of the cars, do not let us blame the tire manufacturer or belie the winner in an effort to distract the attention of the public from our faults. Under such conditions and keen for clean competition, I shall be glad to enter a Lancia car in any event in which I believe it has a chance to win, or will at least show the public that it has the kind of stuff their dollars ought to buy. C. H. TANGEMAN.

New York City.

LANCIA LAMPO'S USE OF PANHARD OIL.

Editor THE AUTOMOBILE:

[1,807.]—An unusual situation has arisen in connection with the Light Car race at Savannah which we should like to explain. Immediately after the race, acting on information received from the Hoi-Tan Company, the entrants of the winning Lancia car, we advertised that Panhard oil was used on the winner, and, simultaneously with our announcement, appeared the announcement of one of our competitors to the same effect. We believe it unjust to your publication, to your readers, and especially to ourselves to have these two contradictory statements appear without any explanation.

We therefore wish to state the facts and beg of all to draw their own conclusions, bearing in mind the methods which have been employed by some manufacturers to get their products used on racing cars, and that we have never made any special effort to do this, the present case arising merely as the result of a regular annual contract.

The firm of George A. Haws, manufacturers of Panhard oil, had, and still has, a contract with the Hoi-Tan Company calling for the exclusive use of Panhard oil by them. We have proof that a supply of Panhard oil was shipped by the Hoi-Tan Company to Savannah for the race, and arrived in time for it. The president of the company, and also the Lancia mechanic, assure us that Panhard cans were carried and used on the car during the race, the tops having been cut out to make pouring easy, so that if any other brand was used it was done by emptying our cans and refilling them. The driver of the car, with whom our competitor claims to have had an understanding, has stated, in writing, that he does not know what oil was used, and the Hoi-Tan Company absolutely denies having dealt with anyone but us.

We have reason to believe that our competitor has had similar misunderstandings with other oil houses, and are naturally anxious to have the public set right in this instance at least, thus releasing ourselves from a rather ridiculous position. We certainly would not consider for a moment making a claim to which we did not believe ourselves justly entitled.

New York. GEORGE A. HAWS—H. E. HAWS.

MISTAKEN NOTION WORKED TO A FRAZZLE.

Editor THE AUTOMOBILE:

[1,808.]—I should have been more pleased had you published my letter in full, instead of running the editorial blue streak through some of the most salient points, as for example, the table of carrying capacities. I think it is only fair to me to ask you to publish my last letter in full. The letter, as published, has been mangled beyond recognition. It is very fine to be in a position to dismiss arguments with a wave of the editorial mailed fist and to talk of my taking license with figures. Why don't you publish the table I sent? This proves my argument. Also, I should like to have you answer the question I asked: "How would you proceed to properly select a bearing without a full complement of balls that would be more effective than a bearing with a full complement?"

I quite agree with Mr. Bretz that the carrying capacity of a ball bearing is approximately related to the number of balls. Otherwise, manufacturers would specify carrying capacities to the pound or even to the ounce.

I shall ask you again to publish my last letter without chopping it up. Let's have a square deal, Mr. Editor, and fair play.

New York City. ASHER GOLDEN.

"Letters Interesting and Instructive" are intended to serve a certain useful purpose, and, as the caption implies, the letters have to be edited if they do not conform to the demands in original form. Any such editing should not be construed as indicating "the editorial mailed fist"; on the contrary, it is not to be expected that every correspondent will qualify to the extent of having copy accepted and given space without editing. Take the table, for illustration; it proves nothing, whereas the Stribeck formula, properly interpreted, would be accepted in many quarters, as of some competence. The formula was given space because it does represent something, and if, as you said, the formula is looked upon as a classic (language originally used by Henry Hess in one of his papers before a society), it would seem as if a table out of a catalogue would add but little, if anything, to the value of your statement. Under the circumstances, considering the value of space, the table was left out. So many of your questions were taken up and discussed in the letter by J. S. Bretz, that a mere repetition or further discussion along the same lines would be of no avail. You seem to be imbued with one idea which cannot be encouraged, the purport of which is to induce the editor to engage in a discussion involving the relative merits of the respective makes and types of bearings. There may be some such relation as you intimate, but since both types of bearings are in use to a vast extent it does look like a waste of time to deny the facts. In the selection of bearings for a given undertaking, having decided to use some one type, the way to proceed is to purchase bearings big enough for the work to be done, having in mind the influence that quality of material and workmanship will have upon the result.

To make a comparison then, such as you suggest, would seem to be just about as good practice as the rest of your suggestions, and it is recommended that you take into account the difficulty involved in adding apples to oranges.

SUBSCRIBER WANTS THE "BEST" CAR.

Editor THE AUTOMOBILE:

[1,809.]—Please tell me what you consider the best touring car made for $1,500 or less. I do not care for a speedy car, but I want one that will last a long time in good hands. Also mention what you consider the best magneto and tire equipment to put on the car. A SUBSCRIBER.

Morristown, N. J.

Your question is a hard one to answer for you ask to know the best and, of course, there is no absolute best, that being only a relative term when applied to automobiles. Similarly with the magneto and tires, although in the case of the former, the practically universal adoption of one make should speak volumes in favor of it. Your attitude toward the speed question is a very commendable one.

An Automobile Through LIGURIA

By ~FRANCIS MILTOUN~

OF ALL the Italian gateways, that via the French Riviera and the Mediterranean coast road is the most delightful. Mont Cenis, coming from Paris, cuts the distance considerably, but offers no remarkable interest, save the superb run through Savoie, while the Saint Gothard, a splendid mountain road, is rather roundabout unless one is bound only to the Italian Lakes.

The obvious and most splendid entrance of all from France into Italy is via that superb strip of Mediterranean coastline whose equal for sheer, ravishing beauty is not to be found in all the world. The coast road, the old Roman way from Spezzia to Genoa, and beyond through the Italian and French Rivieras, is bound to become one of the world's greatest automobile thoroughfares, if indeed one may not reckon it such even now. The Italian section is not as good as the French portion, but it is the best seacoast road in Italy. It has a width of 36 feet for the most part, but in places narrows down to half that width, and here and there overhangs a precipice on one side and is half roofed by a shelf of rock on the other.

This makes for picturesqueness and novelty to those who are used only to the broad boulevard like "Routes Nationales" of France, or the leafy lanes of England. There are drawbacks, however—the awful surfaces here and there, and the still more awful exits and entrances of the cities like Genoa, Spezzia and Livorno. But take it all in all the scenic charms are so varied that it is worth the doing.

From Menton in France all the way to Genoa—177 kilometers—the road is a continual rise and fall with sharp turnings and bad going for five, ten or fifteen kilometers at a stretch. Rain, an exceedingly dry spell, an automobile that for the moment is not pulling well, or a cycle of punctures or blow-outs which are apt to be more prevalent here than elsewhere in Europe, can considerably discount one's appreciation of the charms of this otherwise delightful road by the sea.

The combination nearly did for us—the author, the artist and one other—and a level railway crossing (there are seemingly a hundred of them in as many kilometers) nearly brought disaster many times, though fortunately we escaped.

Think of a great tree trunk, like a well-sweep, swinging automatically, or at least pushed by some hidden hand, out over the roadway without a warning of any kind and you will put it down as the most barbaric "safety appliance" ever thought of by civilized man, at least so far as a road obstruction is concerned. It is like the toll-gate bars of old, though here they appear every mile or two and are always half hidden by a nearby turn of the road. One passes close to the danger line only too often. Italy must wake up or keep its level crossing guardians on the *qui vive,* which they are not at the present time.

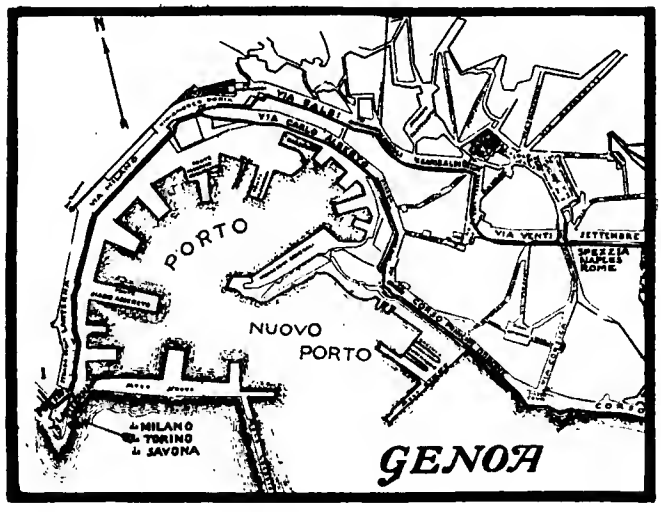
One must hope for the best when traveling in these parts, and if conditions *are* favorable, and all *does* go well, the itinerary should prove delightful. Bordighera and San Remo are mere resorts for semi-invalids and are not worth a live man's consideration, and anyway they do this sort of thing much better in France. Porto Maurizio (Hotel de France) for lunch—which the Italians call *collazione* not *déjeuner,* remember—is better than the resorts further west where one gets imitation Parisian fare only. The town is the most typical and characteristic of Mediterranean fishing ports on the Italian Riviera. It is like Cassis in Provence, only more so, and the fleet of ships in harbor fly the flags of all Mediterranean nations. There are *balancelles* from Malaga and *feluccas* from Barbary, besides the Italian kind of sharp-prowed craft with low-hung latteen rigs, giving the whole scene a cosmopolitan air.

Eastward from Porto Maurizio we set out immediately after lunch, expecting to reach Genoa that night. Fate, those eternal railway crossings and bad roads willed otherwise, and Finale Marina (Albergo Garabalda) was our stopping place that night. Alassio might have held us, but it, too, is a blatant resort in a small way, and we would have none of it.

Just before Alassio, juts out the Capo delle Mele, dividing the Riviera de Ponente into two equal parts. Here everything on the Italian Riviera changes, the geological formation of the soil and the quality of the crops, particularly that of the olive, and for the worse.

Finale Marina is a monumental nonentity. Its site is nothing remarkable save that it is on the seashore, and it has no history worth speaking of, but all the same its quaint, straight streets, its old *palazzo,* its monumental *chiesa,* its fortress and its palm-bordered *quai* make it a delightful stopping place.

Noli, just beyond Finale Marina, is not a stopping place for tourists of convention. An artist who wanted to paint old towers, fortification walls, rooftops and olive groves all in picturesque juxtaposition would not fare so badly here. It's an advantage to be an artist and see many things that others pass by.



HOTELS AND THINGS

Genoa is still a long way off, though its cloud of smoke has hung on the horizon ever since the Capo di Noli was passed. Savona is a miniature Genoa, the third busiest port on the Riviera, coming directly after Genoa and Nice, though the Genoese did their best to strangle its prosperity in the sixteenth century, when they blockaded its harbor and filled the entrance with débris. On a tower on Savona's port is a great statue of the Virgin, before whose shrine the sailor folk say their prayers. Beyond its smoky picturesqueness, its broad flagged streets and its shocking pitfalls of getting in and out of town, Savona is nothing to be remembered of the automobilist.

How One Waits at Railroad Crossings.

We remember it because we waited three-quarters of an hour at a level crossing just before entering the city. The Nord-Sud-Brenner-Rapidé, from Vienna to Nice, bringing a trainload of Franz Joseph's subjects to the sunny Riviera, was nearly an hour late, and the incumbent whose duty it was to open and shut the railway barriers shut them, according to orders, when the train was due, and would only open them after it had passed. Had it run off into the ditch and never arrived we should probably have been waiting there still.

We were not able to reach Genoa for lunch even, owing to this delay, but did very well at Varazza, dining in a vast *salone* which must have seated a couple of hundred people. The proprietor ran a sort of side industry in recruiting Italian immigrants for the "two Americas," as he called the New World. The majority of his clients bought their tickets straight for New York, however—"Nuova Yorka bella citta!"

Cogoletto, between Varazza and Genoa, is another of the apocryphal birthplaces of Columbus, and the house where he was born bears a sufficiently convincing inscription to that effect.

Voltri, a dozen kilometers further on, has for centuries supplied printers all over the world with fine old hand-made and water-marked papers. Paper making, like beer making, depends largely upon the water used in the process, and here the water is of such a specious purity that the shrine of the "Madonna della Aqua Santa," of Voltri is famed throughout all Italy.

Still one does not get to Genoa. The road seems interminable and gets worse all the while, with tramways, ox-carts and five tandem horse trucks. Pegli must be passed, and Pegli for the automobilist is as nothing, though for a fact it is a resort as full of Germans as Hyères is of English. Pegli has a sight in the shape of the Villa Pallavicini, with elaborate gardens, which the Italian residents call a "*meraviglia d'art.*" That judgment depends entirely upon one's individual taste and his ability to express it in words.

Genoa's Awful Main Road.

Genoa, with its awful railway and tramway-lined main road, is a nightmare. Genoa is one of the finest cities of palaces on top of the earth, but the automobilist entering the city via San Pier d'Arena will need a period of repose after circumnavigating the port, past the four hundred year old lighthouse, "La Lanterna," before he does a round of sight-seeing.

Genoa's hotels are of all ranks and all excellencies, some with garages and some without. We found an astonishingly good thing—after half an hour's busy hunting—the Hotel Union, on the Piazza Campetta, whose only access was by a ten-foot alley, a bad hill coming down and a worse one getting out. The F.I.A.T. garage was at least a mile away, but we were glad we came, nevertheless. All things considered, the little Hotel Union at Genoa was about the best thing in the hotel line that we found in Italy, and the garage accommodations, when they were finally located, were superb.

The road out from Genoa is by the magnificent Via Settembre and is a little improvement over that by which we entered, but given a rainy day and no anti-skids and the greasy, slimy pavement, with two lines of tram track all the way to Nervi, and the driver of an automobile will have considerable excitement and some risk in getting out of town. Nervi is what the guide books call "a mild winter station for invalids." It is that, but it possesses no shrines for sentimental travelers save the garden of the Villa Grapello, and the hotels hang out signs of Pilsener and Munich beer instead of tea and whiskey. The omnific German has appropriated all the Italian Riviera, as the Americans and English have the Côte d'Azur.

Why German Aspect Is Good.

The only really good thing in the way of a resort hereabouts is the little bunch of towns clustered around the mountain promontory of Portofino. Here, too, the whole aspect is German, but that's a good thing in itself. It keeps down prices. The German en tour doesn't squander his gold; he asks the price beforehand and gets as good as we do, perhaps better, and for less money. From Recco the coast road climbs up the mountain side to Portofino-Kulm, but it is nothing difficult, and the road

ON THE FRONTIER

DOGANA DOUANE

here is the best on the whole Italian itinerary. Portofino is reputedly the most beautiful spot on all the Italian Reviera. The honors lie easily on its head, and the title "Queen of the Mediterrancan" is only in dispute between the cities of Portofino and Monaco.

Ten minutes in an automobile, leaving the grand route at Santa Margharita and continuing by a little side road which rises and falls and twists and turns at the very edge of the shore, and one passes the ancient monastery of Cervara, where François Premier was confined for a time by Charles Quint after he had lost "all save honor" at the battle of Pavia. Almost before he knows it the automobilist drops down into Portofino and takes his choice of the Hotel Splendid, with prices according to its name, or the Hotel Piccolo, also with prices in accord with its nomenclature.

Rapallo, on the mainland, is a typical little Ligurian seaport, with an old watch-tower, or donjon, a defence of the days when every little coast town lived in a tremble for fear of the descent upon its quais of some pirate hoard from Barbary. The Hotel de l'Europe (with a French name, albeit that it is an Italian albergo through and through) is a seedy-looking seaside hotel which caters for the automobilist well enough, though its garage accommodation is limited. In its "Libro d'Oro," where you sign your name as from Kalamazoo or Kickapoo, you also note that Queen Margharetа has inscribed hers, as well as various other lesser lights of the European noblesse.

From Rapallo to Chiavari are thickly peopled hillsides, with gleaming white houses and square whitewashed campaniles of churches everywhere peeping from among the olive trees and vines. Chiavari is one of the ancient towns of the Genoese territory, built up in the genuinely romantic medieval fashion, with tall houses stilted on great stone arcades and rising like skyscrapers. The streets of Chiavari are more like canyons than anything east of Wall Street. The specialty of Chiavari is the making of chairs, though where they all go to it is hard to say, as no one ever saw the like of these particular chairs elsewhere.

Sestri-Levante is also an up-and-coming resort, with numerous hotels and pensions, a delightful situation, a mild climate and no architectural monuments worth speaking of, much less writing of. It is the last of the Riviera resorts as one goes east.

The road now deserts the shore and runs the last sixty kilometers inland by the Coll di Bracco. It climbs up and up, like the road over the Col de Quatre Chemins back of Nice, with the sea frequently in sight below the sloping olive orchards. It grimps along in places on a mere terrace or shelf of rock, and as one headland juts out into the sea farther than another the farther away from the actual shore runs the road.

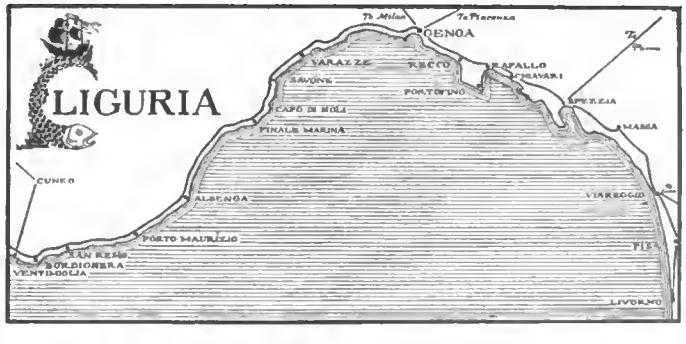
At the crest, at the actual mountain pass, seven hundred odd meters above the sea, the road is still twisting and turning on itself until Bracco, the old diligence station, is reached. Even here the view of the distant sea and the coast villages is still superb. Down drops the road by gentle sweeps and curves to Borghetto and finally Spezzia.

Out from Spezzia the road grows worse and worse until, in a dozen or twenty kilometers, it descends into a mere slough. It is, the writer verily believes, the worst road in Europe.

After a couple of hours of brain- and nerve-racking driving, and heartbreaking fears for your automobile, you will be glad enough to lunch in the garden of the Hotel Massa at Massa, when, perhaps, you will have the courage to proceed further.

You pass Viareggio as fast as the road will allow, and sweep at last on to a good stretch of highway which draws slowly up over the plain and finally around Pisa's lone leaning tower, its duomo, and its campo santo. It is with a real relief that you at last settle down in the Albergo Nettuno at Pisa, remodeled out of the old Palazzo Agostini.

Garage accommodation is limited at the Albergo Nettuno, and you pay two or three francs a night for it, but as far as it goes it is satisfactory. Have nothing to do with the local mechanic or his garage. Buy your benzina (as the Italian calls gasoline) at a drug store or a grocer's, or you will get unmercifully stuck. You ought to pay fourteen francs for a five-gallon can, say thirteen kilos, but you may pay twenty if you don't watch out.



THE AUTOMOBILE

FUEL ECONOMY IS A LIVE TOPIC.

The rapidly increasing price of motor fuels, taken in conjunction with their rapidly decreasing quality, is giving the progressive manufacturer plenty of food for thought, and should be, if it is not actually, the big point for thought on commercial motor trucks. In this connection truck builders should be working on cheaper fuels and bringing out engines especially adapted to burn these fuels, for the answer to this fuel question is bound to become more and more difficult as time passes and as the number of vehicles in commission increases.

Aside from the agitation of a few years ago relative to denatured alcohol, which quickly died down, nothing has been done. On the other side of the Atlantic this question is even now assuming large proportions, and the manufacturers are showing that they are alive to its future possibilities by experimenting with other fuels. Thus, in a recent long-distance trial from Paris to Versailles and return, two 40-horsepower trucks of the same make, weighing with load over 19,000 pounds, were fitted to burn two different fuels. One of these used gasoline, while the other was fired with naphthalene, used in solid blocks or cakes, gasoline being resorted to for starting only. Naphthalene is a white substance of very little use. It is a byproduct of the destructive distillation of coal as practiced by the gas companies. As such, it was thrown away, until three years ago, when a use was found to pay for saving it.

The results are of more than passing interest. The truck operating on gasoline consumed for the whole trip an average of 16 liters, costing 14.2 francs ($2.75) per hour, while the other used up 29.2 kilograms of naphthalene, worth 4.22 francs for running and 3.2 liters of gasoline, costing 1.18 francs for starting. The total, then, for the latter was 5.4 francs ($1.04) per hour. These figures are based on the retail prices paid at Paris, which, reduced to English units, amount to 65 cents per gallon for gasoline and 12 1-2 cents per pound for naphthalene. The results, showing that fuel cost, using gasoline, may be improved upon to the extent of 62 per cent., or, looked at from the other side, showing a loss of 162 per cent., should afford our progressive manufacturers opportunity for reflection.

* * *

MAKING LAWS FOR AUTOMOBILING.

Despite occasional indications of unprogressiveness in various parts of the country, the general tendency is towards more rational and sane legislation in regard to the running of automobiles. Once upon a time the automobilist had to accept with as good grace as he could summon whatever laws were made for his "benefit." But he has taken a lesson from the experiences of the lowly cyclist, who grew in numbers until the "servants of the people" learned to respect his rights and wishes, of course providing there was no interference with the real rights of other road users.

While it is an unfortunate fact that not more than one in a score of automobilists joins his local club or otherwise becomes identified with organized efforts to bring about a better state of affairs, it has followed that with the instituting of clubs in localities, conditions have bettered, as has been the same result in the State when the clubs have worked as a unit. It follows as a natural sequence that the State bodies should be associated, which gives the reason for the existence of the American Automobile Association.

No matter if differences of opinion may arise as to the actions and rulings of any one of its boards, the national association is a necessity of the hour and deserves the support which it is obtaining from the amateur owner, as well as from the automobile trade itself. If the best way to insure peace is to prepare for war, it is likewise true that with the automobilists thoroughly organized there will be less hostility from agitated legislators, who are ever wont to be influenced by the greatest and most influential number of voters.

If the automobilist has his say in the making of the law, he owes it to himself as a good citizen to obey, and, as far as lies in his power, to compel others of his kind to obey the law in which he has had a hand in the making. Therein lies an excellent characteristic of the Englishman, who insists that he must help make the law, but, once having made it, he obeys it as though it were a religion closest and dearest to his heart.

JERSEYMEN HOLD SIXTH ANNUAL BANQUET.

NEWARK, N. J., March 22.—No autoing organization in the entire country wields more influence and shows more progressiveness than the New Jersey Automobile and Motor Club, and its sixth annual banquet, held Thursday night last in Krueger's big auditorium, proved the banner event of the kind in the history of the body. Nearly three hundred faced President Paul E. Heller when he introduced the first speaker of the evening. Preceding this feature of the function there had been an inning of songs, some of which were composed for the occasion, and all present participated in the singing.

H. D. Bowman made a most efficient chairman of the committee in charge, which included A. B. LeMassena, James R. English, J. H. Wood, W. C. Crosby, H. A. Bonnell, Guido O. Greebe, G. H. Simonds, W. S. Sheppard, Albert Schurr, and Charles W. Baker.

First of the speakers of the evening came former United States Senator James Smith, Jr., whose topic was "The Automobile as a Civilizing Influence." In the course of his remarks he said:

"When the automobile was first introduced like many others, I looked upon it with great disfavor. This was because we were led to believe that it was a vehicle designed only for speed and had come to replace that noble animal, the horse. This feeling has all changd, however, and we now see the automobile in its right light. A motor car when properly handled is one of the most joyous things of life. While we have made wonderful progress with the auto in the past it has a greater future. There is no recreation that gives more health, vigor, enjoyment and beneficial results than automobiling. Every improvement that tends to make life pleasant and distances shorter is an improvement that brings the people close together and makes of them better citizens."

Ex-Congressman L. Irving Handy, of Delaware, who supplied the humor of the occasion, said that he liked banquets, for he was built that way, and was pleased with the opportunity to come to such a spread as he had before him. The ex-congressman belongs in the heavy-weight class. A. G. Batchelder's topic was "Some Autoing Reminiscences"; J. B. R. Smith, State commissioner of motor vehicles, did some "Looking Forward"; and Vivian M. Lewis had as his topic "Our State."

Assemblyman Austen Colgate, who has not hesitated to espouse the cause of the automobilist at Trenton, was a popular speaker, whose views met with unanimous approval. Mayor Haussling referred to the good roads of New Jersey and said that there were none better anywhere.

There was considerable reference to the present treatment of outside automobilists, especially in the matter of reciprocity, and if the matter could have been left to the vote of those present, the automobilists of the other States would have no difficulty in entering the commonwealth of New Jersey as freely as the Jerseymen now visit New York and other States.

NEWSPAPERS INSTALL MOTOR TRUCK SERVICE.

NEW YORK CITY, March 22.—The New York *Herald* and the *Evening Telegram* to-day installed an automobile delivery service of five cars, which will be used to distribute the papers to retail and branch offices. This installation will be followed by the addition of as many more next week, and the total, taken with the number of heavy trucks now in the service, will give these two papers one of the largest installations in the country and easily the largest of any newspaper. In the newspaper business, time is essentially money, and the prime idea back of this new move is the possible saving of time which the service is expected to make.

The cars are of the Renault make, the chassis and tires only being imported, while the bodies were made in New York City. The cars are of two types, two-ton trucks which have four-cylinder engines and one-ton machines with two-cylinder motors. The former weigh 3,400 pounds and the rating is 14-20 horsepower. On the other hand, the smaller cars only weight 2,200 pounds and deliver but 10-14 horsepower. A feature of these cars is the use of twin pneumatic tires on the rear wheels of both trucks.

NEW LAMP COMPANY FORMED IN DETROIT.

DETROIT, March 22.—The latest addition to the long list of automobile and accessory manufacturers claiming Detroit as home, is one that will help materially to add to the fame of the City of the Straits. This is the C. M. Hall Lamp Company, and is composed of a small group of the city's most influential business men. As soon as the temporary organization had been formed, officers were elected as follows:

John W. Leggett, president; Thomas J. Wetzel, vice-president; J. F. Hartz, treasurer; C. M. Hall, secretary and general manager; and with these, D. M. Newbro, of the Herpicide Company; J. L. McDonell, superintendent of the House of Correction; and E. H. Broadwell, vice-president of the Fisk Rubber Company, will serve on the board of directors.

The company will manufacture high-grade automobile lamps only, including acetylene, electric, and oil lamps of exclusive patterns covered by patents. Among others is what is known as a "dimmer," which partly shuts off the light from a headlight when necessitated by city or other ordinances, and saves the annoyance of stopping and extinguishing the lamp.

Mr. Hall, the manager, was for five years with the Badger Brass Company, as salesman, while many of the others interested in the concern have also been with this company. The capital of $150,000 was all subscribed and most of it paid in, so that preparations were made to start business at once, this including the purchase of a two-story building, 60 by 180, on Rivard street.

DEATH OF HENRY TIMKEN, IN CALIFORNIA.

CANTON, O., March 22.—It is with deep regret that the Timken Roller Bearing Axle Company, of this city, announces the death of its president, Henry Timken, which occurred on March 16, at San Diego, Cal. Despite his advanced age, 76, his death was a surprise to his friends, as he has been unusually sturdy and rugged, and his illness lasted but a few days. He was buried in San Diego yesterday, and on Saturday the factory in this city was shut down in tribute to his memory. Mrs. Timken died last December.

A pioneer in the manufacture of carriage, wagon and later automobile roller bearings, Mr. Timken began his business career in St. Louis, when that city had but 25,000 inhabitants. His first patent was the Timken spring, which he manufactured and put upon the market, followed by his own invention of the roller bearing which bears his name. He was one of the first men to be elected to an office in the National Carriage Builders' Association, and for years served it with the same ability and faithfulness which he gave to his own affairs. After a successful business career of more than 45 years he retired and went to live in San Diego, where he has spent the last 12 years.

FERNAND RENAULT DIES IN FRANCE.

NEW YORK, March 22.—Fernand Renault, one of the famous Renault brothers, the makers of the Renault automobiles, died to-day at his home in Paris, according to a cablegram received by Paul Lacroix, the manager of Renault Frères Selling Branch. Mr. Renault had been in poor health for some time, and it was just announced that he had retired from active participation in the affairs of the big concern on the Seine. He was the oldest of the three brothers who first formed the company, being born in Paris on November 28, 1864, was a copartner in the firm, vice-president of the Automobile Section of the Syndical Chamber of the A. C. F., and president of the Renault Frères Selling Branch which has charge of sales in this country and Cuba.

The death of Fernand Renault leaves but one surviving member of the trio, Louis Renault, the youngest, who was born in 1877, who is also a copartner in the firm, and one of the most prominent figures in Continental automobiling affairs. Marcel Renault, the third of the brothers, and the one between the other two in age, died two days after an accident in the disastrous Paris-Madrid race in 1903.

Franklin Non-Stop Engine Shown to Be Cool.

Maxwell Junior of Philadelphia, Non-Stop, Performer.

NOVEL EVIDENCE THAT FRANKLIN KEPT COOL.

"'Tain't hot; if 'twas I'd move." So read a sign displayed recently by a small colored boy, seated upon the hood of a 28-horsepower Franklin touring car, during a sixty-hour non-stop run of the car's engine in Kansas City. Throughout the daylight hours of the test he stayed on his perch, and so far was the air-cooled engine from overheating that it failed to keep the boy comfortable, and he wrapped himself in a blanket to keep warm.

The test was made in the street in front of the headquarters of the Franklin Motor Car Company. It began Monday morning and did not end until Wednesday night; during this time only 1 1-2 gallons of oil and 28 gallons of gasoline were used, although the motor was run at a good rate from start to finish. At all times during the sixty hours the cylinders of the engine were so cool that they could be touched with the hand. A sixty-mile as well as a sixty-hour test was made. In running the sixty miles the car carried five people about Kansas City, the run being made in eleven hours at the rate of 5 5-11 miles an hour. The entire course was covered on the low speed, which is geared at twelve to one. Had the run been made on the high speed with the engine making the same number of turns, the distance covered would have been 225 miles.

SYRACUSE SHOW SPACE MUCH IN DEMAND.

SYRACUSE, N. Y., March 22.—With every inch of space in the State Armory Building already taken, automobile makers and dealers are still clamoring to Chairman Kerr of the Show Committee, for space at the local automobile show, which will be opened by Mayor Alan C. Forbes on Thursday. Over 100 applications came in and twice as large a building could have been used, though the armory is the largest available in the city.

Fourteen firms and individuals are allotted space on the main floor and 100 different styles of cars will be shown. The basement will be given over to the showing of accessories, there being a score of exhibitors in this class. Syracuse is fast becoming an automobile center and every factory of importance in the country has been asked to send famous cars and polished chasis.

ALABAMA WILL HAVE AN AUTO FACTORY.

BIRMINGHAM, ALA., March 22.—Plans have been made in this city for the early establishment of an automobile factory to build six-cylinder cars, and the first complete factory of its kind in this State. As yet, not all of the details have been completed, but it is known that the product will be called the "Great Southern Six," and will be sold at a moderate price. The concern will be incorporated and capitalized at about $250,000. The only official known definitely is E. F. Enslen, who will be the secretary-treasurer, and he states that full information will be ready in a week. The location of the plant will be on Avenue B.

MAXWELL, JR., NON-STOP RUNS TO PITTSBURG.

PHILADELPHIA, March 22.—Finishing its 2,000-mile non-stop task early last Friday morning in 5 days 16 hours and 45 minutes, the little Maxwell Junior runabout, which during the better part of last week tirelessly ate up the miles, up and down Broad street, was reshod with Ajax tires, and, without stopping the engine, was headed for Pittsburg, where it will be put on exhibition at the show to be held next week. The little car averaged a trifle over 24 miles per gallon of gasoline, and maintained a schedule throughout of a little less than 15 miles an hour. Relays of drivers from Lancaster, Harrisburg and other intermediate points took the little plugger across the mountains to the Smoky City.

BOSTON MAXWELL AFTER NON-STOP RECORDS.

BOSTON, March 24.—In an attempt to establish the world's record for non-motor-stop runs, a Maxwell touring car of 30 horsepower, at noon to-day had traveled 2,606 miles of the 10,000 which it has started out to cover, its engine humming merrily, and no signs of trouble. The machine was started at 10 o'clock last Thursday morning from the clubrooms of the Bay State A. A., when President L. R. Speare, of the A. A. A. and the Bay State A. A., cranked it, and it was driven off by Lucius J. Tyler of the Maxwell-Briscoe-Boston.

Under the direction of the local Maxwell dealers, and the auspices of the Bay State A. A., this contest will be run on the roads surrounding this city. Mr. Tyler, accompanied by C. E. Goldthwaite, and Adam Schneider of the Maxwell factory drove the car the first day two round trips over the route to Worcester and return, and then was succeeded at the wheel by Ralph Coburn of the local branch, who was accompanied by Arthur See and Joseph George of the factory. The third relief was composed of William S. Simonds of the Boston branch, Ellery Wright and C. F. Lawrence. Before the start all the drivers and observers were sworn to observe the rules of the test.

The first 1,000 miles of the journey was completed when the car finished its twelfth round trip to Worcester and return. It is planned to continue on the Worcester route for several days more and then to change the route to Providence or Newburyport. The car is equipped with Ajax tires, on demountable rims.

WARNER COMPANY CLAIMS AN INFRINGEMENT.

BELOIT, WIS., March 22.—The Warner Instrument Company, manufacturers of Warner Auto-Meters, has announced the institution of a suit against the Stewart & Clark Manufacturing Company, of Chicago, claiming infringement by the latter. The Warner company holds a patent, No. 745,468, granted December 1, 1903, on magnetic speed indicators, and it claims that the Chicago concern is now making one with magnetic action, thereby infringing upon Warner rights.

INDIANAPOLIS HAVING SPRING CELEBRATION.

INDIANAPOLIS, March 22.—Automobile manufacturers and dealers of this city are celebrating their annual spring opening week, beginning with to-day, exhibiting new models, and joining with each other in festivities, which will tend to arouse interest throughout this section of the country.

The event is held under the auspices of the Indianapolis Automobile Trade Association, which is affiliated with the Automobile Club of Indiana. There are special features for each day, and the city authorities have united to make the week a successful one. To-morrow there will be a tire-changing contest, for clincher, quick detachable, and demountable rims, and a ladies' egg race. Both of these events will be held on the North Capitol avenue boulevard, the Board of Park Commissioners having given special permission. On Wednesday the feature will be a parade, in which several hundred cars will participate. Mounted bicycle officers will lead, followed by the several cars in municipal service, carrying city officials. Behind these will come a Rapid truck, carrying the Indianapolis Military Band, and trucks carrying children from the orphan asylums. Then will come the 1909 models of the different dealers and manufacturers.

The closing feature will be a banquet, Saturday night, at the Denison Hotel, and Mayor Charles A. Bookwalter will be one of the principal speakers.

The general show week committee is composed of B. W. Twyman, Motor Car Sales Co., chairman; F. I. Willis, Willis-Haywood-Holcomb Co.; F. L. Moore, Fisher Automobile Co.; D. B. Sullivan, Indianapolis Automobile Co., and Cecil E. Gibson, Gibson Automobile Co. Other committees are: Press committee: P. D. Stubbs, Overland Automobile Co., chairman; A. R. Kling, Indiana Sportsman; Ray Holcomb, Willis-Haywood-Holcomb Co. Parade committee: F. I. Willis, Willis-Haywood-Holcomb Co., chairman; Paul Smith, Indianapolis Motor Car Co.; Olin S. Peck, Cadillac Co., of Indiana. Contest committee: F. L. Moore, Fisher Automobile Co., chairman; Harry Freeman, Finch & Freeman; George Weidley, Premier Motor Manufacturing Co. Entertainment committee: Howard Marmon, Nordyke and Marmon Co., chairman; Charles R. Newby, State Automobile Co.; R. H. Losey, Buick-Losey Co.; W. H. Brown, Overland Automobile Co.

ACRE OF SPACE USED BY TOLEDO SHOW.

TOLEDO, O., March 22.—With an acre of floor space, in the gaily decorated and brilliantly illuminated Coliseum, devoted to the exhibition of over eighty automobiles, and samples of accessories arranged around the balconies, the third annual automobile show held in Toledo, was this evening opened by Mayor Brand Whitlock. In the eighteen booths dividing the main floor, all of the dealers in this city have for the week placed the latest models of their cars, and for the first time since automobile shows were undertaken here, are a unit in supporting the annual function, a condition brought about by the organization of the Toledo Automobile Dealers' Association.

With all of the preceding shows of the season lending new ideas, those in charge of the decorations have tried to combine the best features seen in other cities, with some distinctive ones planned here. The result is a wonderfully beautiful hall, where pastoral scenes have been combined with those of forests, fourteen large forest trees having been brought into requisition.

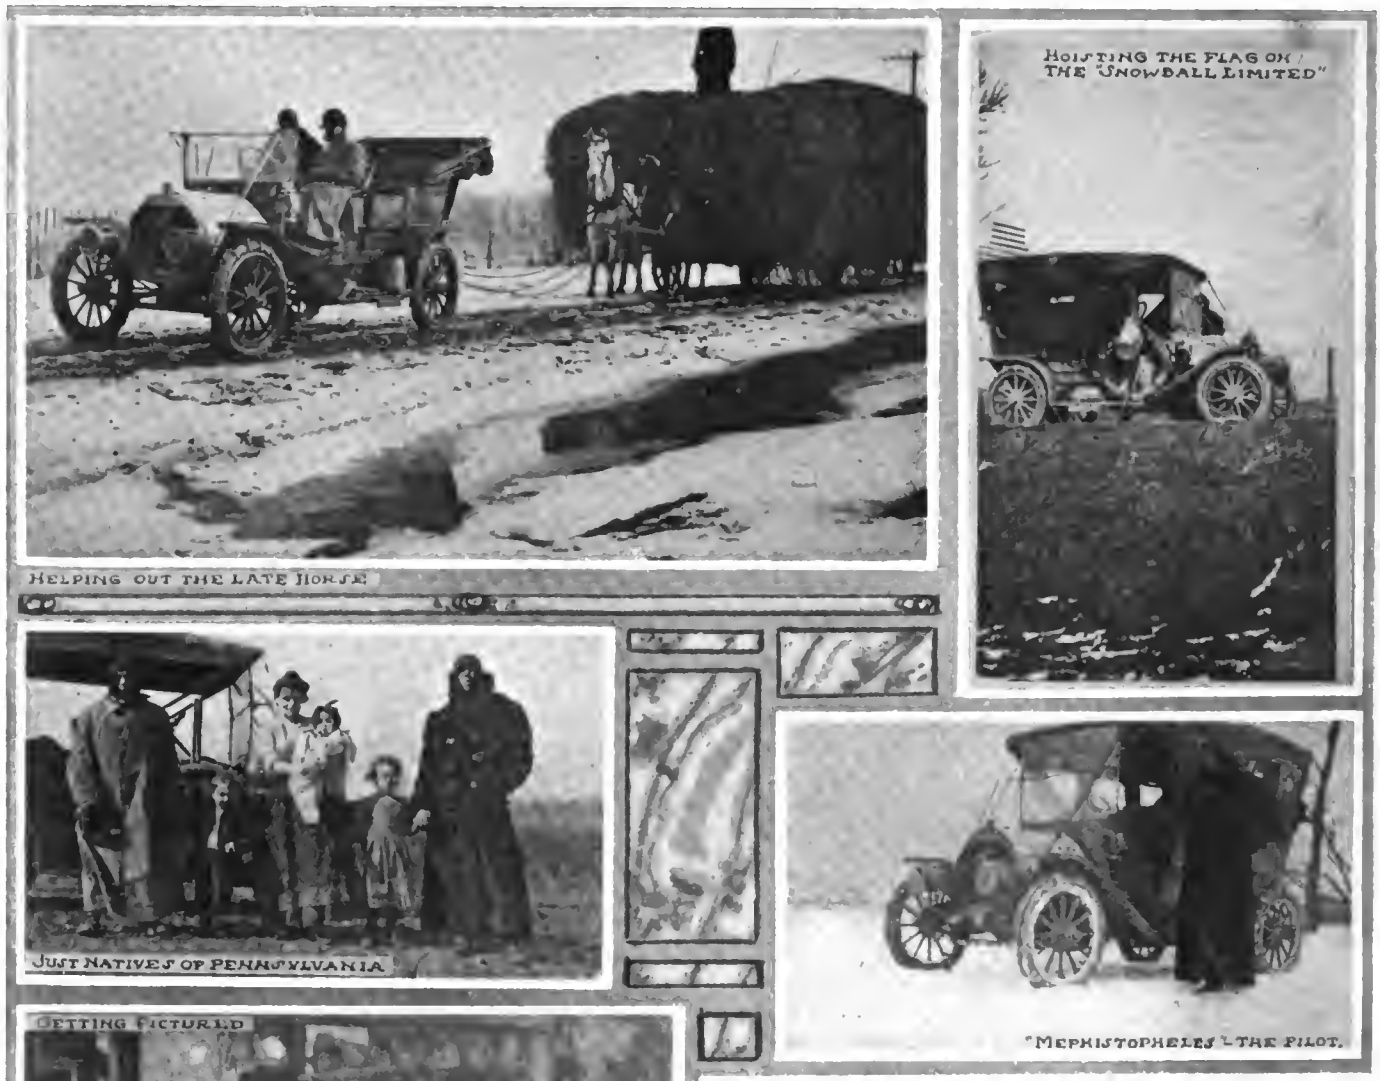
The attendance this evening was greater than expected, and it is believed that the show will be an important one throughout this section of Ohio. It has been extensively advertised, and a great many small dealers, as well as owners, from out of the city have expressed their intentions of visiting the exhibition. In addition, the event occurs during the annual opening week of all Toledo merchants. The newly formed trade association has been a prime mover in the preparations, and its officers have been especially active. They are: president, A. A. Atwood; vice-president, W. H. McIntyre; secretary, S. C. Fisk; treasurer, E. A. Kirk. The concerns exhibiting autos follow:

Gamble Motor Car Co., Stearns, Peerless, Baker electric, Rauch & Lang electric; Atwood Automobile Co., Premier, Regal, Stoddard-Dayton, Velie, Overland, Waverly electric; Lichtie Automobile Co., Winton, Cadillac; Standard Garage Co., Brush, Hupmobile, Jewel, Ford; Union Supply Co., Stevens-Duryea, Chalmers-Detroit, Pierce-Arrow; Roberts-Toledo Auto Co., Ford; Central Auto Co., Maxwell, Mitchell; Olds Motor Works, Oldsmobile; Buick Motor Co., Buick; Banting Automobile Co., Carter Car; Kirk Bros. Automobile Co., Thomas, Knox, Studebaker, E-M-F, Columbus Electric; L. L. Blood, Detroit electric, Jackson; The White Co., White steamers; Apperson-Toledo Co., Apperson-Toledo; Harry Overmeyer, Glide; MacInnis Bros., MacInnis cars; Peter J. Lune, Gramm-Logan; H. J. Adams, Reo, KisselKar.

White and Maxwell Automobiles Take Pacemaking Part in Notable Athletic Stunts.

Pugilist Jim Jeffries tries a practice run in New York suburbs, conveyed by a White steam touring car.

Edward Payson Weston, the famous pedestrian, on his walk to the Pacific Coast, is accompanied by a Maxwell touring car.



JUST as "time and tide wait for no man," so "rain and mud have no regard for automobilists," according to the crew of the Regal "Snowball Limited," which recently plowed through the blizzard, from Detroit to Syracuse, N. Y., and thereby proved itself capable of running under the most trying conditions, and winning an interesting wager. During the automobile show in the "City of the Straits," George D. Wilcox, of the Mora Sales Agency, of Syracuse, N. Y., remarked that it would be impossible for a moderate-priced car to make a first-class endurance run over roads that were considered impassable, and he was promptly challenged by a Regal Motor Car Company representative.

The wager was that Mr. Wilcox, selecting any car in the Regal factory, should start, with a driver, for Syracuse, and if the car made good, should take the agency for the car in central New York, contracting for 25 machines. If, on the other hand, the car gave any trouble en route, or failed to reach its destination, the Regal company would stand the expense of the trip. The start was at noon on Washington's Birthday.

The roads were terrible all through the trip, the car taking on, hour by hour, a deep coating of mud, snow and ice, and the crews sharing in the same dressing. Toledo was reached through a sea of bottomless mud at nine o'clock that night, after driving for 126 miles on low gear without overheating. The next day, running to Cleveland, first a lake had to be forded and the rain was fast thawing out the mud, so the "Snowball Limited," as it was called, met unusual conditions. All through Ohio there were telegraph poles and trees across the roads, soft swamps to be crossed, tires to be changed, and at Fremont the little car had to take to trolley tracks and bridge, to cross a river, where the road was minus a bridge. That night was spent in a barn, and Elyria was reached before noon on Wednesday, by which time the car resembled a steam shovel at work excavating roads. With 167 miles to the good the party, consisting of Mr. Wilcox, William Smith, who drove, and Richard Byrne, passenger, reached Cleveland at one o'clock on Thursday, and pushed through that afternoon to Ashtabula.

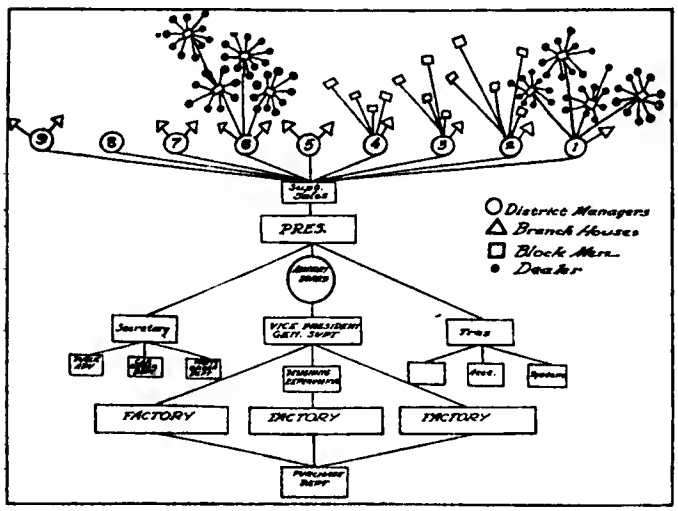
On Friday morning an early start was made for Erie, but at 3 o'clock that afternoon, still fifteen miles from the Pennsylvania city, the party was out of new tires, having used up six new shoes that morning, and a delay occasioned until others were secured, so that the Regal was not headed toward Buffalo until Saturday morning, when a blinding snowstorm was holding forth: 100 miles was covered in 12 hours to Buffalo, and the crew determined to push on to Batavia, which was reached at 10:30 p. m. Batavia to Auburn, via Canandaigua, was sufficient for a Sunday run, and at noon Monday the car reached Syracuse in perfect condition, not an adjustment having been made.

HOW ONE CONCERN SYSTEMATIZES ITS SELLING

By C. W. KELSEY.

CAPTAINS of trade sit up and marvel at the growth of the automobile industry, the gigantic strides direct the attention of Wall street, the throbbing center of the United States Steel Corporation, and the small army of banks throughout the country. The labor world thinks keenly upon the problem, labor leaders realize that the wave of financial depression that swept over the country, and was nearly a year in passing, would have been infinitely worse had it not been for this new manufacturing enterprise, for the larger and stronger companies felt not the financial stringency, and the demand for their cars was greater than ever, with the consequent results that large contributory companies, the manufacturers of steel, aluminum, bronze, leather and rubber goods were all able to keep their plants going on account of this new demand. Even the billion-dollar steel corporation is permitted not to overawe the automobile industry.

Experts who are getting at the roots of things in their efforts to present data to the Ways and Means Committee of Congress, to make able presentation in the interminable arguments over tariff, and the protection of the American automobile maker against the European rival, startle everybody but themselves with the totals they dig up. It is estimated that, with the stupendous development of the American automobile industry, there are now invested in plants for automobile building, and all necessary kindred industries, such as the plants making accessories, leather for machines, parts, etc., more than $300,000.



Factory Organization Diagrammatically Shown.

Less than a decade ago the automobile industry in the United States was an apology. The maker of an automobile at that time unhesitatingly paid tribute to Europe. France was the center of the motor universe, with Germany playing a good eccentric second, but in five years the United States began to be a factor of no mean consequence. "Beat out France in the amount of automobiles turned out" was the slogan. But there were "doubting Thomases," who considered this an almost impossible task. In 1902 there were fifty-one firms in the industry in the United States, and eighteen of them discontinued business, leaving thirty-three plants for the nucleus of the 1903 business. This number was increased to seventy-four, although thirty firms fell by the wayside in the race to get into the world-wide movement for producing automobiles. Fifty-four new concerns essayed entering the field in 1904, and forty gave up the ghost, leaving eighty-eight firms in the trade at the end of the year. In 1905 fifty-one new companies came into being, and thirty-eight discontinued, leaving 101 for the opening of 1906. During the latter year there were forty-three new concerns, while only twenty-nine gave up the sponge, leaving 115 concerns in business. At the end of 1907 there were 166 firms in the industry. There are more than 250 firms now engaged in the industry, and capital is seeking a place in them as well as in the embryonic firms that soon may be launched.

Estimates based on the most conservative figures indicate that there will be added to the visible supply of automobiles during 1909 by these United States concerns no fewer than 90,000 automobiles. "And the commercial vehicle problem has only been scratched on its surface at that," remarked the manufacturer of pleasure vehicles. "We dislike to attempt to mark the boundaries of the motor industry when the commercial car comes into its own."

Automobiles are factors in the daily life of the nation—the schoolboy recognizes this as an axiom. The automobile industry, in itself such an important adjunct of that billion-dollar staple industry—the Steel Corporation—becomes daily more of a twin to the latter. For that reason, captains of industry pause and think hard before they attempt to prognosticate the probable gigantic proportions that both are likely to achieve. The nation has changed its mind absolutely inside of a decade about the automobile being for the rich. It is a feature of the political economy that makes for more economies and more pleasure—it's the greatest necessity of modern times.

Realizing that the keynote of the industry had become "the maximum of motors for the maximum number of people," some manufacturers concentrated the efforts of their designers on products that would appeal to the masses. The result—the medium-priced car. Another result—the enterprising makers who read the handwriting on the wall have gone forward on a wave of success. It is no exaggeration to say that their problems now have become those of enlarged plants, night and day shifts, and purchasing supplies for the use of the busy plants. Seriously, if the business continues to grow with such leaps and bounds the makers of the cars that the people most desire will have to give more thought to supplies. Any momentary paralysis of the allied steel industries would mean serious trouble in the great consuming centers of the makers of popular-priced cars.

The larger organizations correctly interpreted the course of growth from the start. It was the judgment of the factors of these organizations' policies adhered to strictly, and designs produced by competent engineers, combined with a perfection of system as intricate as the United States postal service, yet as effective as a small organization, resulted in the Maxwell-Briscoe Motor Company becoming the largest manufacturers of automobiles in the world. So enormous have the proportions of the automobile industry become that only by meeting them with prodigious organization can a motor manufacturer expect to keep up with the procession, to say nothing of leading it. The strongest links of the automobile organization, in all the phases of the industry, must be as strong as those of the steel corporation. There must be no weak links. In the Maxwell-Briscoe Motor Company there are no weak links. The organization is such that the factory units may be increased in blocks of two, four, ten or a dozen, and still the output may be put where it will be assimilated by the market—or, to be correct, the people.

What would you say if I should tell you that the president of the Maxwell-Briscoe Company, or any leading factor in the department executive work, could not only tell where every Maxwell car is, and who owns it, but also give a short history of the manner in which the machine was assimilated in the market? All this could be done upon a moment's notice. If the inquisitive critic wished to further test the completeness of the Maxwell-Briscoe system, he could ask other questions. He could find out what parts and repairs were needed, the cause of the repairs, and how the matters were adjusted. Anything that passes either through or out of a Maxwell factory leaves its imprint on the records. They know what is doing, and what everybody should

do. The system of an army head constantly in touch with his chiefs of corps, divisions, brigades, etc., is no more effective than that which obtains in this factory. The executive, his immediate aids, and the advisory board are at all times in direct touch with every department. The factories themselves come under the direct supervision of the vice-president, who also is chief engineer and designer.

Suppose, for instance, that a year's work is to be planned. The advisory board is called into session. The district managers, superintendents of sales, secretary, treasurer, general superintendent, and vice-president compose this effective board. The president presides. At this important meeting the policy of the company is outlined. This is a tremendous advantage, for, heeding the district managers, who are in touch with the pulse of the trade, the factory is able to produce the type of car that the public demands. In short, here is reflected not only the judgment of one man, or several, but the desires of the American public, voiced through hundreds of dealers.

Following the recommendations of this advisory board, the chief engineer, together with the designing department, work the new models on paper, after which they are built in the experimental department and thoroughly proved, until every detail has been worked out and found satisfactory. Orders are then given to the purchasing department for material. Each of the several factories work in competition to produce the best results and to stimulate this, prizes are offered to the leading superintendent and foremen. Records are kept in the car-order department showing the rate at which cars are coming through at each factory, each department at the same time keeping an accurate account of the cost of each part; also the cost of the completed car. After a thorough testing on the road, the cars are repainted, equipped and shipped the same day they are completed.

In connection with the manufacturing department is the sales department, which must be built on lines broad enough to market a great output in the most economical manner. The building up of the sales department of a big automobile plant reads almost like a fairy story. The sales department logically comes under the direct supervision of the president, who is assisted by the superintendent of sales. Under these two men are what are known as district managers, each of which controls a certain section of the country. In the principal cities of each department are located branch houses, which are directly controlled through the district manager by the parent company. Following out the system still further, under each district manager are a number of men known as block men, and under each block man are from twelve to twenty dealers; part of the work of these block men is to circulate among these dealers, assisting them when possible and seeing that the cars are being sold in accordance with the policy of the company; that prices are not cut, and that customers are treated with fairness and consideration. Such block men make daily reports to their chiefs, the district managers, who in turn make weekly reports to the factory, where complete records are filed. Thus the moment a car is sold the name of the owner is recorded, the name of the dealer who sold it, and the number of the car is put on the card.

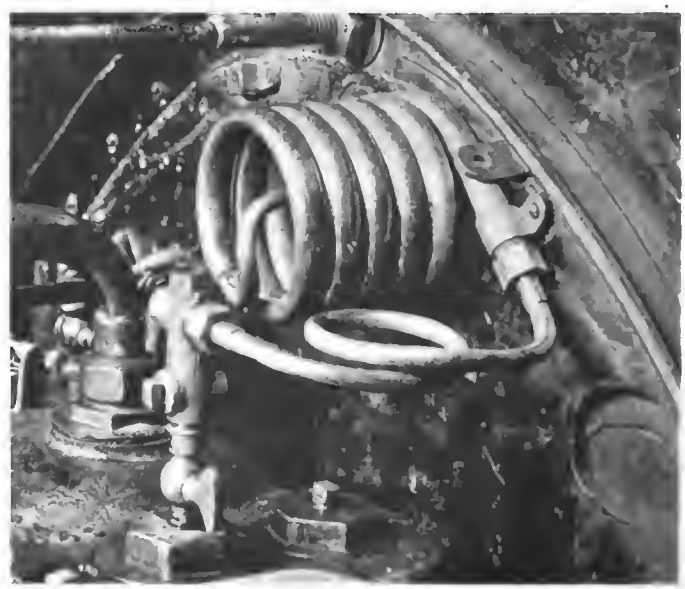
Believing that competition keeps all departments of the organization working at its highest efficiency, every dealer works in competition with his neighbor, the branch-house managers in competition with themselves, while still higher up the ladder each district manager fights it out with his neighbor to see who shall lead. Every two weeks a pamphlet is issued, showing the relative standing of every member of the sales organization, with a statement showing his percentage of sales, which is based upon the dollars' worth of sales made in proportion to the population and selling expense. Every four months the leading district managers, branch-house managers, block men and dealers, and, in fact, every one who helps to make up the success of the organization receive prizes as an appreciation of their efforts. The whole organization can be likened to a gigantic spider's web. The United States is the web and so carefully supervised that the smallest report comes to the office with telegraphic rapidity.

TIRE INFLATORS SAVE MUCH HARD WORK.

By having some form of compressed gas or means of compressing it, automobilists can save themselvess a great deal of hard labor and, what is of fully as much value, considerable time. The tire-makers are all advocating high-tire pressures, and to produce these with the ordinary hand pump is a back-breaking and time-consuming task.

So, with the advocation of increased inflation, there have been a number of devices brought out for producing gas under pressure. These vary all the way from the air or carbonic acid gas bottle, which simply stores the compressed gas, to the various mechanical air pumps. Considerable attention has, of late, been given to the problem of utilizing the waste pressure of the exhaust. This pressure may vary from 40 pounds per square inch upward, and by providing proper storage tanks and connecting pipes with valves to regulate the flow to and from the tank what was previously a waste can be made to do useful work.

The latest contrivance utilizes not the exhaust, but the compression pressure. Moreover, this is cooled so that it enters the tire cold and gives a true, not a fictitious reading on the gage. As shown in the illustration, it is very simple, consisting of an attachment to the cylinder, cooling coil and a petcock on the dashboard. To inflate a tire the petcock is turned on. This permits the compressed gas to flow through the pipe, a hose attached to the dashboard end of the latter being fastened to the



Maxim Tire Inflation Apparatus Is Very Simple.

tire. Then as the engine rotates the gas is compressed, passes through the small pipe, the coil surrounding this cools it, and from the petcock on the dash, by means of a flexible hose, it is led to the tire, to be inflated.

The very apparent simplicity of the apparatus and its operation will appeal with peculiar force to the non-technical, non-mechanical driver. The small plain petcock cannot be objected to by the most radical advocates of a clean dash. Nor could the carrying of a ten-foot length of flexible hose be classed as a hardship. The engine is running idle at the time, so that the power loss, if any, is not of moment. The attachment of the whole outfit to a car is such that any man with the ability to use a screw driver or a wrench can put it on. Taken as a whole, this device seems to be one that will fill a long-felt want.

A strong detachment of the Airship Battalion, with Captain Von Jena in command, is at Fricdrichshafen for a several months' instruction course with *Zeppelin I*, the airship owned by the German Government. The sixty men and officers will make no less than thirty-two trial ascents, which are to be completed the first of May, the weather being propitious.

Between Philadelphia and Washington

WHEN an automobile lands in a ditch, with its flywheel in such intimate contact with the ground that the motor cannot be cranked over, and when, for miles at a time, the same car has to buck deep snowdrifts, climb fallen telegraph poles, or break through fallen telegraph wires, it may be considered as having a pretty extreme test. And if, when it finally reaches city streets, its motor runs as sweetly as ever, and the car glides along as if it had never tackled a Midwinter blizzard, it is a machine that is worthy of the admiration given it. This is not the tale of a run in Alaska or on the Siberian steppes, but the experience of "Jim" W. Florida and a party which tried to tour from Washington to Baltimore, a distance of about 45 miles, three days after the inauguration, in a 30-horse-power shaft-driven Locomobile.

This car was the only one which was able to get between the two cities, although several tried, and its experiences, as related by Mr. Florida, are not those generally undergone in this part of the country. In describing the trip, he says: "We provided ourselves with shovels, axes, extra sets of Weed tire chains, starting off at ten o'clock Sunday morning, and for about three miles the roads were fair, until we reached the road to Ashton, and then for two miles we had to open a way through snow waist deep. Soon we saw a driveway into a ploughed field, which farmers had been using as a road for about two miles, because the snow on the latter was up to our shoulders. To get into the field we had to jump a ditch about two feet wide.

"Our first attempt was a failure, for our rear wheels fell in up to the hubs, and the fly-wheel was tight upon the ground, but we took a dozen fence rails, raised the car and built a road under it, to get it over the embankment and into the field. We started on low gear, and when about half way from the road the car fell into a big hole, again laying upon the fly-wheel, so that we had to start road building again. In two hours we had gained two lengths, and we decided to return to the roadway and we were able to jump the ditch, but were buried right away in the snow. For a mile and a half we had to shovel snow, and then we had a chance to travel for a short distance, until we were up against another choice, of either shoveling as far as we could see, or of taking to a field. We headed for the latter, first clearing away about 50 yards of snow, tearing down some wire fence and chopping through a telegraph pole.

"Another mile, and then more miserable roads, where the telegraph poles were hidden by the snow, one of which we struck so hard that we thought that the engine had been torn loose from the frame, but an examination showed that no damage had been done. We had to chop through a great many, so that by 4 P. M. we had gone only 19 miles and it was getting dark. Just about that time we struck another long, endless stretch of tightly packed, waist-deep snow, with the alternative of climbing five feet up into a field, so down came the fences, and a kind of stairway was built. The incline was so steep that the rear wheels just threw the rails out behind them, and it was a case of rushing, after six ineffectual attempts at climbing, for the rails were out of sight in the mud. We found another entrance, and finally worked around the field, lighted our lamps, and started through more snow. We spent three hours in a nice, soft field of mud, shoveled snow for two and a half miles further, and then found a hospitable farmer with whom to spend the night.

"We stayed at the farmhouse over night and started early. The going was very slow. We shoveled for practically two miles, into Clarksville, taking us two hours, but from that point to Baltimore we had 24 miles of fairly open roads, and this distance we covered in fifty minutes, showing that the car was not injured by its strenuous experience. It was a delight to finally reach the streets of Baltimore, and the motor hummed along as if nothing had happened, and the driving mechanism did not show, in the least, the terrific strain which it had undergone. We were given quite a reception in Baltimore, for it was known that we were trying to get through, and four other cars had failed."

Subsequently Florida renewed his journey homeward to Philadelphia, conquering added rough roads, but more easily because of the absence of snow and the unusual conditions attending the Washington-Baltimore section.

Something About the Herreshoff

A STUDY of the new Herreshoff brings the conclusion that in this work of producing a car with carefully interrelating parts, the cost has been made subservient to the main functions of utility and ability. This being the case, the result is a product which displays the maximum total efficiency. The motor is of the four-cylinder vertical type, with the cylinders cast in pairs. With this form, too, the three-bearing crankshaft is used. Here again is a deference to the popular prejudice against the use of two bearings, one at each end of the shaft. To the lay mind this presents opportunities for trouble, without any offsetting advantages.

Absolutely Straight Line Drive.—The motor is placed very low in a sub-frame in order to get an absolutely straight line drive to the rear axle. This is based on the reasoning that if a small angle reduces the friction losses in the use of universal joints, an absence of any angle whatever must reduce these losses still further, possibly to zero. Inlet and exhaust valves are on one side, mechanically operated by a single cam-shaft. The valves are interchangeable, 1 5-8 inches in diameter, and the valve springs are very large. The push rods, which lift the valves, are fitted with spiral springs which deaden the impact of the push rod meeting the valve stem. An absolutely automatic carbureter is employed and gives a range of speed of the car from 7 to 45 miles an hour with five passengers. Range of mileage on one gallon of gasoline is between 15 and 18 miles, depending upon the nature of the country over which the car is driven, and the quality of the fuel.

The lubrication of the motor is by self-contained continuous oil-feed, the crank-case having a reservoir below which holds the surplus oil. An oil pump operated by worm gear sends the oil through a sight feed on the dash-board, oil running back from the sight feed to the crankcase proper, from whence it is splashed up throughout the motor. The crankshaft is fitted with three F. & S. ball bearings.

Cooling is thermo-syphon system, without water-pump or fan, thus insuring a constant temperature in the motor. The radiator is of the vertical tube type fitted with horizontal fins, and is made larger than is necessary to cool the motor, in order that the hood lines will conform with the lines of the body, which are convex.

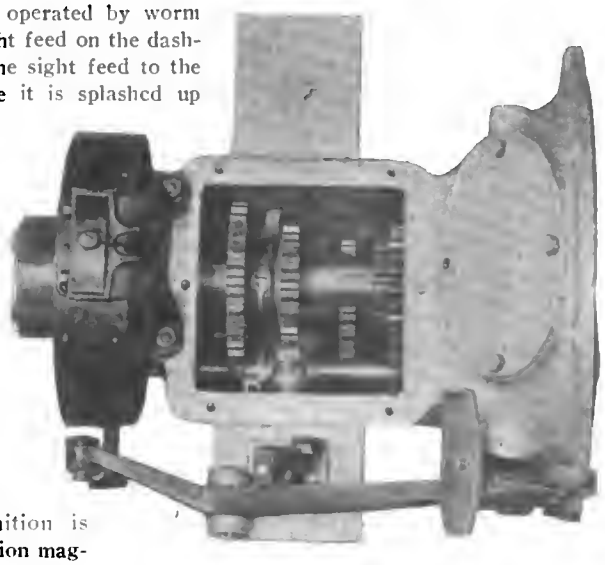
Bosch Magneto Will Supply the Sparks.—Double ignition is supplied from a Bosch high-tension magneto and a storage battery with coil and commutator, each with a separate spark plug, making the ignition separate and distinct, one from the other. Control is by switch, placed on the coil box on the dash and has three points—one for the magneto, one for the neutral point and the third for the battery. The coil is of the four unit type.

Engine and transmission are constructed in one unit, the transmission case being bolted to the case which encloses the fly-wheel and clutch. The motor pan extends under the motor and is fastened in place by four clips, such as are used on racing cars being very quickly operated.

The clutch is composed of 25 discs, which are of steel saw-blade material: entire clutch running in a bath of oil and kerosene—one pint of each. The clutch casing is fitted with a cover bolted in place with four studs.

Transmission gears, three forward and one reverse, are on the same lever—progressive type—thus insuring compactness and eliminating chance of disarrangement. The gears are projectile steel, accurately cut and very stubby. Located back of the transmission is the foot brake, lined with Thermoid, the very latest brake lining material which is almost indestructible. Between the motor and the transmission there is one joint and between the transmission and the front part of the drive-shaft there is a very large ball-and-socket joint, containing another square joint, which gives an absolute universal movement and takes up all undue strains from the motor.

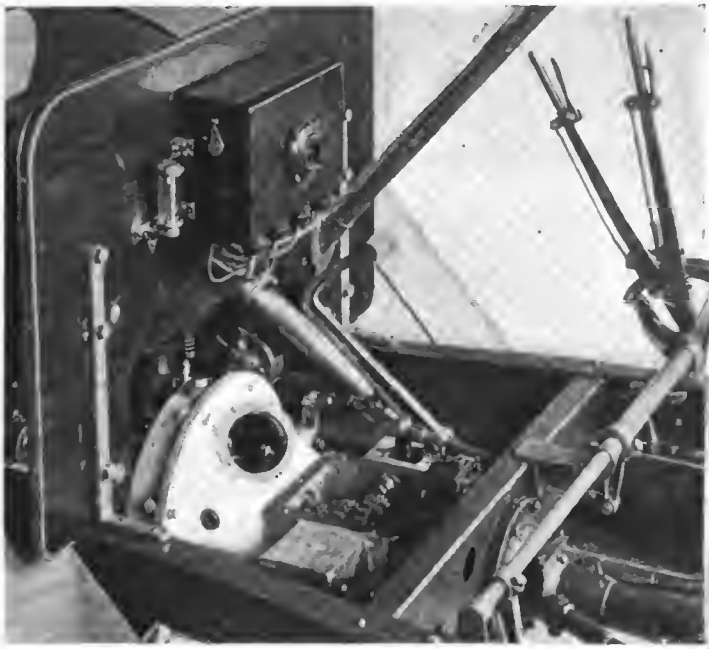
The frame of the car is narrowed at a point just back of the dash board, in order to insure close turning, and is widened on the top and deepened at the point where it is narrowed. There is also fitted a cross member, because the frame gets its greatest strain at this point. The motor and transmission unit is hung in a sub-frame, which is connected with a side frame by pressed steel plates, thus taking any strain from the motor and transmission, which might come from one side of the frame being higher than the other. Drive to the rear axle from the transmission is by tubular shaft, thus insuring lightness and great strength, and fitted with ball thrust bearings. Control of the motor is by throttle on top of the steering wheel, which is 16 inches in diameter, and by foot accelerator, both working directly on the carbureter. The point of ignition when running on the magneto is fixed to suit all speeds of the motor, while in the battery ignition the commutator is advanced by spark lever on top of the steering wheel. The former makes for simplicity while the latter is a necessity.



Top View Shows the Few Gears Used.

Ball and Roller Bearings Are in Profusion.—Both front and rear axles are by Timken and are fitted with roller bearings. The front one is of high carbon steel of the well-known Timken alloy heat treated, and is drop-forged in one piece. Steering arm is placed over the front axle and the coupling rod is back of the axle. Nine and three-quarter inches road clearance is permitted by the front axle. Rear axle is semi-floating, the live axles being secured where they fit into the differential case and tapered and keyed into the hub. The rear part of the case over the differential is removable and held in place by four bolts, thus allowing the differential to be taken out on the road after the live axles have been removed.

Provisions for keeping the driving strain of the motor away from the springs are composed of two tie-rods running diagonally from the extreme ends of the rear axle to the front end of the torsion tube, and combined with the torsion tube, which encloses the driving shaft, braces the rear axle at either end and also in the middle—the springs doing the work which they are designed to do, that is, to give an even rise and fall of the body on rough roads, without lifting the rear wheels from the road.



Note the Clean Dash, Nothing But the Coil.

Half-elliptic springs of the flat type are shackled on the front end as well as on the rear. Wheels are second growth hickory, 32 inches in diameter, with 12 spokes in the rear and 10 in front. The car has 100-inch wheelbase, the rear cushion of the body is 48 inches in length, 18½ inches depth and 6½ inches high. Foot room in the tonneau is 27½ inches, as against 25 inches in other cars at the same price, and the rear cushion is one inch longer than in other cars of the same price and of equal wheelbase.

Springs are of the same quality steel as is used in cars at three times the price. They are not bored in the center and fastened with a bolt, but are pressed out in the center, so that the projection of one leaf fits into the depression of the leaf below it. The springs seats are so shaped that the springs cannot shift. F. & S. ball bearings are used throughout the car with the exception of the axles.

Simple Control Attracts the Novice.—One pedal operates the clutch and brake on the transmission, thus eliminating any chance of a novice applying the foot brake, without having disengaged the clutch. Gasoline feed in the touring car ins by gravity; in the runabout, forced feed, using the one-way valve of the well-known Mercedes type in the runabout. Each car is equipped with a muffler cut-out, operated by a pedal placed convenient to the heel of the right foot. Front floor boards are beveled where they fit together and are fitted with brass, thus eliminating any chance of the floor boards swelling.

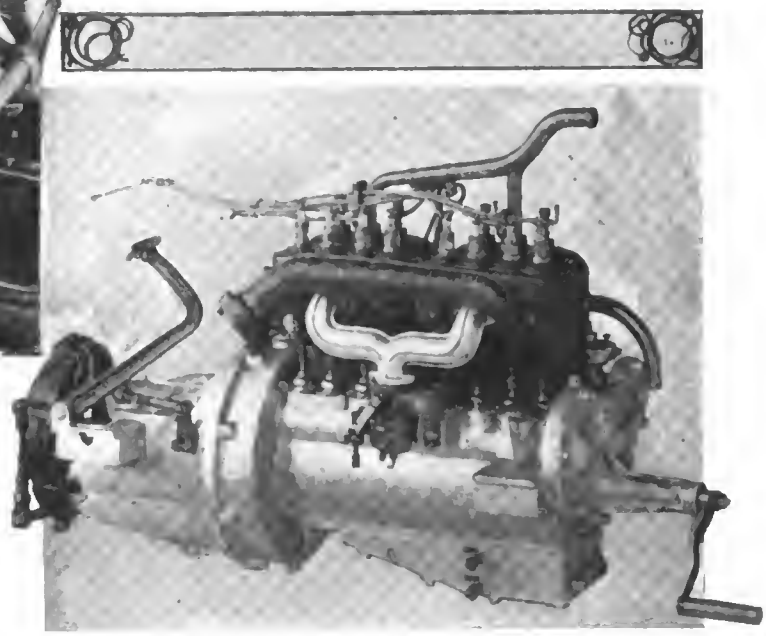
The emergency brakes are one on each rear wheel, internally expanding—shoes lined with Thermoid and are actuated by the emergency brake lever. Brake rods from the emergency lever to the brakes have two points of adjustment, which can be taken up before it is necessary to reline the brakes.

The Herreshoff is built at Detroit, but the sales have been taken over in their entirety by Harry S. Houpt, of New York City. It is understood that the output is practically sold.

CONGRESS REGULATES TAXICAB CHARGES.

WASHINGTON, D. C., March 22.—Acting under authority given by the District appropriation passed by Congress during the last session, District Commissioner West will have a conference this week with the managers of the several taxicab companies regarding taxicab rates. The section regarding taxicab rates provides, in part, as follows:

"That the Commissioners of the District of Columbia be authorized and directed to put in immediate operation, subject to change from time to time, a reasonable scale of charges by cabs, taxicabs and public vehicles for the transportation of passengers in the District of Columbia, and the tariffs so prepared shall be the maximum charges in the District of Columbia."

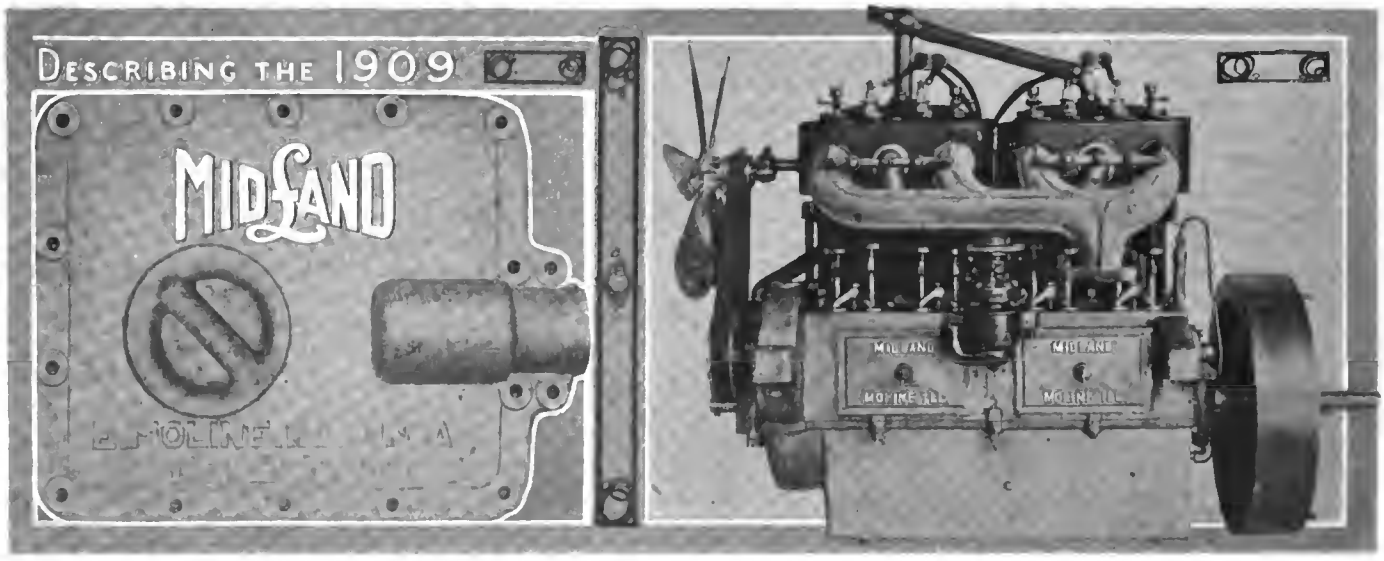


The Valve Side of the Motor Looks Neat.

It is understood that the taxicab companies are going to "stand pat" on their present rates, while the Commissioners are said to favor lower rates, so it is likely that a tug of war will ensue. The Commissioners have prohibited the use of any inaccurate taximeter, and provided for the test of meters in use by the police. The enforcement of this regulation will be taken up at once, the hack inspector being official tester.

CHAUFFEURS WANT EXAMINATION.

PHILADELPHIA, March 22.—The Professional Chauffeurs' Club of Philadelphia is actively canvassing local motordom in an effort to boost a bill, which is to be introduced into the Legislature by Representative Marvin, of Pike County, requiring every professional chauffeur to pass a rigid examination before being licensed to drive a car. The local chauffeurs ascribe the bulk of the recent deplorable accidents to imcompetent chauffeurs.



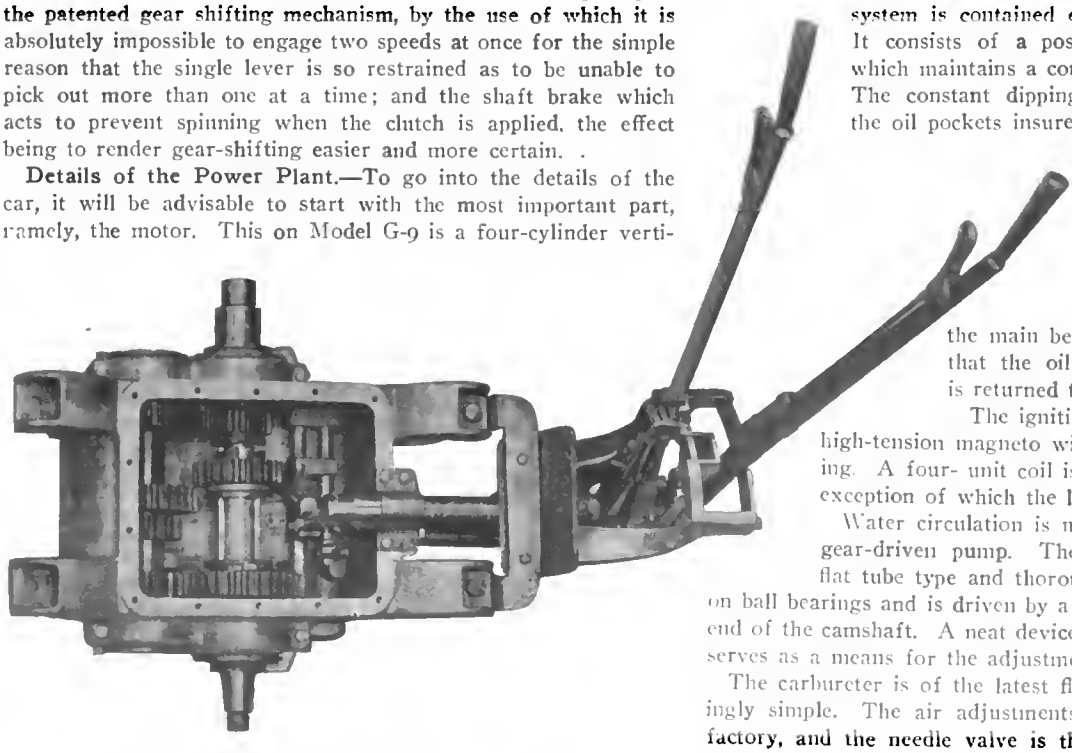
MOLINE Ill., March 22.—The sterling mark used by the Midland people in place of the letter "L" in the name, is accepted as indicative of the quality of the product, which is essentially of sterling worth. The company has decided to concentrate its energy on two models. Model G-9, which will be described, and Model E, a 30-horsepower car of the same general style, but smaller in every way and intended to sell for a lower price. This will be $1,800, while the larger model retails at $2,250, thus covering the whole range of the medium-priced medium-powered class.

As might be expected of a car thus heralded, the features which stand out and make the ensemble different from others which might resemble it externally are numerous. These, as the prospective purchaser might be glad to know, are of a mechanical nature, and such as the most advanced practice would stamp approval upon. Among the excellent features may be mentioned the offset crankshaft, which in combination with the long stroke gives superior power results with longer life; the three disc cork insert clutch, which makes for easy gradual action and positive engagement; the torsion shock absorber inserted in the driving shaft to absorb the jerks and irregularities of the driving torque; the patented gear shifting mechanism, by the use of which it is absolutely impossible to engage two speeds at once for the simple reason that the single lever is so restrained as to be unable to pick out more than one at a time; and the shaft brake which acts to prevent spinning when the clutch is applied, the effect being to render gear-shifting easier and more certain.

Details of the Power Plant.—To go into the details of the car, it will be advisable to start with the most important part, namely, the motor. This on Model G-9 is a four-cylinder vertical, water-cooled motor, with 4½-in. bore and 5¼-in. stroke. The cylinders are mounted with three-quarters of an inch off-set toward the side of the power stroke. This system of mounting cylinders greatly reduces angularity of thrust, and delivers the full power stroke to the crank with the least possible loss. It means smooth, even running of the motor, and the maximum of power at slow motor speeds. Cylinders are cast in pairs with valves on one side. The water jacket is liberal and is so arranged that the cooling water entirely surrounds the valves. These operate through push rods with rollers at the lower end. The upper ends of these push rods are made adjustable. Each piston is carefully fitted by grinding to size, and carries four rings which insure a tight compression and, therefore, the full force of every explosion.

The crankcase is of aluminum and in two pieces. The upper part carries the crankshaft bearings. These are made of the best nickel babbit and are all split bearings so as to be readily adjustable. The bearings in the connecting rods are also of nickel babbitt and adjustable. The lower part of the case is divided by partitions into four oil pockets.

Good Lubrication Is an Essential Point.—The lubricating system is contained entirely within the crankcase. It consists of a positively driven plunger pump which maintains a constant level in the oil pockets. The constant dipping of the connecting rods in the oil pockets insures a continuous bath of oil to all interior parts. The pistons are provided with the usual oil grooves for lubricating the walls, and small pockets on the main bearing supports are provided to collect oil and convey it to the main bearings, which are grooved so that the oil after passing through them is returned to the crankcase.



View from Above of Gears and Shifting Levers.

The ignition system consists of a Remy high-tension magneto with dry cells for use in starting. A four- unit coil is placed on the dash, with the exception of which the latter is clean.

Water circulation is made positive by the use of a gear-driven pump. The radiator is of the vertical flat tube type and thoroughly efficient. The fan runs on ball bearings and is driven by a flat belt from a pulley on the end of the camshaft. A neat device in the nature of an eccentric serves as a means for the adjustment of the belt.

The carbureter is of the latest float feed type, and is exceedingly simple. The air adjustments are permanently set at the factory, and the needle valve is the only adjustment necessary on the carbureter, for immediate use.

Perfectly Smooth Clutch Action.—From the motor, the power is transmitted through the clutch and a spring shock absorbed to the three-speed selective transmission. The clutch is of the three-disc type, the central or bronze plate carrying the cork inserts. A coil spring of easy external adjustment is utilized to press the steel discs into engagement. The usual ball thrust bearing is provided. Between the clutch and the transmission, acting as a universal joint, is a torsion shock absorber. It consists of two yokes attached respectively to the rear end of the clutch sleeve, and to the front end of the transmission driving shaft, and having coil springs between the outer ends. This arrangement acts as a cushion in the driving system and materially lessens the shocks, not only on the transmission and driving gears but on the tires as well.

Believing strongly in the use of good material, the Midland company have made the transmission gears out of the best of nickel steel accurately cut and carefully hardened. The nickel steel shafts are mounted on Timken roller bearings. The outer ends of these bearings are protected by dust-proof and oil-tight stuffing boxes which prevent the grease from working out and dirt from getting in. Roller bearings are used where part of the main drive shaft telescopes into the other part, thus reducing friction to a minimum and preventing sticking at this import part. The shafting fingers are contained within the casc and there are are no rods which slide through the sides of the case. The cover is the entire size of the gear box, so that when it is removed, the gears are thoroughly accessible. In fact, this question of accessibility has been carefully considered throughout the car. The gears are shifted by means of the inner hand lever which is arranged on a pivot at the lower end. When rocked inwards, the finger is picked up which operates the low and reverse. Rocked in the opposite direction, it catches the lever controlling the second and high speeds, the latter being the direct drive. The mechanism controlling this selective feature in the quadrant is distinctively Midland design, the strong feature being that the action is absolutely positive. With the hand lever thrown to one side, in order to engage one pair of gear combinations, the small lever which locks the finger for the other two combinations is positively forced into locked position without the use of springs of any sort. It will be readily seen that a positive action in this particular place makes it absolutely impossible to get two combinations of gears into mesh at the same time.

Roller Bearing Axles Well Proportioned.—The front axle is a one-piece drop-forging of liberal I-beam section and is mounted on roller bearings. The rear axle of the full floating type is of heavy gage drawn steel tubing with the differential housing in a separate piece to allow of ready removal.

Thte brakes are of both internal and external types and both are lined with thermoid lining. They may be applied in either direction, the external being applied by the hand lever, while the foot pedal operates the other. Both braking systems are equalized, as the chassis view shows.

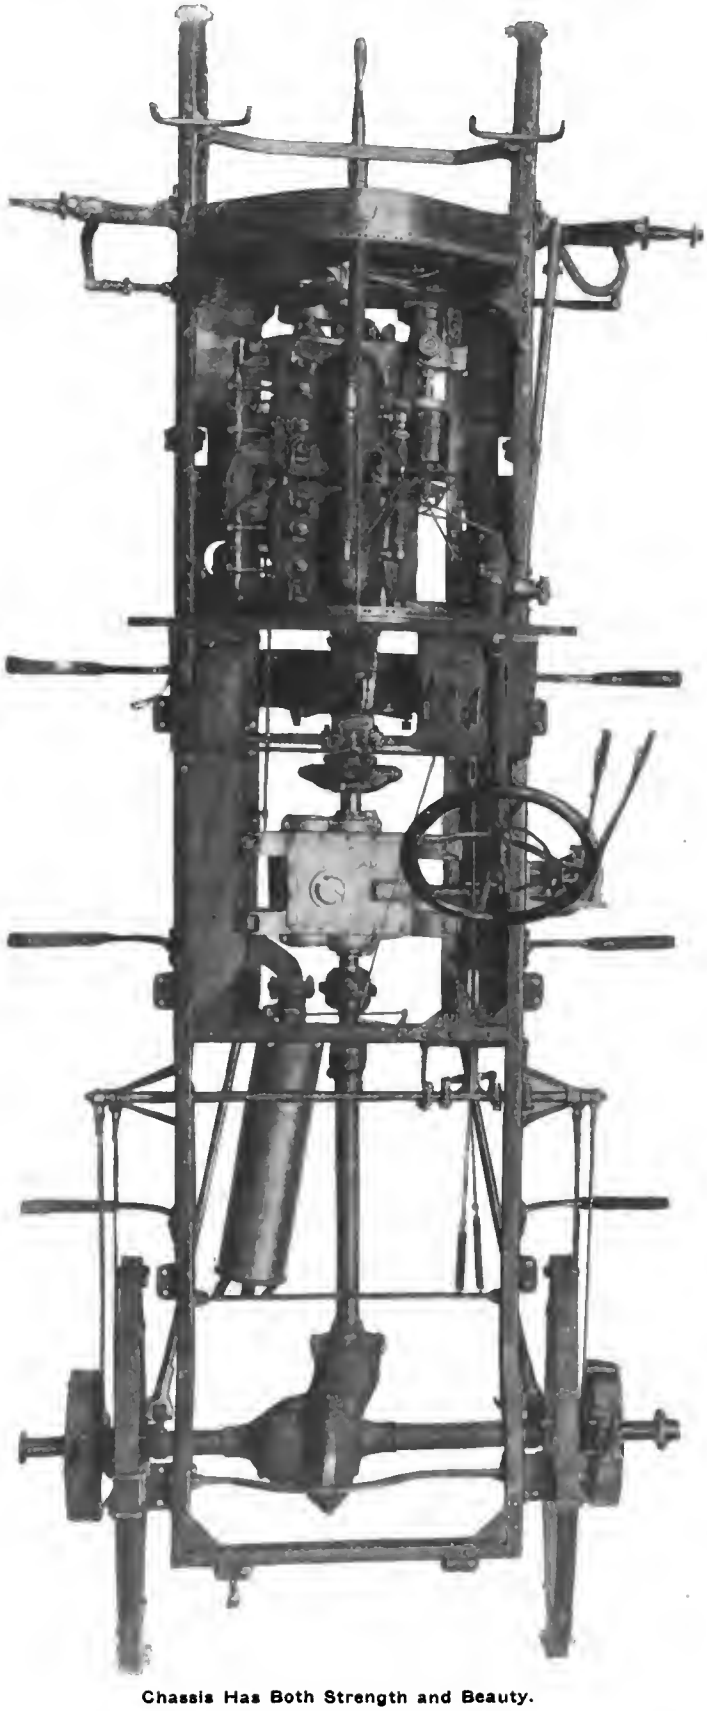
Full-sized artillery wheels are used with the number of spokes proportioned to the work to be done. Convenience on the road is affected by using the same size of tires all round, 36 by 4. Wide open springs are fitted throughout, semi-elliptic in front and full elliptic in the rear.

Simplicity Marks the Control.—The control arrangements are very simple, two hand levers at the side, four pedals and the usual spark and throttle levers being the sum total. The pedals operate, in order from right to left, the service brake, the foot-throttle, muffler cut-out, clutch.

The chassis is fitted with a handsome touring body finished in Midland red, while the running gear is done in a lighter shade of the same. The tonneau, intended for three, is long and spacious for that number. Extra folding seats may be fitted to the rear part if desired.

The upholstering is of real leather, number one quality, and handsomely tufted. The seat and back cushions are made over coil springs of the highest grade of spring steel and consequently afford the maximum amount of comfort and long life as well.

The fenders are attractive in design yet protect the car and occupants perfectly. The usual space between them and the frame is absent, being covered by splasher plates. A dust pan covers the underside of the mechanism and is quickly removable.



Chassis Has Both Strength and Beauty.

All bodies are ironed for tops and the included equipment is complete with oil side and rear lamps, acetylene headlights with a generator, tool kit and extra spark plugs..

REPUBLIC TIRE'S NEW HOME IN NEW YORK.

The Republic Tire Company of New York is now thoroughly settled in its new home at 229 West Fifty-eighth street, just off Broadway, and is better able to handle its increasing business than ever. The four floors have rapidly been arranged to best accommodate the firm in its trade, both in pneumatic tires, solid and mechanical rubber goods, and in repairing. The first floor is given over to the offices of the local concern, and at the rear to the shipping room. The mechanical goods and solid tires are handled direct from the Youngstown (O.) factory, and the second floor is used by this department. A large stock room, containing over 1,500 casings, valued at $60,000, occupies most of the third floor and the fourth is used by the repair shop. Vulcanizers and machinery for caring for tires have been installed, so that nearly a complete new tire could be made right in the shop. In the basement there is space for storing mechanical goods, such as belting. There are large windows and skylights.

H. W. Pratt, as president of the New York firm, is assisted by Frank G. Hill, sales manager, and by C. R. Morceau, office manager. These men handle the bulk of the retail and wholesale trade themselves, and report that an increase is noticeable every week, although, of course, there is not the great picking up in spring business that there used to be before automobiles were used all winter long. The fact that the cars are used at all times, they say, is responsible for the steady amount of business done, and the Republic factory, at Youngstown, is working to the limit to supply the demand, not only from the metropolis, but from other cities as well.

FIRE DESTROYS MUCH IN RANDS FACTORY.

Detroit, March 22.—Damage to the extent of between $25,000 and $30,000, partly covered by insurance, was suffered by the W. C. Rands Manufacturing Company, of this city, recently, in a fire which destroyed a large amount of stock awaiting shipment. Automobile tops, cushions and accessories, made by this concern, ready for shipment, were burned. The origin of the fire is unknown, but it started in the stock room. The entire factory will be rebuilt.

Dallas, Texas.—The Dallas Mfg. Co., handling Baker electrics in that portion of the State, has recently placed a contract for a fine up-to-date garage, which will be the best equipped in Dallas.

GOODYEAR COMPANY WINS LEGAL FIGHT.

Akron, O., March 22.—A decisive victory in a long-drawn-out legal battle has been gained by the Goodyear Tire & Rubber Company, over the Consolidated Rubber Tire Company, in the denial by the Supreme Court of the United States, March 8, of the certiorari petition made to it by the Consolidated company for the second time.

The suit was begun in the spring of 1899 by the Consolidated company, and a decision adverse to the Goodyear company was appealed. In May, 1902, this was upheld by the circuit court of appeals. The Consolidated interests carried the case to the United States Supreme Court, and their petition was denied. About two years ago they obtained a favorable decision against another concern in the New York district, and opened the case with Goodyear, but for the second time their petition has been denied, so that the Goodyear company is free to sell solid tires in any part of this country, without itself or its customers being annoyed. This, however, does not affect other rubber tire manufacturers or their users, who are still assailed by the Consolidated company.

HANDSOME PIERCE TO TOUR EUROPE.

Buffalo, N. Y., March 22.—One of the hansomest automobiles ever built, and one of a type that has never before been turned out in this country, was last week delivered to George K. Birge, of this city, by the Pierce-Arrow Motor Car Company. It will be used in touring Europe during the Spring, and has already been started on its journey, to join Mr. Birge, who sailed on last Saturday.

The car has a regular six-cylinder chassis of 60 horsepower, and it is in the body equipment and finishing that the art is especially shown. The body is of the landaulet style, with lines that are similar to those of old English stage coaches, seating two, three, or four people, in addition to the chauffeur. Behind the body there is a large permanent baggage boot, which holds three trunks of various sizes, in a black leather casing. The car is painted a brilliant chrome yellow, with just enough touching of black to form a pleasing contrast, and the interior is upholstered in hand-tooled leather, of a golden russet hue. The driver is well protected by a glass front set back several inches from the dash and a separate victoria top so shaped as to conform to the body lines. Many conveniences, not ordinarily provided, have found places in this admirable outfit.

Pierce Great-Arrow with Old English Stage Coach Body, to Be Used on Continental Roads by George K. Birge, Buffalo, N. Y.

News in General

Rambler Touring Car Converted Into a Garden Produce Truck.

J. Q. Adams, of Eagle Rock, Cal., has changed his 40-horsepower Rambler touring car into a truck capable of carrying nearly a ton of garden produce, the load formerly needing three wagons, at a much faster rate of speed.

Hints on Care of Tires.—"It is not sufficient that a careful driver should examine his car to see that the tires are not underinflated, and provides against overloading and remedies any defect in the rims; there are other things to be considered if one wishes the tires to last long," says G. M. Stadelman, of the Goodyear Tire Company. "The dashing driver who starts with a jump, throws on the high gear within a short distance and then drives almost to the desired point, stops, then slams on the brakes, will find that his tires will not last long. To put on a high rate of speed suddenly on a slippery pavement, or a sandy road, so that the wheels fly around, while the car is barely moving, is not conducive to long life of the tires. The man who runs his machine in the ruts along a country road, so that the sides of the tires scrape against the side of the ruts, and the man who bumps the sides of his tires against the curbing of the pavements will find that his tires die a sudden death."

Whitney Mfg. Co.'s Benefit Assn.—The annual meeting of the Whitney Manufacturing Company Mutual Benefit Association was held recently in the factory smoking room, Hartford, Conn., and officers for the coming year elected. They are as follows: President, Warren J. Belcher; vice-president, John J. Smith; secretary, Arthur L. Brown; treasurer, J. H. Triesbach; trustees, C. A. Pease, Chas. Johnson and R. J. Grady. The reports submitted showed a cash balance of $500, and it was voted to admit the women workers in the shops, the present membership being limited to men, and 97 of these are on the roll.

Making a Big Hit in England.—There seems to be evidence at hand to prove that American automobile products are gaining a strong foothold abroad. A recent writer on the subject of brakes and brake lining in the London *Sporting Times* said in part: "I have an old-fashioned brake system on my car which has never been satisfactory until lately, when I lined them with a new stuff called Raybestos. Oil will not burn it out or carbonize. The braking efficiency is wonderful; I believe I could pull up on a one-in-four grade without the foot-brakes. The stuff is not cheap, but this is compensated by the wearing qualities.

Wheeler & Schebler Offer Trophy.—An order for a silver trophy, to be awarded by the Indianapolis Motor Speedway, has been placed with Tiffany & Company by Wheeler & Schebler, carbureter manufacturers of Indianapolis. It will cost about $5,000, and will be 8 1-2 feet high, of dull-finished sterling silver. A figure representing Victory, holding out a laurel wreath, standing on a winged wheel, depicts the nature of the contest in which it will be won, while its international character will be shown by two other figures, one an American Indian and the other a European athlete.

More Americans for Philadelphia.—With its first allotment of 25 American cars sold, the Stoyle-Vogel Auto Company, of Philadelphia, has secured ten additional cars from the factory, making a total of 35, which, as Mr. Vogel says, "Is going some for a comparatively unknown product in old Phillie." The company has found its new show room, at the corner of Broad and Race streets, a success, using its former location on Spring street for storage and supplies.

Half of Winton Output Delivered.—More than half the season's output of Winton Sixes has already been delivered to purchasers, and of the remainder but few are available for sale. The Winton Company does not regard agents' blanket orders as sales, otherwise the announcement could be made that the output has already been oversold.

Ex-Secretary Newberry to Tour Europe.—T. H. Newberry, who was the Secretary of the Navy with ex-President Roosevelt, will sail for Europe on March 31, taking with him a Packard car. With his wife and daughter he will tour through France, Germany and Italy, spending months in these countries.

'Twas a 20-30 Renault Runabout.—Paul Lacroix, the general manager of Renault Frères Selling Branch, Inc., states that the car which he used in the run from New York to Boston was a 20-30-horsepower runabout and not one of 35-45-horsepower, as published.

Oakland Chassis Used for Instruction.—At the Rock Hill College, Ellicott City, Md., a chassis of an Oakland car is being used as a model for instruction in a mechanical drawing class.

BECKERS CHANGE POSITIONS.

CLYDE, O., March 22.—A change has been made in the management of the Elmore Manufacturing Company of this city, whereby B. A. Becker and J. H. Becker exchange the positions which they have been holding up to the present time. By a new arrangement the former becomes secretary and general manager and the latter treasurer. This is a change to duties more congenial to each and in no way will it alter the policy of the concern. The management of the entire factory, offices and sales departments will continue in the hands of these two men.

TAXICABS AND TRANSIT.

Atlanta, Ga.—This city now has a taxicab service, eight machines having been installed recently by the Atlanta Taxicab Company. This number, however, represents only the beginning, intended to show the people what the cab can do. More machines will be added later.

Los Angeles, Cal.—A new taxicab service has been started in this city, known as the Red Line. The Western Motor Car Company, responsible for this move, have put into service twenty Chalmers-Detroit taxicabs.

Menardsville, Tex.—An automobile line has been established between this town and Brady by Decker & Benchoff. A 30-horsepower Cadillac will make a round trip every day.

BUSINESS CHANGES.

W. J. Kells Manufacturing Company, New York.—The W. J. Kells Manufacturing Company, makers of the Kells honeycomb water coolers, has moved from its location in Jersey City to 726 and 728 Eleventh avenue, New York City, near Fifty-second street. Its facilities have thus been much improved and enlarged and in addition to making radiators and coolers it will also produce other automobile supplies, such as mufflers, hoods, mud guards, tanks, etc. An especially equipped repair department has been opened.

Bruns Automobile Company, Brooklyn, N. Y.—The Bruns Automobile Company, the agent for the Chalmers-Detroit, has moved from its quarters at 31 Grant square to its new salesrooms and offices at 1295 Bedford avenue. The old location will be used solely for garage purposes.

Midland Motor Car Company, Kansas City, Mo.—The Midland Motor Car Company, the Kansas City agent for the Peerless and Oldsmobile cars, has moved into its new quarters at 1606 Grand avenue. Spacious salesrooms and offices and increased garage facilities are thus secured.

Where Ajax Holds Forth in Boston.

IN AND ABOUT THE AGENCIES.

Thomas, New York.—Thomas cars will be sold in New York City hereafter by a branch of the E. R. Thomas Motor Company, under the management of W. B. Hurlburt and C. R. Teaboldt. This has been arranged through a mutually satisfactory agreement between the Thomas company and the Harry S. Houpt company, the latter having had the agency for these cars for several years. The branch management has already taken charge of the selling end of the business at Broadway and Sixty-third street, but the garage business will be continued by the Houpt company until April 1. The branch will be organized as the E. R. Thomas Motor Company of New York, and will carry on a business not only in the selling of automobiles, but also in supplying parts, and a fully equipped repair shop and garage will be conducted.

Crawford, Philadelphia.—The Thomas M. Twining Company, 326 North Broad street, has given up the Philadelphia agency for the Crawford, and will hereafter devote all its energies to popularizing the Regal in the Quaker City.

Cadillac, Aberdeen, S. D.—Northwestern Cadillac Company, formed by L. E. Horton, of Minneapolis, and Porter J. McCumber, of Wahpeton, N. D., to operate in States of North and South Dakota and Minnesota.

Crawford, Kansas City, Mo.—The Ettwein Motor Car Company, 3701 Main street, has been appointed agent in this city for the Crawford car.

Premier and Reo, Chattanooga, Tenn.—Tennessee Automobile Company. H. Blacklock, president; R. A. Brantley, secretary and general manager.

Marmon, Chicago.—Adams Automobile Company, formerly agent for the Austin, 1420 Michigan avenue.

Smith, Kansas City.—The Hollister Motor Car Company have taken the agency for the Smith car, made in Topeka, Kan., by the Smith Motor Car Company.

KisselKar, Kansas City, Mo.—KisselKar Company, 1122 East Fifteenth street, C. A. Post, manager.

Ford, San Antonio, Tex.—Ford Automobile Agency, 124 Avenue D, for southwestern Texas.

Marion and Midland, Boston.—New England Sales Company, B. F. Blaney, manager.

Studebaker, Boise, Idaho.—Studebaker Bros. Vehicle Company, factory branch.

Lozier, Portland, Ore.—H. L. Keats Company, distributers for the State.

Chalmers-Detroit, Gloversville, N. Y.—J. A. Schmidt, for Fulton County.

Moon, Tulsa, Okla.—Wallace Automobile Company.

Mocn, Louisville, Ky.—Kennedy Automobile Company.

PERSONAL TRADE MENTION.

Monte Cross, Autoist.—That the management of a baseball team, the covering of shortstop and automobiling make a good combination is averred by Monte Cross, the manager and shortstop of the Kansas City team of the American Association. After spending the winter in the Philadelphia branch of the Winton Motor Carriage Company, working in the shops, he has become a full-fledged automobilist and has just completed a trip from Pittsburg to Kansas City, Mo., with S. T. St. Clair, of the former city, in Mr. St. Clair's Winton touring car. A fast run was made in order to see the Kansas City show before its close, and also to start preparations for spring baseball practice, and not a bit of trouble was experienced, although Monte feels sure that he can repair anything that may happen to a car. He expects to sell automobiles when not playing baseball.

F. R. Bump, sales manager of the H. H. Franklin Manufacturing Company, is making a five weeks' trip through the Rocky Mountain States and along the Pacific slope, visiting Los Angeles, San Diego, San Francisco, Portland, Vancouver, Victoria, Spokane, Walla Walla, Pendleton, Boise, Salt Lake City, Colorado Springs and Denver, with stops at Omaha, St. Louis and Chicago.

George W. Squires, long identified with the automobile trade in Indianapolis, has accepted a position as city sales manager of the Finch & Freeman Auto Company, the agent for the Haynes, Richmond and Auburn cars.

William T. Skeggs, formerly with the Chicago Buick branch, has joined the sales force of the Centaur Motor Company, the agent in Chicago for the Oakland and Moon cars.

Frank G. Lowry, until recently advertising and publicity manager of the Moline Automobile Company, has now returned to his former occupation as automobile editor of the Indianapolis *Star*.

Alexander Winton, president of the Winton Motor Carriage Company, and Mrs. Winton are expected home from Scotland about March 27.

C. B. Smyth has become superintendent of the McKeen Motor Car Company of Omaha, Neb. He was formerly with the Union Pacific.

RECENT INCORPORATIONS.

Wonder Manufacturing Company, Syracuse, N. Y.—Capital, $40,000. To manufacture motor boats and automobiles. Incorporators: W. D. Boyle, G. T. Hurd, Bertha C. Cornwell.

Bi-Cal-Ky Auxiliary Spring Company, Buffalo.—Capital, $100,000. To manufacture auxiliary springs for automobiles. Incorporators: C. H. Bicalky, C. H. Lockwood, F. J. Bommer.

Dow Rim Company, New York.—Capital, $100,000, to manufacture vehicles, motor cycles and bicycles. Incorporators: F. J. Erwin, W. H. Heagerty, Emma W. Renne.

Napier Motor Company of America, Portland, Me.—Capital, $1,000,000. To manufacture and deal in engines, motors. Incorporators: H. B. Clarity, F. T. Fagan.

Fiat Automobile Company, Chicago.—Capital, $100,000, to deal in automobile supplies. New York corporation.

NEW TRADE PUBLICATIONS.

Firestone Tire & Rubber Company, Akron, O.—The latest book from the Firestone press is called "Progressive Locomotion," and, as its name would indicate, is devoted to the progress in vehicle construction made from the time of the Egyptian chariot down to the modern automobile. It is handsomely illustrated with decorative panels. The second section is given over to the oft-told story of the rubber tire, which is here told in a very interesting way. The methods used in gathering the juice from the tree and in preparing it after its arrival at the tire factory are described in detail with a series of well-chosen illustrations. One most interesting fact given is that the number of acres of trees now under cultivation is so large that there is no danger of a rubber famine. This conclusion might have been reached in another way by inspecting the views of the Firestone factory as it was originally and as it is to-day.

B. F. Goodrich Company, Akron, O.—Under the attractive caption of "What Tires Have Done as Well as This?" the Goodrich people are sending out a little book of 28 six by eight pages. This, as its title would indicate, is a record of the meritorious performances of Goodrich tires in the past season, although a pretty small book to chronicle such wholesale achievements. The series of very interesting vignettes scattered through the book picture the various routes over which the contests took place, the effect produced by the use of brown outs on white with a dark gray outline being excellent and most effective. Reproductions of letters and telegrams give a matter-of-fact appearance which is very convincing.

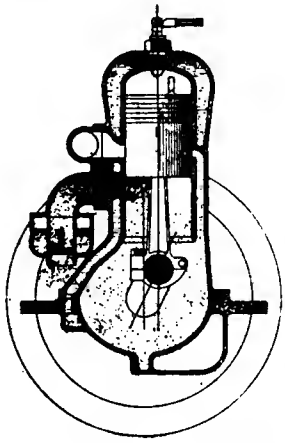
Diamond Rubber Company, Akron, O.—The opening sentence of the new motor truck tire catalogue is descriptive of the whole book. This says "getting right down to the ungilded facts . . . ." Then follows a short, terse statement of the desirable qualities in motor truck tires, followed by an equally short and to the point statement of the good qualities of the wire mesh base tires. Sizes are given together with a description of the tire applying machine. A chapter on the proper care of tires and the various codes used complete the 32 pages of this 5 by 7 book.

Winton Motor Carriage Company.—"Price vs. Value," a book just issued by the Winton people, presents in detail the method adopted by the manufacturer in deciding upon a selling price and presents some inside facts not previously published.

One Shipment of Forty Reos in Front of the Poppenberg Motor Car Company's Building, Buffalo, N. Y.

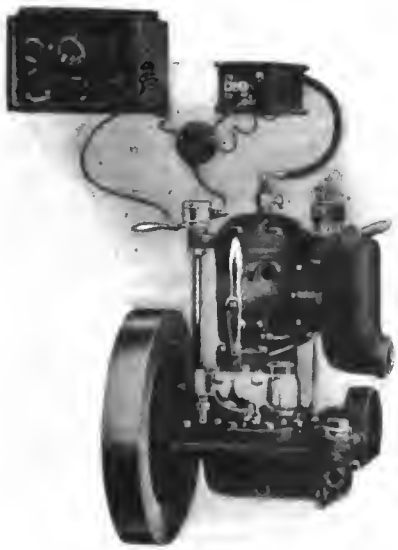
INFORMATION FOR AUTO USERS

Ferro Two-cycle Motors.—One of the "stunts" of the Ferro Machine & Foundry Company, of Cleveland, O., has been the filing of suggestions for improvements. By taking the best of these, many improvements have been produced for the 1909



SECTION FERRO TWO-CYCLE MOTOR.

motors. Among the notable changes in the new Ferro motor is its offset crankshaft. This construction provides a slight deviation in the alignment of the cylinder center with the center of the crankshaft, so as to give the connecting rod practically a vertical position on the downward or impulse stroke. The merit lies in the transmission of energy from the piston directly down upon the crankshaft, reducing the



EXTERIOR VIEW FERRO MOTOR.

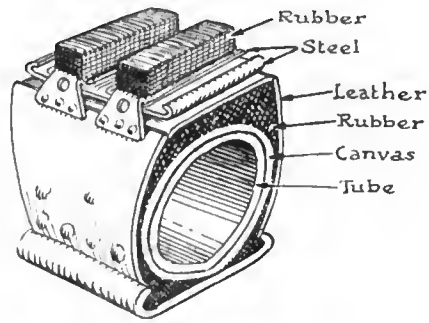
side thrust of the piston upon the cylinder wall, and, therefore, reducing the friction and wear upon these parts. It follows that greater power development is possible, which is evidenced in exhaustive tests made. Another marked improvement is the counter-balanced cranks on both single and multiple cylinder motors. This practically eliminates vibration. To withdraw the piston and connecting rod requires but the removal of the cylinder head and a plate in the crankcase. Through this hole the bearing is disengaged and the piston and rod can then be removed through the top of the cylinder, and the motor otherwise need not be disturbed from its foundation. The bearings are so constructed as to be quickly replaced or adjusted. Briefly, they consist of babbitt metal, the lower half being made in the crank base, with ample length and diameter. The upper half is a bronze cup poured with babbitt and mounted upon several brass liners. To those patrons who desire make-and-break ignition, the company is ready this season to supply it. It is an extremely simple mechanism with a control lever, which also permits of reversing the motor. It is made attachable to all Ferro motors. After a series of thorough tests upon several designs, a clutch that will stand up to the full requirements of a marine motor without being a constant source of attention and worry has been produced. The company has installed new machinery especially adapted to produce their clutch, which is constructed so as to be directly attachable to the base of the motor, making it a rigid part of the engine frame, and not possibly giving rise to any lost motion between them. The adjustment of both forward and reverse brake bands are outside, easy of access, and a ball thrust bearing upon the after end of the clutch frame removes pressure from the working parts. Another appreciable attachment is the rear chain starting device.

Nightingale Whistle.—This whistle is manipulated by a foot pedal, and has a response which, for agreeable and vigorous effectiveness, appears to be all that the autoist can desire. It is manufactured by the Nightingale Whistle Company, 1693 Broadway, New York City, which calls attention to the fact that the whistle is in wide use, with an ever-increasing clientage. The whistle is connected with the exhaust of motors between the motor and the muffler in each case, and means are provided for effectively allowing the right amount of exhaust gas to enter the whistle

THE NIGHTINGALE WHISTLE.

and serve the end. Back pressure is avoided in that the exhaust is "shunted" into the whistle, hence the excess can go to the muffler. The whistle is of a convenient size, and while a rich melody is the sound which the whistle gives in normal town work, the fact remains that the autoist can project "a mile of sound" of the kind which will awaken a sleepy farmer who goes into a trance on his way home, leaving it to his horses to find the way.

White Tire Company.—Punctures, blow-outs and skidding; the gamut is run and the man with the car punctures the atmosphere in his vehemence. But this can all be as history, according to the makers of the "White," and as the illustration here given shows, years of experimenting in this direction ended in a tire which is so well protected as



CROSS SECTION OF WHITE TIRE.

against the happenings of the road that autoists can well afford to sit up and take notice, as the saying goes. At the show room of the company at Broadway and Seventy-second street, a tire will be found on exhibition, and the genial representative of the company will be glad to explain. In the meantime it will be wise to settle down to the firm conviction that the tire is armored in a most effectual way, and the means of preventing skidding are in the fullest accord with pyramided knowledge.

Latest Warner Auto-Meter.—The latest additions to the line of products of the Warner Instrument Company, Beloit, Wis., are the models O and P, as shown in the accompanying cut. Model O is equipped with a 60-mile scale, while the other is for higher speeds and has a 100-mile scale. The speed indicator consists of the latest 1909 model with 100,000 mile total and 1,000 mile trip odometer. The clock is of the same high grade as, and is a fit companion for, the well-known Warner Auto-Meter. It is an eight-day movement with a special winding attachment, which does away with the necessity for carrying a key. The construction is such that the light from the reflectors is thrown on the dial only. It is claimed that with this method of illumination, the light is diffused evenly over the four-inch silvered dials, none being lost by outward reflection from the glass, as is the case when the light is placed outside of the instrument or clock.

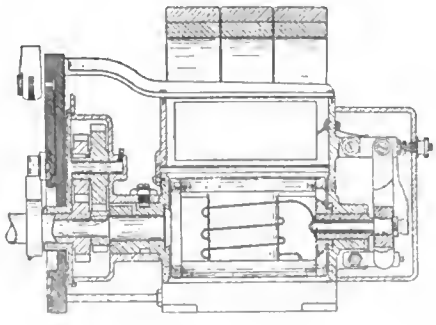
THE NEW MODEL O WARNER AUTO-METER, WITH 60-MILE SCALE.

New Models of Stewart Speedometers.—In addition to Models 4, 5, 9, 10, 11, 12 and 13, already well known to the trade, the Stewart & Clark Manufacturing Company, Chicago, has added the following speedometers to its line: Model 14, a combination of Model 11, sixty-mile multipolar instrument, mounted on a standard with an eight-day automobile watch; Model 15, a combination of Model 12, centrifugal type, and an eight-day automobile watch, the latter mounted on top of the speedometer; Model 16, a combination of Model 11, ninety-mile multipolar instrument, and an eight-day watch (this speedometer is equipped with diamond bearings); Model 17, a combination of Model 11, ninety-mile multipolar instrument, with Chelsea clock and electric light. This speedometer is also equipped with diamond bearings.

STEWART SPEEDOMETER, MODEL 14, AND SUPPORTING ARM.

The standard used with Model 14, and which is shown in the cut, is a distinct innovation. It lifts the instrument away from the dash, with the view of making it more easily seen and read. A steel core runs through the standard to the instrument, which has a bevel gear connection with the flexible shaft at the bottom of the standard. This arrangement eliminates the necessity of bends in the shaft, and it runs straight to the wheel of the car. The standard is handsomely finished in brass.

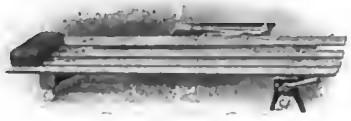
Fawn Magneto Shows Nice Detail.—Of the open-circuit type, with a shuttle-wound armature, so divided that the control is automatic, in order to afford the same voltage at low, as at high speed. The timing of the spark is to a nicety,



CROSS SECTION OF FAWN MAGNETO.

due to the use of a contact system, the further advantage of which, lies in the ability to employ, in conjunction with the magneto, any desired spark coil. For the purpose of advancing and retarding the spark a device called a timer-box is used, and incorporated into the magneto. This device consists essentially of a system of gears and a sleeve arrangement by means of which the feat is accomplished, and the details of the plan are shown in the accompanying cross-section of the magneto. This magneto is made by the Fawn River Mfg. Co., of Constantine, Mich., whose literature is most complete and instructive.

Auto Repair Truck.—The latest product of the Motor & Manufacturing Works Company, Geneva, N. Y., is designed to save the chaffeur from getting his back full of oil and grease from the dirty floors of the garage. This auto repair truck, as it is called, is provided with casters, thus allowing the operator to lie on his back on it and propel himself under the car to the place where the work is to be done or anywhere else in the room. A hand lever, which controls the back casters, may be thrown over, raising the latter from the floor and thus, anchors the outfit in the desired position. The truck is provided with a sliding shelf to carry tools and small parts. This is clamped to the side of the truck and may be removed, placed on the opposite side or in any desired position. The head rest is of real leather. The slats, which form the main part of the structure, are glued and screwed, making a strong, durable and light construction. As designed for the chauffeur or owner, adjustments and repairs may be made more quickly and more comfortably than could be done with a pit.



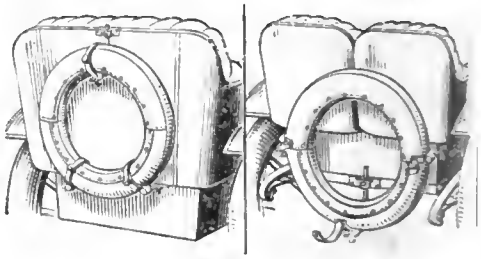
ADJUSTABLE AUTO REPAIR TRUCK.

A Low-Priced Quality Spark Plug.—It is true, there are good spark plugs, but they run into money. What the Standard Sales Company, of 1779 Broadway, New York City, is engaged in, according to J. Stewart Smith, is the production of a superior spark plug, at the price of the other kind. The shell or body of the plug is made of machine steel in all standard sizes, as A. L. A. M. and metric-pitch threads. The Fry plug is made in open and closed types to suit the different requirements, and the insulation is either mica or porcelain, at the option of the purchaser. The packing gland is of brass with a thin annular ring-like projection at its inner end which acts as an equalizing spring, allowing for the expansion of the porcelain. An absolutely gas-tight joint is assured and stability is written all over the plugs of this make.

FRY SPARK PLUG.

Ashton Acetylene Separator.—It is not a generator but it is used in connection with generators, for the purpose of rendering the gas pure and capable of delivering the best results. The separator is attached to any part of the car between the generator and the lights, but not so close to the radiator as to be influenced by the heat from the same. The separator is cylindrical in shape, 5 inches long by 1½ inches in diameter, and is provided with a bracket by means of which it can be secured into place. The principle in which the separator depends for its efficient action takes into account the property called inertia, in conjunction with the gravitational phenomena. The impurities in the crude gas, as it leaves the generator, are heavier than the gas, and they are shaken out, due to changes in direction in the separator, and the fact that the heavier compounds bombard the surfaces against which they strike. When the gas shakes off the heavy substances it is passed through a drying process and it is then fit to go to the lamps, for the purpose of delivering a steady, clear white light. The separator is to be had from W. E. Ashton and Dorr Company, 1415 Race street, Philadelphia.

Allen Tire Holding Specialties.—Several different kinds of tire holders, covers and locks have been exhibited at the shows by the Allen Auto Specialty Company, of New York, makers of these devices for overcoming a serious trouble to autoists. Extra tires are carried by all cars and how to do so without exposing them to the weather or to being taken from the cars when standing alone has been a problem. This company makes a tire cover which does away with the first nuisance in the cover, with a reversed overlap and buttons so arranged that it will fit a worn tire as well as a new one. These are made of enameled duck and are water-proof. A special type is made for Stepney spare wheels. To prevent tires from being stolen several types of locks are made for large and small sizes, that can be fitted in a running board set or fastened at the back of the car and out of the way. In order to accommodate different styles of cars a number of kinds of ordinary holders are made, without locks, though the latter may be fitted. An additional line of specialties is made for protecting steering knuckles, universal joints and gas and oil lamps. These are of leather or enameled duck.



MODELS OF ALLEN TIRE HOLDERS.

Crown Sanitary Flooring for Garages.—Sanitation, in connection with a garage is quite important but it is of small purport as compared with sanity, as it relates to the dangers which lurk in an oil-soaked wood floor. Robert A. Keasby Company, of 100 North Moore street, New York City, makers of sanitary flooring, made a study of the conditions which abound in garages and reached the conclusion that it is the height of folly to take such risks as must be present if the floor is of wood, and if oil is allowed to saturate the wood, as it is sure to do, if the wood is not protected. Crown Sanitary Flooring is fire, water and acid proof and it is widely used in garage work.

Vol. XX New York—Thursday, April 1, 1909—Chicago No. 13

THE AUTOMOBILE

STEAM SCORES IN ATLANTA'S MEET

By Percy H. Whiting

ATLANTA, Ga., March 27.—Roaring and whistling like a tea-kettle run mad, a Model K White Steamer. driven by "Bob" Lambert, hurled itself up the nine-tenths of a mile of the Stewart avenue hill this afternoon in 45 4-5 seconds, peeling 5 2-5 seconds off the best previous mark and winning the free-for-all of the Fulton County Automobile Club's third annual climb.

A Stearns Six, 1908 model, owned by Ed Inman, president of the club, and driven by A. H. Almand, which was the only other starter, was an entertaining second, covering the distance in the rattling good figures of 48 2-5 seconds, 2 4-5 better than the same driver drove a 1907 Stearns four-cylinder last year, when he won the free-for-all and put a second leg on the Atlanta *Journal's* big cup.

So impressive had been the time trials of these two cars during the two weeks' practice to the climb that they had the free-for-all to themselves. The race was run at the close of a six-event program and evening was closing in before the White got away. With Lambert at the wheel and Stupka cuddled down behind the dash, the car got away to a whirlwind start, reaching full speed in an incredibly short time and keeping or increasing it every inch of the way up the incline. Like the proverbial "lost soul," it whistled and howled, emitting much humming from its burner and most impressive snorts from the exhaust, but its speed seemed to increase even on the stiffest part of the grade and as it charged across the finish line and down the other side of the hill toward Atlanta it was clear that all records were broken.

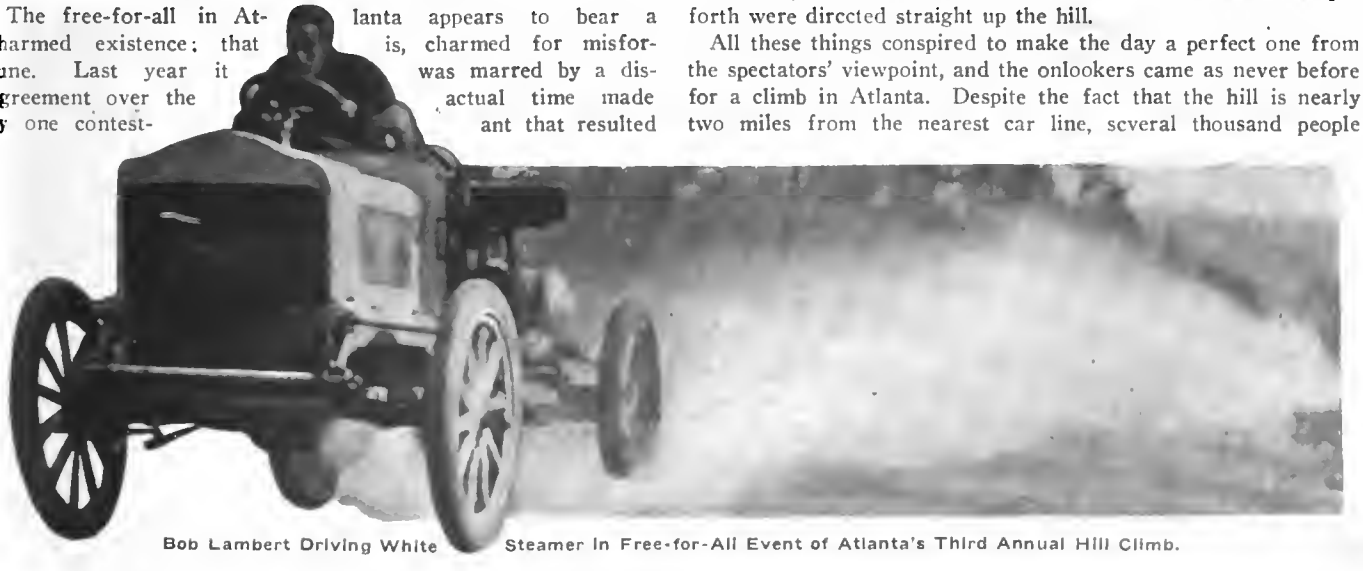
The free-for-all in Atlanta appears to bear a charmed existence; that is, charmed for misfortune. Last year it was marred by a disagreement over the actual time made by one contestant that resulted in much unpleasantness at the time, and afterwards in a row at Atlanta's most exclusive club that occasioned much scandal. This year the timing apparatus, which had stood a hard day's service without an error being charged against it, went "out of whack" after the White Steamer started. The automatic timing "jigger" received the signal that the car was off, but never one that told of its arrival. However, the many watches at the finish, which were used as a check on the official record, caught the White in :45 4-5.

Then followed much wrangling as to whether or not the White should run the race over again. Before the argument was settled the Stearns came up. It was garage gossip that Almand was exploding equal parts of gasoline, picric acid, dynamite, profanity and nitroglycerine in his motor, and certain it is that it sounded like a goodly battery of gattling guns as it popped and flew up the incline.

The official clock, back in running order again, caught the Stearns in 48 2-5 seconds. After this time was flashed there was more argument, but finally Ed Inman, owner of the Stearns, withdrew his claim on the cup, afterward qualifying this withdrawal by protesting the White on the ground that it was not a stock car. This protest subsequently was dismissed by the contest committee.

Aside from this annual "incident," the day was without mar or blemish. The weather, though not sunshiny until toward the end, was warm, and there was little wind. Such efforts as Boreas put forth were directed straight up the hill.

All these things conspired to make the day a perfect one from the spectators' viewpoint, and the onlookers came as never before for a climb in Atlanta. Despite the fact that the hill is nearly two miles from the nearest car line, several thousand people



Bob Lambert Driving White Steamer in Free-for-All Event of Atlanta's Third Annual Hill Climb.

Excellent Guarding of the Course Was One of the Marked Features of the Atlanta Hill Climb.

trudged out to the finish line, and these, with the reinforcements that came in autos and other vehicles, brought the number up to 5,000 at least. As for automobiles, verily, the woods were full of them. They lined both sides of the course, and certainly no such gathering was ever before seen in Georgia, save for the notable exception of the Savannah Grand Prize.

The officials broke all Atlanta records by getting away the first event in good time. This was a motorcycle affair and was followed by the first automobile class, for cars costing $900 or less. From that time forward to the free-for-all it was somewhat of a field day for the Buicks, which were hauled into Atlanta on the tail of the "Florida Flyer" the day before the race. With such old celebrities as Strang and Burman, and with the newest discovery, Dewitt, all fresh from Daytona, they swept away three out of five firsts in the "limited price" classes. A little E-M-F. won in the big second class, covering the hill in 1:08 and defeating a field of ten starters.

Class 3 for touring cars costing $1,500 or less, was a safe victory for a Pope-Hartford. The individual hero of the day was Jones, nicknamed "Daredevil," a local boy, who drove the two winners last named.

Here is the summary:

Class 1 (cars costing $900 or less).—Buick, Travis, 1:15, first. Buick, Cantrell, 1:21, second; Ford, Hule, 1:23, and Ford, Brown, 1:23, tied for third; Lambert, McNeal, 1:49 4-5, fourth.

Stearns, Almand Driving, Best Gasoline Performer.

Class 2 (cars costing $1,500 or less).—E-M-F, Jones, 1:08, first; Buick, Chalker, 1:11 1-5, second; Buick, Travis, 1:14, third; Buick, DeWitt, 1:14 2-5, fourth; E-M-F, Atkins, 1:15 1-5, fifth; Ford, Brown, 1:21 1-5, sixth; Chalmers-Detroit, Smith, 1:22 1-5, seventh; Lambert, McNeal, 1:24, eighth; Ford, Hule, 1:28 1-5, ninth; Overland, Stewart, 1:29 2-5, tenth.

Class 3 (for touring cars costing $3,000 or less).—Pope-Hartford, Jones, 1:04 4-5, first; Pope-Hartford, Stoddard, 1:05 1-5, second; Buick, Burman, 1:08, third; Selden, Woodam, 1:19, fourth.

Class 4 (for runabouts costing $3,000 or less).—Buick, Strang, :58 3-5, first; Stevens-Duryea, Henderson, 1:02, second; Ford, Hule, 1:05 4-5, third; Maxwell, 1:15 2-5, fourth.

Class 5 (for touring cars costing $5,000 or less).—Buick, Burman, 1:04 4-5, first; Pope-Hartford, Stoddard, 1:05, second; Pope-Hartford, Jones, 1:06, third.

Class 6 (for runabouts costing $5,000 or less) called off for lack of three starters.

Exhibition, Buick runabout, Strang, :59.

Class 7 (free-for-all).—White Steamer, Lambert, :45 4-5, first; Stearns, Almand, :48 2-5, second.

White Wins San Francisco Hill Climb.

San Francisco, March 29.—In the hill climbing carnival held here to-day, a 20-horsepower White Steamer made the fastest time of the day. It was barred from stock car events, but a special match race was arranged between it and the winners of the stock races. This it won, its time for the mile being 1:12 2-5.

DATE SET FOR LOOKOUT MOUNTAIN CLIMB.

Chattanooga, Tenn., March 29.—Chattanooga's great mountain climb, up historic Lookout Mountain, has been set for April 22, and active preparations are now being made by the Lookout Mountain Automobile Club for holding the event, and for entertaining the large number of visiting autoists. The contest has been given the support of the Chamber of Commerce of this city, and six handsome trophies have been donated by large social and commercial organizations. The program will include events for seven different classes of stock machines and a free-for-all.

Lookout Mountain stands over 2,000 feet above the city of Chattanooga, and the course will be from the bottom to the summit, a distance of four miles by a road which is replete with hairpin, triple S and W turns. It is pronounced as the most dangerous and difficult climb ever scheduled, and will rival those of Giants' Despair at Wilkes-Barre, Pa., and of the Climb to the Clouds upon Mt. Washington, N. H. It will be equally picturesque.

INDIANAPOLIS HAD A BIG WEEK.

INDIANAPOLIS, IND., March 30.—Local dealers estimate that the number of automobiles sold during the annual spring opening last week had an aggregate value of $450,000. Not less than 300 cars were sold during the week, and of these a large proportion were touring cars costing above $2,000.

The show concluded Saturday night with a banquet at the Denison Hotel. Mayor Charles A. Bookwalter was the guest of honor, and delivered the principal address. Other talks were made by dealers, manufacturers, and their friends.

Under the auspices of the Indianapolis Automobile Trade Association, an egg race and tire changing contest were given Tuesday afternoon, while a parade and an obstacle race were held Friday afternoon. Inclement weather necessitated changes in the program. The results of the various contests were:

Egg Race—Buick, driven by Mr. and Mrs. W. V. Peterson, first, time, 33¼ seconds; National, driven by Thomas Kincaid and Miss Mary Aitken, second, time 35 seconds.

Demountable Tires and Rims—Won by Edgar Apperson, driving an Apperson equipped with Diamond demountable tires and rims; time, 1:43.

Clincher Tires—Won by Charles Starr, driving a Premier equipped with Diamond clinchers; time, 2:59.

Detachable Tires—Won by T. K. McCune, driving an Auburn equipped with Goodrich detachable tires; time, 2:09.

Obstacle Race—Won by George L. Bixby, driving a Waverly electric, distance two squares, perfect score; time, 1:06.

Because of rain it was necessary to postpone the parade until Friday afternoon. More than 350 cars were in line, including everything from $500 runabout to a three-ton truck. The Indianapolis Motor Car Company was represented by 50 Rapid trucks that are in daily service in the city. These included the police patrol wagon. The city dispensary ambulance, just completed by The Waverly Co., was also shown for the first time.

There were two bands, both riding on trucks. One of these was a "rube" band in grotesque costumes.

There were 47 Overland cars in the parade, entered by the factory and by the Fisher Automobile Co. These included all of the models manufactured by the company.

The Premier, National, Marmon, and American factories, as well as the Cole Carriage Company, were well represented. Each car was filled with its full quota of passengers, while the commercial cars were loaded with merchandise.

E-M-F Which Scored in Class Costing $1,500 or Less.

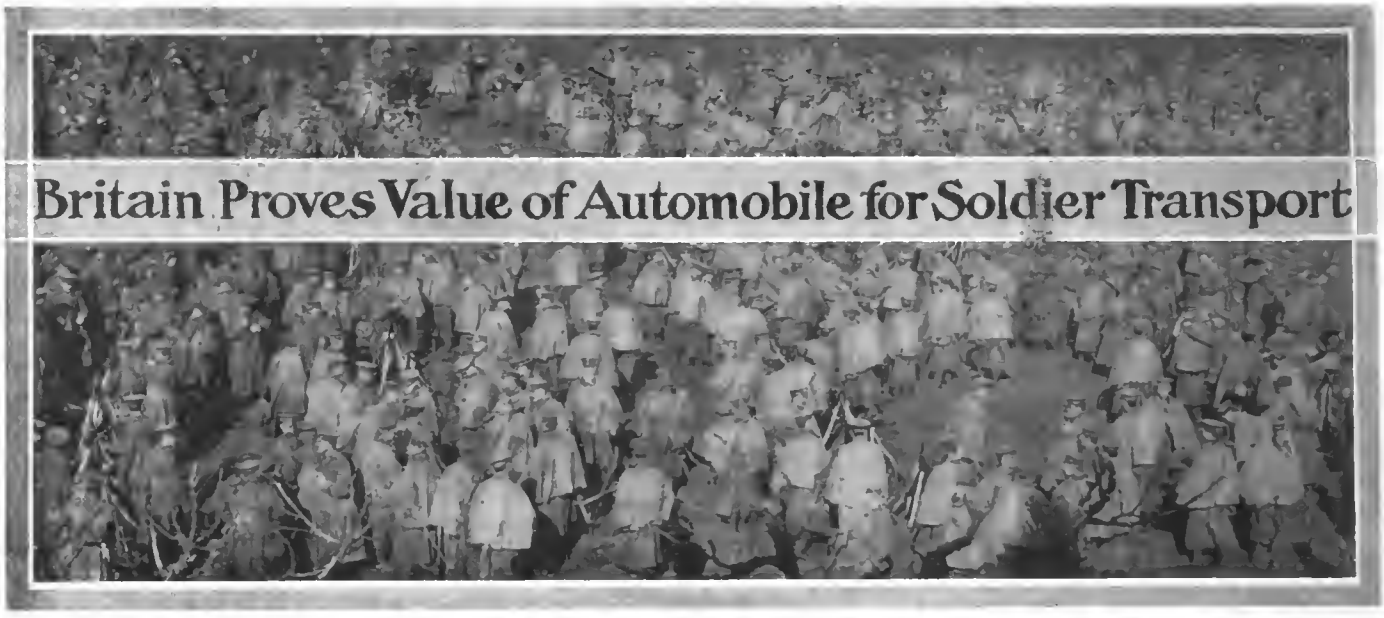
CLEVELAND'S QUOTA FOR GLIDDEN TOUR.

CLEVELAND, March 29.—Cleveland may take an active part in the 1909 Glidden tour, although if the local manufacturers do not display more interest than at present, it is doubtful if the entry list from the Forest City will be overly large. What the Peerless people will do is not yet known, but the general impression is that the Peerless will not be found in the 1909 run. No definite announcement has been made to this effect, however. Nothing is expected of the Stearns, although the influence of Chas. B. Shanks may alter things somewhat. The Winton people are out of all contests, of course, while the Royal is looming up as a dark horse. It is said that considerable pressure will be brought to bear on the officers of the new company to enter the contest.

Entries are confidently expected of the White stemer. Last year the Whites were ready to start for Buffalo when a change in the plans were made. The White people, following their usual custom, will make no formal announcement of their plans, but to see Walter C. White and others in White cars cross the starting tape will surprise no one. At least one entry, that of Paul Gaeth, is assured, and he may increase this. Mr. Gaeth had a perfect score last year, and is in favor of entering again this season. There is a chance that the Studebaker entries, if they are made at all, will be from this city.

There Were Those Who Must Be Exactly at the Finish Line, which, of Course, Was the Storm Center.

Britain Proves Value of Automobile for Soldier Transport



Troops Assemble in Preparation for Overland Journey to the Southern Coast of England.

LONDON, March 18.—To prove the extreme value of automobiles for the rapid transportation of troops in time of war, the Automobile Association yesterday conducted what was probably one of the most important happenings in the history of all England, by conveying a detachment of 1,000 troops, with full stores and equipment, from this city to Hastings, on the South coast, and return on the same day. The presumption was that an enemy had landed, where "William, the Conqueror" put in his appearance 813 years ago, and had occupied the railroad, so that there would have been no quick method of transportation without the use of automobiles.

The War Office showed a great interest in the scheme, and a battalion of His Majesty's Guards was detailed for the experiment, consisting of over 1,000 men, with machine guns, baggage, food and stores, weighing over 30 tons. The automobile trade and members of the Association responded to a really remarkable degree, and actually over 400 cars were assembled, to take part in the wonderful demonstration, not only of the practicability of the machines, but also of the thorough organization of the Association. The big squadron was divided into eight sections, each with a different colored flag to designate the cars, and there was hardly a hitch in the plans for the day. Even the farmers and others on the route, who were requested to refrain from traveling upon the highways, complied with the request, and almost no vehicles obstructed the progress.

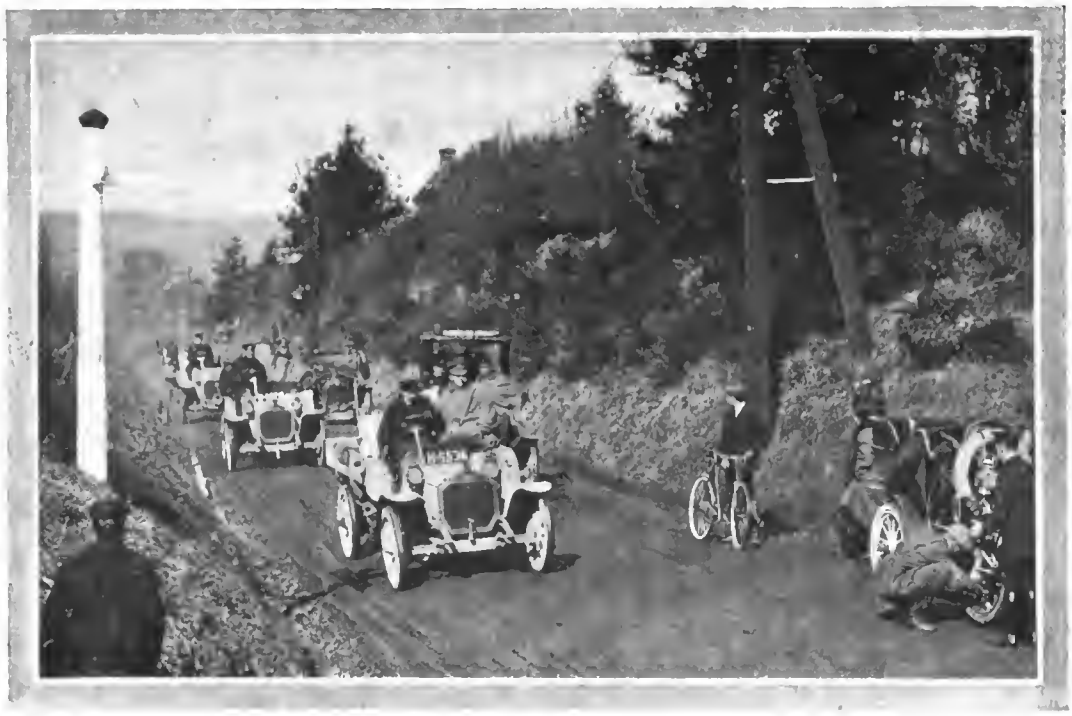
Start of Automobiles from London.

The first section, A, consisted of 12 automobiles, used by Lieut.-Col. Erskine, scouts and headquarters of the battalion; with the commanding officer, his adjutant, signaling officers, and bugler in one of them, and two vehicles were reserved in case of breakdown. Section B consisted of 65 automobiles, carrying two companies of the 1st Scots Guard under Captain Van der Weyer; section C included 66 cars, with Captain J. B. Arbuthnot and two companies of the 2d Scots Guards; section D was also made up of 66 cars, with one company each of the 2d and 3d Grenadier Guards, under Captain Vivian, of the former; section E, 66 cars, with two companies of the Coldstream Guards, under Captain Stewart, completed the division with the main body of troops. Section F was composed of 7 touring cars and 21 light lorries, and was known as the machine gun section, inasmuch as it carried the reserve ammunition, light artillery, personnel, all stores for the first line transports and two water carts, under the command of Lieut. Maitland of the 2d Grenadier Guards. Section G had four touring cars and 7 three-ton lorries (trucks), to carry the personnel and stores of the second line of transports, under Lieut. Barrington-Kennett of the 2d Grenadier Guards. The eighth section was really a free-lance one, carrying officers of the General Staff and other military authorities.

The first preparation for the event was made on Tuesday afternoon, when in 45 minutes 21 light lorries, five 'bus chassis with platform bodies, and three large three-ton vehicles were loaded with the stores, ammunition, etc., at the Chelsea Barracks, and then put under shelter for the night. These machines carried all kinds of impedimenta, such as kitchen utensils, trenching tools, bedding, the commissariat department, besides the guns. The first move on Wednesday, yesterday, morning was made by section G, which left the Barracks at 7.30, and proceeded to a point near the Crystal Palace where mobilization was to take place; joined soon after by sections A, B and C, which left the Wellington Barracks at 8.45, 143 cars being in line. In divisions B and C there were half a dozen empty cars for emergency.

Section D, E, F and the others soon formed and at 9.45 the bugle was sounded for the first car to get under way, the organization being so well regulated and completed that by 10.15 every one of the nearly 400 machines was en route to Hastings, and there had been little friction in getting them off. One car had a puncture, another caught on fire and a third had motor trouble, and the spare cars then had a chance, but these incidents were almost unseen in the great number. Only once did a section get out of place, a part of D leaving slightly ahead of its position, but this was quickly rectified, and the trip successfully continued. All along the route the soldiers were heartily cheered by towns-

folk and countrymen, and the men in the cars seemed to thoroughly enjoy the novelty of their outing. A great many of them were having their first ride in automobiles, and little appeared to realize that there was another significance in the performance, other than that of a mighty pleasant day's ride to the coast. The drivers of many of the cars were well-known autoists, business men and sportsmen, who seemed to enjoy the run as much as the Guards. Of course there was a large delegation of professional chauffeurs. The majority of the cars were donated by the private members of the Association, as distinguished from the trade, and there was little effort made by dealers represented to advertise their cars.



Part of Artillery Section, in Commercial Cars, near Penbury.

Arriving at Hastings, the troops quickly left the machines and formed in company lines along the roads. A short drill showed that they would be immediately ready for action, if necessary. The whole body of men was entertained at dinner, not a single cent having to be expended by the War Department in the entire program. The troops reassembled on the Cricket Grounds, and the return to London started at 3 o'clock, reaching the barracks by seven.

BRITAIN'S BIG CLUB ISSUES EDICT.

LONDON, March 18.—For several years the Royal Automobile Club has barred all trials and non-stop runs, save those held under its direct supervision. There have been occasional evasions of this rule, but now the Royal Automobile Club has taken a firm stand, and any maker who arvertises the result of an unofficial trial, whether such trial was run by themselves or not, will be debarred from entering for any future competition of the club.

In addition to the annual reliability trials of the Scottish and Irish automobile clubs, a small car trial will probably be organized by the Royal Automobile Club this Summer. The trial of headlights will also be held. During the coming week an interesting trial is to be made of the new Daimler engine. Under close supervision of the club officials a 38-horsepower engine will be run on the bench at full load for seven days and seven nights without a stop. At the end of this time the engine will be erected on a chassis and run for 2,000 miles at Brooklands at top speed.

The strong outcry last year against the use of racing cars on public roads is having a marked effect on the prices of second-hand automobiles of this type. During the past season many of the famous victors of previous years' contests have changed hands at low figures, but the limit was about reached at a sale here last week. A 135-horsepower Mercedes which ran in the 1907 Grand Prix changed hands for $2,700, while a 120-horsepower Mercedes, dating from the 1906 race, brought $2,350. The price of a runabout—$1,200—made some speculative individual the proud possessor of a 90-horsepower Mercedes of no great age, and at the same figure a 100-horsepower Darracq, which won the Montague cup at Brooklands, is still awaiting a buyer. If the speed craze is still in vogue in the United States, buyers will find much to interest them on this side of the water.

Military Rush of Men and Cars Through the Town of Penge.

Records Numerous in Floridas Meet

BY R. F. KELLEY.

Where the Cars Lined Up for the Start of the 100-Mile Stock Car Race on the First Day of the Meet.

DAYTON, Fla., March 27.—If the breaking of records is the standard by which the seventh annual tournament of the Florida East Coast Automobile Association is to be measured, it will go down upon the pages of history as one of the best of its class. Certain is it also that the attendance of the general public was never as large. In the matter of entries of the "big fellows" the field was small but "classy," though in the stock car race and the handicaps there was plenty of competition of a highly exciting nature. The motorcyclists and bicyclists added much to the entertainment, and made some good competition, as well as accomplishing much in the matter of establishing new records.

Certainly Mother Nature was in active sympathy with the management, and did her best to place the hard-sand course in the most perfect condition. A stiff northeasterly breeze on Monday tossed the breakers high on the bench and made it as smooth as though it had been shaved with a planer. On Tuesday, the opening day of the tournament, the wind veered to the south and came straight up the course, and this condition continued Wednesday. Thursday the wind was from the west, but it was limited in quantity and of no particular aid or detriment to the contestants. The day the programme was completed, Friday, there was a breeze directly from the east, which was at times chilly, and which later veered to the southeast and helped some to bring the competitors up the stretch in very fast time.

Where and to Whom the Honors Went.

To the 120-horsepower Benz, which successfully captured three world's records, belongs the first honors of the meet. It went out of commission with a broken piston at the conclusion of the second day, but not until David Bruce Brown had set a new world's mark in the amateur class for the mile of 33 seconds flat, and had placed the professional competition record for ten miles at 5:14 2-5, an average of 31 and 44-100ths seconds to the mile, and at the rate of 114 1-2 miles per hour. George Robertson, who last fall drove the Locomobile to victory in the Vanderbilt Cup race, piloted the Benz in one race, the five-mile invitation, and set a new competitive mark of 2:45 1-5. True, the Benz did not have an opponent that was in its class, Kilpatrick's Hotchkiss having become disabled early in practice work, and the Fiat *Cyclone* was its only competitor, but this fact detracts nothing from its notable speed accomplishments.

Louis Strang's victory in Class D, in the stock-car race, was well earned, and his new mark of 1:34:00 1-5 for 100 miles justifies the judgment of the Buick people in engaging him for the coming season. Robert Burman, his teammate, had hard luck in the stock-car race, the flywheel of his engine coming off and making a bee line for the ocean. He escaped without personal injury, but the car was placed *hors de combat.*

Excellent Work of the Two-Wheelers.

The riders of the two-wheeled motor-driven machines have every reason to look with pride upon their achievements. Premier honors went to Walter Goerke, of Brooklyn, who, on Wednesday in the five-mile straightaway trials, reduced the record to 3:30 1-5 for that distance. This was followed on Thursday by another successful onslaught on the record table by Goerke, his first performance being a lowering of the kilometer mark to :27 4-5, and his second the winning of the one-hour record race for motorcycles, in which he clipped a large slice off the Brooklands track record of 68 miles, 1,380 yards, by traveling an even 69 miles in 58:25 4-5. The course was measured with a view of timing the competitors at 69 miles, and there was no means of knowing what distance Goerke had covered at the end of the hour, though there is little doubt but that it was over 70 miles. A. G. Chapple, of New York, suc-

The Crowd that Lined the Beach and the Grand Stand, as Seen from the Stairway of the Club House Landing.

ceeded in lowering the ten-mile competition mark on Friday by placing new figures at 17:25 1-5. He also won the five-mile open on Wednesday. New record for the mile straightaway was set by Robert Stubbs, an amateur from Birmingham, Ala., on Thursday, the time being :43 2-5. All of these records were made on Indian 7-horsepower machines.

Much interest was shown in the bicycle events which were sandwiched into the programme, as most of the officials and drivers have been at one time or another identified with the time-honored cycle, either in the industrial or competitive field. On the last day of the meet DePalma fitted up his Fiat *Cyclone* with an improvised windshield, and a series of trials were made at the mile straightaway, the bicyclists using the auto as a pacemaker. Elmer L. Collins, of Lynn, Mass., riding close to the pace, covered a mile in :58 3-5, just four-fifths of a second away from the record of Charley Murphy, of 0:57 4-5, made behind a railroad train on Long Island some years ago. The competition between the cyclists was good, and several records were established, the most notable of which was by Joseph A. Fogler, of Brooklyn, who won the flying start half-mile from a field of ten in :47 1-5.

The Aeroplane That Did Not Fly.

Aeroplanist Bates, who brought his flying machine all the way from Chicago to try a flight over the beach, secured but one chance to try out his "white wings" during the tournament. This was at the close of the races on Friday, when the wind had died down to practically nothing. When the aeroplane emerged from its shed a great crowd gathered to watch the trial. The machine started smoothly and ran upon its carrying wheels down the beach for some distance, but failed to rise. The motor worked intermittently, and the gathering darkness made adjustment impossible. The aeroplane was run back to its house for the night Mr. Bates expects to make further attempts at flight before he leaves Daytona. The heavy winds the first part of the week made an earlier attempt impossible.

As the Parade Started from the City Hall.

Passing Over Halifax River Bridge to Beach.

Automobile Parade Was a Wealth of Color.

The automobile parade of Wednesday morning was a decided success. There were over fifty cars in line, and the procession left the City Hall at 10 o'clock in the morning, moving through the principal streets and continuing across the bridges to Daytona Beach and Sea Breeze, came to a termination in front of the clubhouse of the Florida East Coast Automobile Association and official stand. The first prize, a handsome trophy offered by the Daytona *Daily News*, was awarded to M. B. Aultman's Buick, which was decorated with heliotrope. Second honors went to Miss Jessie Brown, whose car was trimmed in luxuriant green, and the third prize was carried off by Miss Bessie Bingham, in her Cadillac, which was decorated in red, green and white. The parade was the best thing in that line that Daytona has ever witnessed, and Chairman White, who headed the committee in charge, handled the affair admirably.

Happenings of the Two Closing Days.

Thursday's programme of automobile events promised to go by the board, after the disaster to the Benz piston. Work was continued all Wednesday night to make repairs, but there were not sufficient mechanical facilities to get the car into working order, and as Kilpatrick's Hotchkiss was still out of commission, the Fiat *Cyclone* had a walkover in the one-mile invitation. De Palma drove over the course in :37 2-5. As the Buick team left town early in the morning to attend the hill climb at Atlanta Saturday, the management became busy and organized two four-mile handicap events with impromptu entries. These races proved to be the most interesting of the meet in a competitive sense. Start was made at the tape, and the course was two miles south and return. Inglis M. Uppercu, the well-known New York Cadillac representative, won the first handicap with a 30-horsepower Cadillac, his allowance being 1 minute 5 seconds; time, 5:03 2-5; M. Hotchkiss, 30-horsepower Pope-Hartford, 50 seconds handicap, was second, and Mr. Seamans, 30-horsepower Stoddard-Dayton, 30 seconds handicap, was third. The second handicap resulted in a win for the Pope-Hartford, after its handicap had been reduced to 30 seconds, in 5:05 3-5; DePalma, driving Fiat *Cyclone*, from scratch, was second, in 3:16; and Seamans, Stoddard-Dayton, 30 seconds, was third.

The balance of the programme was made up of motorcycle and bicycle events, some of which resulted in records, and which are referred to above.

The programme for Friday consisted of the excess of numbers on the programme that had been crowded from the previous days of racing. The event of importance was the 100-mile race for the Minneapolis Trophy, which had to be won twice to insure its permanent possession. Last year the late Cedrino piloted the Fiat *Cyclone* to victory in this event, and this year Ralph DePalma was at the wheel in the same car to secure a second and final hold on the trophy. As it was, he had a walkover, as no other competitors lined up at the tape. He did not go after the 100-mile record, but drove a limited distance over the course, under the instructions of Referee Miles, who awarded him the race. DePalma also had a walkover in the one-mile invitation.

An eight-mile handicap, four miles out and return, brought out a field of eight starters, with DePalma at scratch, conceding

Referee Miles Surrounded by His Official Assistants.

starts ranging from 1 minute and 20 seconds to 4 minutes. He won handily in 8:45, and was followed over the tape by the Hotchkiss Pope-Hartford, which won considerable glory as a persistent starter and finisher. Mr. Aultman's Buick was third.

A neck-and-neck finish was furnished by A. G. Chapple and Walter Goerke in the 20-mile motorcycle race, in which the amateur competition record was broken by the former. It was either man's race up to the finishing line, but Chapple managed to get the best of the Brooklyn favorite.

Next Year Last Week in January.

Formal announcement was made on Thursday that the eighth annual tournament will be held next January, probably during the last week of the month. It is proposed to raise a large sum of money for cash prizes, so as to attract a representative number of world-famous drivers. Major A. D. Foster, president of the East Coast Automobile Association; Secretary T. E. Fitzgerald, and Treasurer Edward White are indefatigable in their efforts to perpetuate the annual contests on the beach, and will undoubtedly be substantially backed by the citizens of Daytona.

At the conclusion of the racing on Friday evening Manager W. J. Morgan entertained the officials of the meet, representatives of the press, and a number of leading citizens at a banquet at the Café Mills, on Beach street. Other guests present included the leading lights of the Brooklyn National League baseball team, which organization came down from Jacksonville that morning to give an exhibition game of ball at Harrison's Park. Referee Samuel A. Miles officiated as toastmaster, and there was speech-making galore. It was a graceful and fitting finish for the week of festivities.

Earlier in the week, on Monday evening, a dinner was tendered at the Café Mills to Robert Burman by the Buick people, at which a handsome solitaire diamond ring, given by the company, and a gold watch, subscribed for by the other members of the Buick racing team, were presented to him. A typical Southern menu was served.

The Daytona *Daily News*, which is an evening paper, showed sterling enterprise during the week of the meet by issuing a special morning edition devoted almost exclusively to the tournament and the accompanying festivities. Secretary Fitzgerald, of the East Coast Automobile Association, who is also the editor of the *News*, certainly showed an energy characteristic of metropolitan dailies in the general make-up and reliability of his journal.

WILDWOOD WILL HAVE RACES IN JULY.

Wildwood-by-the-Sea, N. J., March 29.—The Contest Committee of the Motor Club of Wildwood has selected Saturday and Monday, July 3 and 5, as the dates for its first race meet of the present season. The races will, as usual, be run off over the Central avenue boulevard, which provides one of the finest mile straightaway courses in the country, and will include, besides the usual class events, trials for record, open to all.

MAXWELL NOW AHEAD OF WORLD RECORD.

Boston, March 31.—In its endeavor to cover 10,000 miles without stopping its motor, the Maxwell touring car which started this contest on March 18, has now accomplished half of that distance without trouble, and has beaten all previous records for non-stop runs. To-day, at noon, its mileage was 5,289, and the car is continuing on its second half as easily as on its first. No stops of any kind have been made except to change crews, repair one puncture, and to replenish fuel. The first week was spent in running between this city and Worcester, making 3,000 miles over that route; then the course was changed to Providence and return, over which it is still running.

ST. LOUIS AERO CLUB MAKES ACTIVE PLANS.

St. Louis, March 29.—For the promotion of aeronautics as a science and sport, the board of governors of the Aero Club of St. Louis has resolved to spend between $15,000 and $20,000 this year, instructing a committee to secure at once permanent ascension grounds, with facilities for obtaining coal and hydrogen gas inflation, and to buy a new 78,000 cubic feet capacity racing balloon. This balloon will be entered in the first championship balloon race of the Aero Club of America, from Indianapolis on June 5, with A. B. Lambert as pilot and H. E. Honeywell as aide.

To assist inventors of aeroplanes and dirigibles, the club has decided to purchase an aerial motor, which will be loaned to any inventor, whether a member of the club or not, for use in this vicinity. It will be a water-cooled engine of 30 horsepower, but has not as yet been selected. It is understood that a course in aeronautics will soon be started at the central branch of the Y. M. C. A., and the club will endeavor to aid this in all possible ways. The club plans to hold a carnival during the week of October 4.

Trio of Motorcyclists that Annihilated Records on the Daytona Beach Course—Chapple, Goerke, and Stubbs.

SAFETY AND UTILITY OF AUTOMOBILE STEERING SYSTEMS

PART IV

By Thos. J. Fay

SHOCK to the steering crank, on the knuckle of the front road wheel will be more or less, depending upon the design, an intimation of which was given in the closing paragraph of the last published part of this article, and Fig. 31 is here given to more clearly indicate the manner in which such shocks can be minimized. The section, Fig. 31, is of a design in which it is shown that the center line of the wheel, OA, and the center line of the knuckle O'A' do not bisect at the point of contact of the tire with the road, and the result is that a crank moment will generate, the magnitude of which will be proportional to the difference as shown at O and O'.

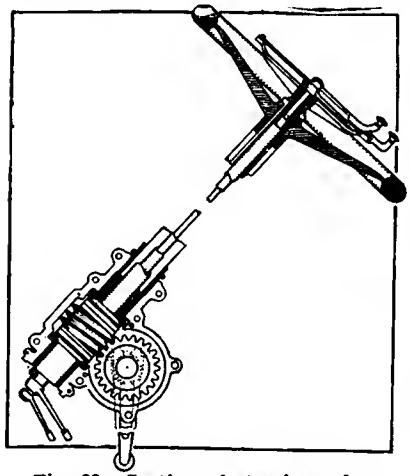


Fig. 33.—Section of steering column, showing concentric parts for advancing spark, and throttle.

The magnitude of the crank-arm moment due to the deficiency O and O', while it will be in proportion to the difference, as before stated, will also be capable of influencing the car performance in a manner depending upon the diameter of the front road wheels, as they relate to the height of road obstructions to be negotiated in the regular course of events. In the absence of road inequalities of a magnitude sufficient to influence the situation, it is a matter of no moment as to whether the conditions, as they are depicted in Fig. 31, obtain or not.

It is when the steering road wheels intercept an obstruction of a relative great height that the difference noted in Fig. 31 becomes a menace. On the other hand, it is not convenient to reduce the distance OO' to zero, and it is therefore desirable to use road wheels of a good diameter, and reduce the distance OO' to the minimum besides.

Worm and Sector Types of Steering Gear.—In this type of steering gear it is usually the practice to use multiple thread worms, a good example of which is shown in Fig. 32. The quadruple thread depicted affords good proportions of the teeth, the angle is as close to the irreversible as it is desirable to go, the surface of actual contact is quite enough for good work from the point of view of long life, and this particular gear has seen some nine years' service to its credit in cars that have made and maintained a reputation for minimum upkeep, and good road performance.

In some cases the sector is left out and instead the whole worm-wheel is used, in the manner as shown in Fig. 33, which figure also depicts the section of the steering column, and the way in which the details are worked out. This is illustrative of general practice, in which concentric tubes are used thus:

(a) The outer tube is of thin brass, does not rotate, and serves as a spacer, as well as holding the bearings in rigid relation. Brass is used, and kept polished, to enhance the general appearance of the car.

(b) The second tube is in rigid relation to the worm and the steering wheel, so that, if the wheel is rotated so will the worm rotate, which in turn causes the sector to respond, hence the steering crank, which is also in rigid relation.

(c) The third tube serves for the spark, and is rotated besides connecting with a lever on the top of the steering column, above the steering wheel, for the convenience of the driver.

(d) The inner member in the concentric nest can be a rod, although it may also be a light tube of small diameter, and if the member (c) is connected with the spark, it is then that the inner rod will be for the purpose of controlling the throttle. It is usually a matter of convenience that influences the selection, as between spark and throttle.

It will be understood that a wide variety of worm and sector details will be found in cars as they can be seen in actual practice, and it is probable that the wide selection to be noted in no way interferes with the good results to be expected. In steering equipment the results, like in ball bearings, will depend largely upon materials used and fine workmanship to a vast extent. Likewise, in the operation of a car, if the equipment is not looked after, the details of design will have small bearing on the degrees of satisfaction, since lost motion will soon render itself manifest, and the car will become a source of annoyance to the driver, if not a menace to all who have to do with it.

Some Methods Used in the Design of Worms and Sectors.—Presupposing a worm and sector for the purpose, it follows that certain of the considerations must be settled upon before it will be possible to intelligently use any formulæ in arriving at the respective dimensions of either the worm or the sector. The arc of the sector will depend upon the canting angle of the front road wheels, and this cant depends upon the afforded room, taking into account the diameter of the road wheels, and the section of the tires to be used, as well as the distance from the wheel to the side of the chassis frame.

It will also be necessary to consider the relation of the steering wheel to the canting angle, in order to determine the number of revolutions of the steering wheel for a given (combined) canting angle. If the steering wheel is to make 1 1-2 revolutions while the road wheels cant the full sweep from right to left, this information must be in hand before it will be possible to apply any formula in the process of designing the worm and sector. Even in repair work it is desirable to review this situation, as well as the other considerations essential to the process.

In some cars it is the practice to so design the system that for one turn of the steering wheel the road wheels will cant the full (combined) angle. The main trouble about this plan lies in the

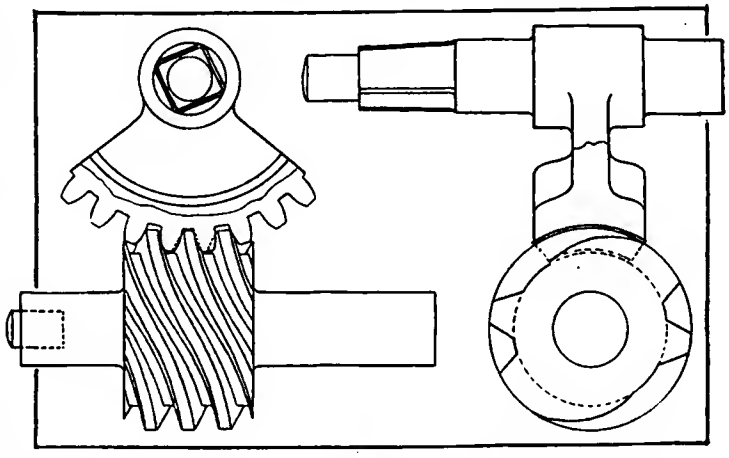

Fig. 32.—Example of worm and sector steering gearset, long used in good cars.

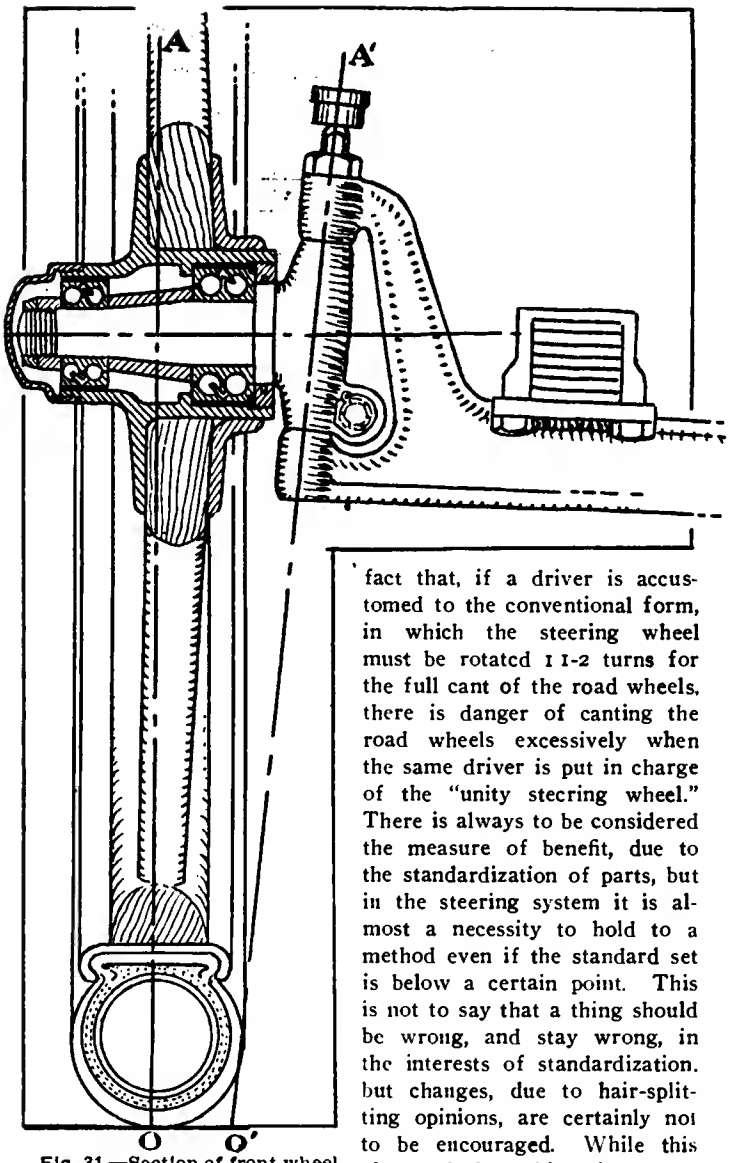

Fig. 31.—Section of front wheel, showing defect tn design whtch affects steering.

fact that, if a driver is accustomed to the conventional form, in which the steering wheel must be rotatcd 1 1-2 turns for the full cant of the road wheels, there is danger of canting the road wheels excessively when the same driver is put in charge of the "unity stecring wheel." There is always to be considered the measure of benefit, due to the standardization of parts, but in the steering system it is almost a necessity to hold to a method even if the standard set is below a certain point. This is not to say that a thing should be wrong, and stay wrong, in the interests of standardization. but changes, due to hair-splitting opinions, are certainly not to be encouraged. While this phase of the subject is on the tapis, it will be as well to discuss the steering wheel proper. as it relates to the wood rim used. If the rim is not securely fastened to the spider, there is a chance of it falling off at a critical moment, just when an incident, such as this, would tend to disconcert the driver, with such consequences as are prone to be the product of absent-mindedness under stress of strenuous circumstances. But if the rim is to be securely fastened, it is no less a fact that it should be of a suitable section to enable the driver to grip the same firmly, and it has been found that a round section is more likely to set up cramps in the muscles than will be due to an oval shape. As for the wood, it does seem as if mahogany is as good as it looks, and the looks may well be regarded as up to the standard of excellence not readily improved upon, if the mahogany is properly secured to a spider of good design, and suitable material.

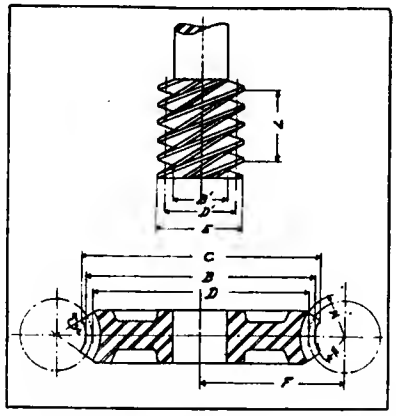

Fig. 34.—Diagrammatic figure of worm and sector used in designing formula.

After considering the details of the service, and having decided on the relation of the steering wheel to the road wheels, it is possible to use the formulæ of the worm and worm gear, one version of which is as follows:

$$8.\quad D = \frac{y\,P}{\pi} = 0.3183\,y\,P;$$

$$9.\quad B = D + 0.6366\,P;$$

$$10.\quad C = B + 2\,(N - N\cos A);$$

$$11.\quad F = \frac{D + D'}{2};$$

$$12.\quad D' = 2\,F - D;$$

$$13.\quad M = \frac{D'}{2} + 0.368\,P;$$

$$14.\quad N = \frac{D'}{2} + 0.3183\,P;$$

$$15.\quad E = D' + 0.6366\,P;$$

$$16.\quad B' = D' - 0.736\,P;$$

$$17.\quad \text{Tang. } S = \frac{L}{\pi D};$$

$$18.\quad L = P\,Z;$$

$$19.\quad P = \frac{L}{Z};$$

$$20.\quad Z = \frac{L}{P};$$

21. y = number of teeth in the worm wheel;

22. P = circular pitch;

23. S = lead angle in degrees;

24. tooth angle = 29 degrees.

The formula of the worm and sector will best be understood if reference is had to the diagrammatic illustration, Fig. 34, in which will be found the reference letters corresponding to the letters used in the formula. In relation to the material to use. it will be understood that there are several choices, as for illustration, the worm can be of cementing steel and case-hardened. The sector can be of phosphor-bronze. Alloy steel may be used for the worm, and the choice of cementing or quenching from some high temperature will fall to the lot of the chooser.

The cementing process has its advantages, and assures a hard surface, which is well worth taking into account. If alloy steel is used and the same is to be cemented, it is then that the carbon content should be low—very low indeed—and this is the kind of steel that is hard to get. Whether or not the material of the worm is to be of alloy or carbon steel, if it is to be subjected to the cementing process, the carbon should not be higher than 20 point, as an outside figure. For the rest it is largely a matter of personal choice, among the respective generic types of steel.

Some Products that Can Be Used.—Considering the cementing process, and allowing that the core of the cemented section should be tough and soft, the steels as follows might be selected:

Carbon Steel for Worms.—The chemical composition should be within the following and the steel should be of the acid process:

Carbon.	Silicon.	Sulphur.	Phosphorus.	Manganese.
.15-.20	.10-.20	.03-.04	.03-.04	.30-.40

The physical properties should be those due to proper fabrication of the steel, but it is hardly worth while to go over this phase of the question for the reason that the steel will be so altered in the cementing process that it is a well-fabricated

product, the end will be that due to cementing, which is bound to represent a decided improvement.

Cementing Nickel Steel.—In this grade of steel there is so much chance of going wrong that it is a question if it is worth while taking the chances, unless access can be had to some well-known grade of steel in which the imperfections that do abound in nickel steel will be more nearly absent.

At all events the steel should be an acid product with the carbon positively within the limits here given:

Nickel.	Carbon.	Silicon.	Sulphur.	Phosphorus.	Manganese.
4.5	.10-.15	.15-.20	.03-.04	.03-.04	.30-.40

Physical Properties.—The elongation should not be less than that as here given, with the steel in the normal state:

Elastic limit in pounds per square inch (minimum).....60,000
Tensile strength in pounds per square inch (maximum)....90,000
Elongation, per cent. in 2 inches (minimum)..... 30
Reduction of area in per cent (minimum)..... 69

In this work the test proof should be 0.5 inches in diameter, and it would be of advantage to experiment with some of the steel, before and after cementing, with a view to ascertaining the extent to which it will become brittle in the heat-treatment. Some grades of nickel steel behave better than others in this service, and in not a few cases it was found that the steel could not be safely used at all. It is in repair work especially that care should be exercised, since in the maker's plant much experence generally eliminates the troubles likely to arise.

Chrome Nickel Steel.—In this product there is ample opportunity to get into trouble due to high carbon, and such other irregularities as can readily fall to dual alloy steel. The remedy lies in not using the steel at all, unless the carbon is low, and provided the physical properties are quite up to the standard here set.

Chemical Composition.—With the understanding that the carbon will be lower, if anything:

Chromium.	Nickel.	Carbon.	Silicon.	Sulphur.	Phos. phorus.	Manganese.
1.4-1.6	4.40-4.60	.10-.15	.15-.20	.013-.015	.01-.013	.30-.40

Physical Properties.—Under no circumstances should the elonation be other than the value as here given, for the steel in the normal state:

Elastic limit in pounds per square inch (minimum)..... 90,000
Tensile strength in pounds per square inch (maximum)..110,000
Elongation, per cent in 2 inches (minimum)..... 22
Reduction of area, per cent. (minimum)..... 65

In the cementing process the penetration will not be exactly the same for the several grades of steel, but the chart (Fig. 26, Part II), will afford such information, in relation to the time, that nothing more will need be put down here, especially as this

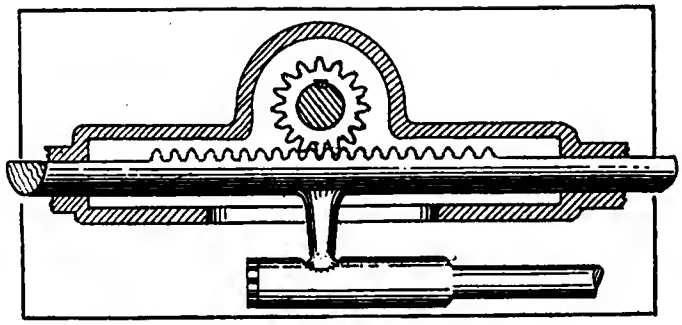

Fig. 35.—Characteristic sketch of rack and pinion.

phase of the subject can be taken up by the interested reader, as a separate matter to be investigated.

After cementation it is necessary to quench, and in the process there is every chance to go wrong. With some grades of steel the "single quench" will do, and the case will be hard, while the core will be soft and tough. In some examples the core will be rendered crystalline in the process that makes the shell hard, and the result will not be good. To eliminate this trouble it is necessary to put the parts through a double quenching process in the manner as follows:

(a) Quench at 900 degrees centigrate, in oil at the temperature of the surrounding.

(b) Reheat to 750 degrees centigrade, and then quench in salt water at the temperature of the surrounding.

In this way the core will be rendered tough and soft, while the shell will be quite up to the hardness likely to result from the use of the given grade of steel. As regards the efficiency of quenching baths, the media are given below in the order of merit:

In the cementing process it is not only a question of time that fixes the penetration, but the cementing material as well. It is not desirable to have the cementing material too intense in its action, and if the ground bone, or whatever may be the form of the carbon, is in 60 per cent. presence, the time will be fixed accordingly. At all events, it is the height of good practice to use some one grade of cementing material, and when a product is found for the purpose to get used to it, and stick to its use is in the path of wisdom. It is in making changes that mistakes are frequently made also.

Merit of the Respective Quenching Liquids Used.—The first-named medium (mercury), cannot be used with safety, excepting for very small parts, on account of the poisonous vapors

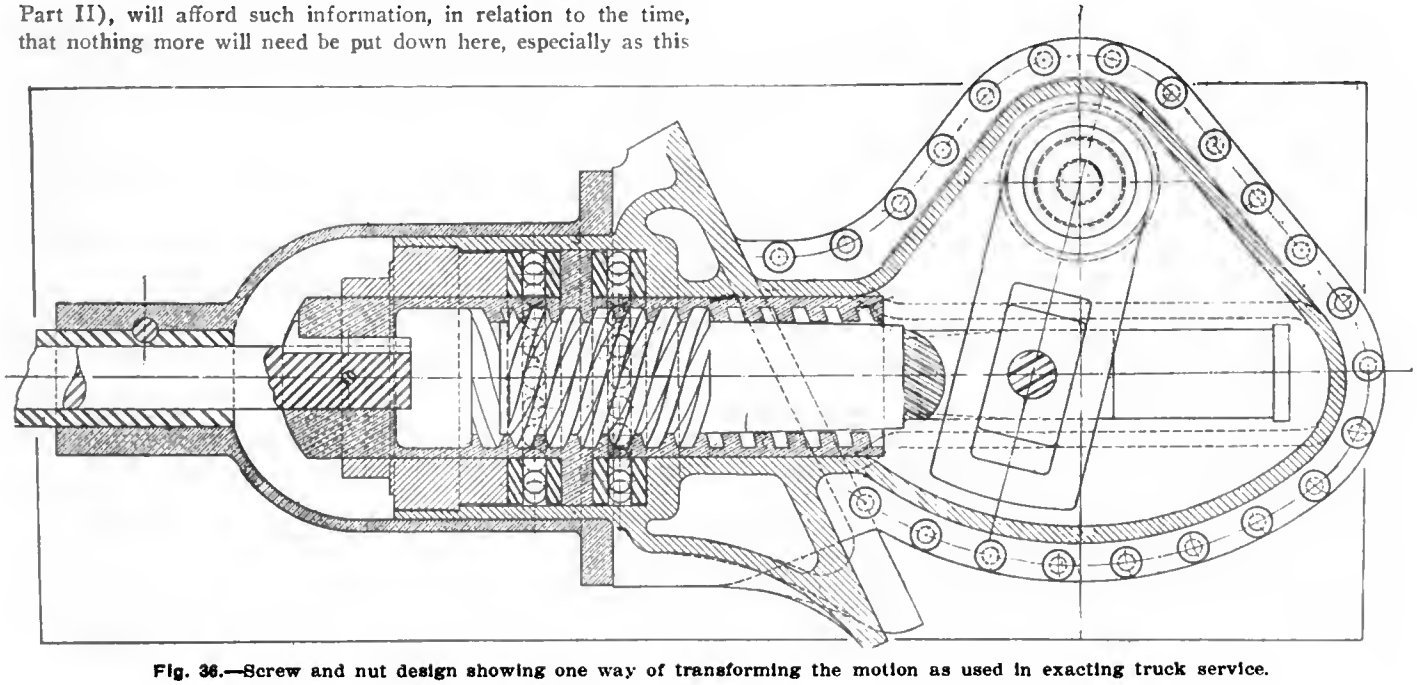

Fig. 36.—Screw and nut design showing one way of transforming the motion as used in exacting truck service.

emitted, and for that matter all heat-treatment work is attended by more or less risk.

(a) Mercury.
(b) Acidulated water, ice cold.
(c) Salt water, ice cold.
(d) Salt water, at surrounding temperature.
(e) Water, at surrounding temperature.
(f) Water, with skim-milk.
(g) Limewater.
(h) Fish-oil, or cotton-seed oil.
(i) Cod-liver oil.

(j) If some means is at hand for maintaining a constant temperature of the quenching bath, and if the parts are placed in a "jet" of the liquid, to wipe off the globules of steam, the efficiency will be much enhanced.

Since lost motion is the bane of the steering gear situation it is not believed that too much time has been taken in the act of indicating the manner in which the worm can be rendered as serviceable as possible, and the process of repair is certainly one that is well worth more than a little of the most careful attention. When the worm is so worn that flat spots are noticeable on the faces of the threads, it is generally better to cast the worm out and make a new one for the purpose

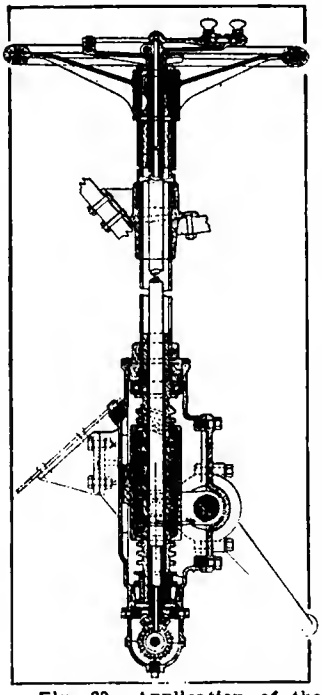

Fig. 39.—Application of the Acme principle to a steering gear set.

In worm and nut work there is a wide choice of threads, and means by which the motion can be adjusted to suit the requirements. In the mean time, it is something of a misfortune that the motion has to be transformed, since it leads to extra bearings and the possible lost motion so much to be dreaded. Square threads are used to some extent, but it is not desirable to resort to the use of the U. S. standard or any of the V shapes, since they do not assure easy action, and the surface is less than that which can readily be realized through the use of the Acme standard thread, which is much used in this class of work.

Rack and Pinion Form of Steering Gear.—This form of steering gear is used to some extent in commercial car work and in many respects it is to be commended. True, lost motion must be present to the extent that back-lash is a necessary property in the relations of the rack to the pinion. It is also true that the "lever advantage" will be less than that due to the use of the worm and sector, and irreversibility is entirely absent in this type. Fig. 35 depicts a conventional form of rack and pinion gear, which, with a pinion of the smallest possible number of teeth considering good practice, and a steering wheel of the greatest possible diameter, it becomes feasible to use the idea to fair advantage.

Screw and Nut Much Used in Practice.—While the worm and sector plan does away with any need of sliding bearings, such as are frequently used in connection with the screw and nut type of steering gear, the latter plan is much in vogue, and it has the advantage of a large bearing surface for the threads of the reducing members, and the sliding bearings, when they are used, are made with adequate surface for the purpose, Fig. 39 is a good illustration of one phase of the scheme, and while details of the respective plans are not always along parallel lines, even so, to the owner, and the repairmen, the deviation should not prove of undoing purport, and because the surfaces are a maximum, coupled with good facilities for lubricating, the evil

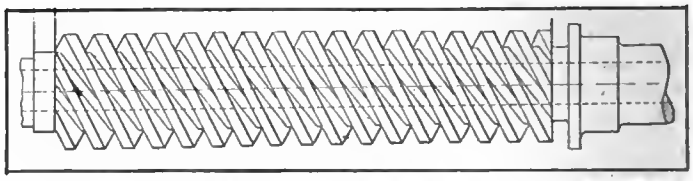

Fig. 38.—Illustrating a multiple thread screw of the Acme standard.

day should be much deferred and repairs should not be past the ingenuity of a man of fair skill, while the tools in the average shop should be adequate for the purpose.

Acme Standard Screw Thread.—In the class of work of the subject it is quite generally the practice to use the Acme 29 degree (included angle) thread, the data of which is as follows:

Width of point of tool for screw or tap thread,

$$25.\quad W = \frac{0.3707}{\text{number of threads per inch}} - \frac{6}{} - 0.0052.$$

Width of screw or nut thread,

$$26.\quad W = \frac{0.3707}{\text{number of threads per inch}}$$

Diameter of tap.

$$27.\quad d = \text{diameter of screw} + 0.020$$

Diameter of tap or screw at root,

$$28.\quad D = \text{diameter of screw} - \frac{1}{\text{number of linear threads per inch}} + 0.020$$

Depth of thread,

$$29.\quad B = \frac{1}{2 \times \text{number of threads per inch}} + 0.010$$

In this class of work, in the shop, it is of especial advantage to have at hand a "worm-thread tool gauge" conforming to the Acme standard, which gauge will serve to furnish the correct form in turning the thread or the worm. That this form of thread is quite up to a fitting standard is assured by the large number of steering gears in which it has found a resting place.

Fig. 38 shows a worm cut in accordance with the Acme idea, and Fig. 39 is a good example of the use of a screw and nut steering gear.

Before concluding, it will be the aim to advocate the presence of good materials in the component parts of steering gear, and such fine workmanship that the chances of trouble will be as a remote contingency, and even then under stress of the greatest provocation. Fig. 37 shows a steering system in which the cranks, linkages and the drag, as well as the tierod, are nested high up and back, out of harm's way.

In closing, mention will be made of one more type of steering gear, in which the planetary system is used in the head of the steering column. This form of gear is sufficiently irreversible for all practical purposes, and it nests so closely that it can be placed in the head of the steering column without rendering the appearance of the system nearly as bulky as one might suppose. In the planetary gear system there is little chance for lost motion if the work is fairly well done, and it is an advantage, the fact that the work has to be well done, in order to be able to assemble the gears. This system also affords a large amount of surface, so that the life of the gear is long.

In practice the system has made a good record and road-shock is effectively shielded.

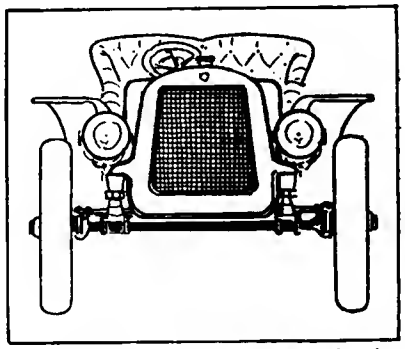

Fig. 37.—Front of a car, showing steering equipment out of harm's way.

Automobile Cooling Systems Analyzed

BY MORRIS A. HALL PART III

THE matter of the relative volume of air and water for equal cooling ability may be expressed in another way: that is, the ratio of the specific heats of the two being .2375, the ratio of the volumes is the reciprocal of this, or 4.2. The meaning is that to remove the heat from the water in the radiator by means of air it will be necessary to use 4.2 times as much, or if the efficiency of the radiator is taken into account, five times as much.

Fig. 8.—Appears like a square tube honeycomb.

Ratio of Air to Water a Big One.—This really is a very large ratio and one that would be difficult to obtain if the air and water passed through the cooler at the same rate of speed. However, that is not a condition that obtains in practice; in fact, the air is passed through at such a high rate of speed compared to the speed of the water that the volumes are very nearly equal. Thus the inherent inability of the air to remove heat quickly and efficiently is more than overcome by using an enormous amount of it passed through at a very high linear speed.

This brings up the question of efficiency per unit of frontal area. The space which can be given up to the radiator is always limited as will be explained later. This, in turn, limits the frontal area. Now, if the area is limited, the efficiency of this area must be increased to compensate for the lack. The latter, is effected in several ways, thus the depth may be increased, within certain well-defined limits. Or, the surface may be lengthened by corrugations, that is the internal surface, so that the water in passing through, must travel a longer passage. If an equal amount of air is presented all along the tortuous passage, the cooling effect must of a necessity, be greater. This works both ways, for if the other side of the tubes are also corrugated there is a greater surface exposed and the whole is more efficient.

The Two Classes of Radiators.—Broadly speaking, there are but two classes of radiators, also called coolers. These are the tubular type, in which the water passes through coils of tubing having a number of metal fins or gills fastened on the outer circumference. The second form is that known as the cellular honeycomb type. This consists of a flat tank pierced by a multitude of small tubes. In practice, these vary greatly not only among the different makers, but also between the different sizes and for dissimilar uses. The difference between the two types is but a difference in form, the one hot substance passing through the tube and the other, or cooling medium, circulating around the outside. There is, however, this minor difference, that in the two classes of radiators the heated fluid occupies, in one, the inside of the tube, while the cooling substance is outside, and in the other the one to be cooled is outside and the one used to cool passes through the tube.

These two general types have many and varied forms in practice; in fact, until the last year, the leaning was away from anything that savored of the commonplace or ordinary. This tendency resulted in a crop of different coolers, every maker had his own shape, and each one was made primarily distinctive, and secondarily for cooling purposes. Now, however, all that is changed, and with very few exceptions the front view of one car is not unlike that of many others. This has made recognizing a car impossible from a front view.

In Fig. 8 is shown a sample that many will recognize at once. This is of a popular medium-priced car, and the radiator is a clever attempt to produce the looks of the square tube cellular type at tubular price. As the comparative efficiency of the two has never been satisfactorily and definitely proven, this is no crime, but rather a good example of good looks and equal ability for little money.

Fig. 9.—Typical modern tubular cooler.

Figure 9 is another of the same kind, although the striving after the square tube is not so marked as before. The incurving corner ornament is more on the modern order of radiator distinction, and is typical of several of the best cars. In Fig. 10 is seen a real cellular with square tubes, and these set parallel to the ground. This, too, has what was called the Mercedes

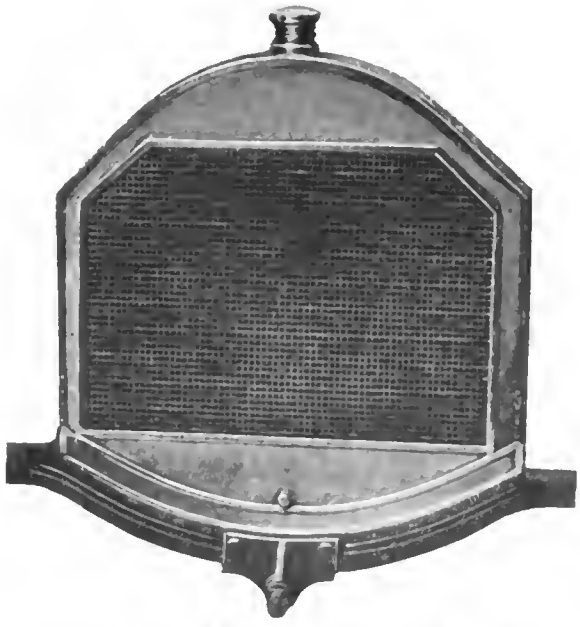

Fig. 10.—Square tube cellular of pleasing lines.

shape, from the firm which brought it out. This shape has now become general, and is no longer called by that name. The conditions which brought about the development of the shape are simple and easily understood.

How the Mercedes Type of Radiator Was Evolved.—When the tee head motor was developed, the ignition wires and water pipes over the top of the engine marked the high point of the outfit. The frame had a definite fixed width, the top of the symmetrical parts of the cylinders came at a certain distance above the frame, which parts had to be cleared by the hood. The high point being fixed, anything that went higher by more than reasonable clearance added unnecessary and useless weight. What was more natural than two straight lines sloping down to clear the cylinders and meet the vertical side lines? Upon close investigation, this is seen to describe the so-called Mercedes type exactly, with the addition of a long radius curve at the top to take off the curse of the straight lines.

This kind of a radiator has long been called honeycomb, and many people have wondered why. In Fig. 11 is shown one of the earlier radiator sections. This, it will be seen, is formed of a series of six-sided or hex tubes, fastened into a header in such a way as to allow of space between the tubes for the passage of water. It is a true honeycomb, and, although the hex tubes proved expensive and did not last, the name stuck and is used to-day to indicate all radiators in which a series of tubes are fixed into a header with water spaces between them.

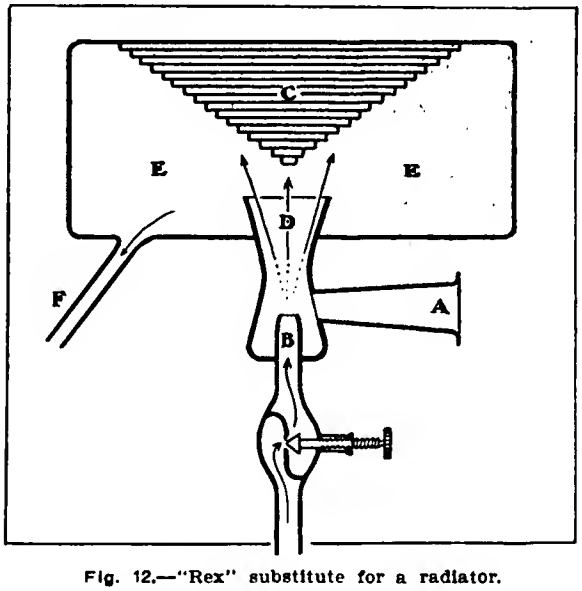

Fig. 12.—"Rex" substitute for a radiator.

Innovations Differ from the Standard Shape.—In stating that radiators are fast approaching a standard shape, the exception must, of course, be made that coolers intended to work along new lines or on a new principle usually take on a new and different shape. Thus, in Fig. 12, is seen a device brought out in France less than a year ago which would hardly be recognized as a radiator. That is what it was intended for, however, and a brief explanation of the principle upon which it works will be of interest.

The device consists of an entering tube of the shape of the Venturi meter, whose action is well known. Into this tube, at the proper point, the hot water is forced at a very high pressure, much higher than is ordinarily used, and amounting to perhaps 50 pounds per square inch. This powerful jet of water issuing into the venturi tube *D*, expands suddenly from its high pressure down to atmospheric, while at the same time the rush of water draws in a large volume of cold air at the opening *A*. The sudden expansion of the water, according to a law of physics, gives up the most of its heat to the surroundings and is itself cooled. This cooling action is materially aided by the inrush of cool air through the nozzle *A*. The cooled water impinges upon the step cone and drops to the tank below. In this dropping process, it is further cooled by the ascending currents of cold air. *F* is the drain pipe through which the fluid returns to the cylinders and goes to work once again.

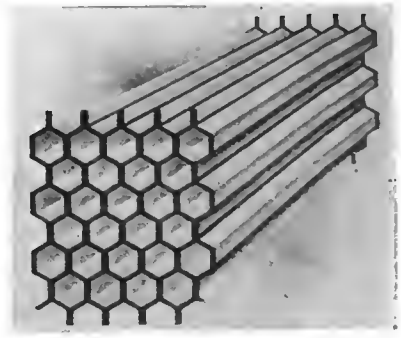

Fig. 11.—Section of a genuine honeycomb radiator.

Radiator Small Enough to Go on Dashboard.—The makers of this contrivance placed it on the dashboard rather than in front and made it very small. In size, three of these—the number necessary to cool a 30-horsepower engine—take up approximately the same space as a three-feed lubricator, viz., 6 inches long, 5 inches high, and 2 inches deep. A single addition to the usual outfit is necessary in the shape of a small tank holding a gallon, to care for the losses by evaporation at the nozzle.

Another novelty, apparently of equal merit, was brought out at the same time. It is shown in place on the dashboard of a large truck in Fig. 13. The line of reasoning which would apply here is that if the device was proven successful on a motor truck, where the radiator requirements are very severe, it could not help but be eminently satisfactory on a touring car. On a truck, the engine must run fast while the vehicle runs slow. The former means a great deal of heat to be dissipated. The latter, on the other hand, means very little air for cooling purposes. The combination expresses the necessity for excessive size, unusual efficiency or a combination of the two. In the two last cases, the device would be applicable for pleasure car use, but never with the former.

The principle and construction are both very simple. As Fig. 14 shows, there are two headers, one at the top where the water enters, and one at the bottom for the outflow. Connecting the two are a series of small diameter copper tubes arranged in semicircular form. This gives the outfit its cylindrical shape, and leaves the central portion for the fan. By making the external diameter large and restricting the number of tubes, the interior space is left large. This allows of the use of a very big diameter fan, which is not the case with the ordinary arrangement. By having such a large fan, and by rotating it at a high speed in the heart of the radiator, so to speak, a high efficiency is obtained. For touring practice, the diam-

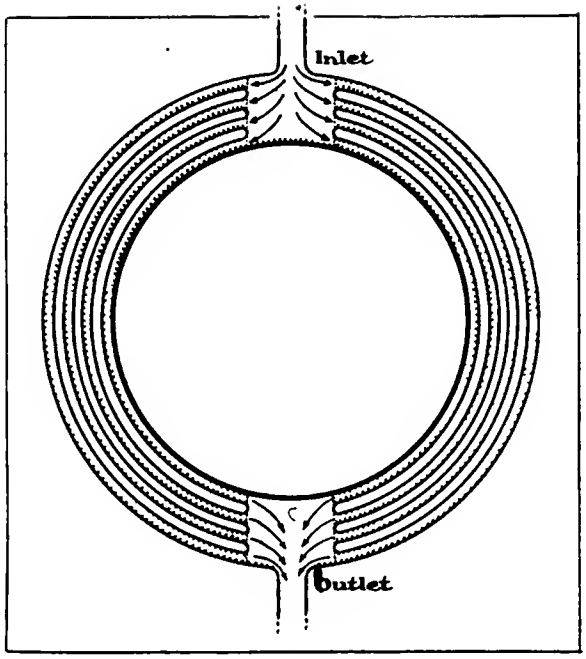

Fig. 14.—Illustrating a new principle.

eter would be smaller than the one shown, but the depth could be greater because of saving the space taken up by the fan.

Convection or Radiation, Which Is Most Important?—In discussing the efficiency of radiators or any other cooling medium, the qualities of radiation and conduction enter. To define these, radiation of heat is that action which takes place between bodies at measurable distances apart and follows the laws for the radiation of light. Conduction is the transfer of heat between bodies or parts of bodies which touch each other. Internal conduction takes place between the parts of one continuous body and external conduction through the surface of contact of a pair of bodies. Convection means the transfer and diffusion of the heat in a fluid mass by means of the motion of the particles. The latter is properly called internal conduction.

Relative ability of any body or substance to radiate and to conduct heat varies. Heat rays proceed in straight lines, and the intensity of those radiated from any one source varies inversely as the square of their distance from the source. The rate at which a hotter body radiates heat depends upon the state of the surfaces of the bodies as well as on their temperatures. The rate of radiation and of absorption are increased by darkness and roughness of the surfaces and the contrary also holds true, diminished by smoothness and polish. The quantity of heat radiated is also a measure of its heat-absorbing power.

The rate of heat radiation of various substances has been measured, and according to one well-known authority is:

Lampblack and water	1,000
Ordinary glass	900
Silver leaf and glass	270
Cast iron, brightly polished	260
Wrought iron, brightly polished	230
Steel, polished	170
Tin	150
Varnished copper	140
Cast brass, polished	110
Brass, brightly polished	70
Hammered copper	70
Plated gold	50
Gold on polished steel	30
Silver polished bright	30

Tests Show Increased Efficiency for Dry Surfaces.—On the subject of the conditions of the surfaces, a series of tests to show the effect of differences were made, using cast-iron in the form of a cube. These are of interest, and are given below:

Surface.	Oiled.	Dry.
Rough	100	100
Planed	60	32
Drawfiled	49	20
Polished	45	18

From which it appears that the oiling of smoothly polished castings more than doubles the loss of heat by radiation, while it does not affect rough castings, and finished ones only moderately.

The table of relative heat-conducting power of the metals tells a far different story, for here the metal which was low before is high. For the lesson it teaches, these values are given below:

Silver	1,000
Gold	981
Cast copper	811
Cast copper with .25% arsenic	771
Same with .5% arsenic	669
Same with 1% arsenic	570
Wrought iron	436
Tin	422
Steel	397
Cast iron	359

Now while these are pertinent to the subject and very interesting, they do not apply directly, for the desired quantity in any comparison of cooling is not an abstract one, but an absolute, definite entity. So one more table is given of the amounts of heat radiated by different substances.

Heat Units Radiated per Hour per Square Foot of Surface for 1 Deg. Fahr. Excess in Temperature:

Polished copper	.0327
Polished tin	.0440
Polished brass	.0491
Polished sheet iron	.0920
Sheet iron	.5662
Glass	.5948
Cast iron, new	.6480
Cast and sheet iron, rusted	.6868

Relative Value of Detached and Integral Fins.—While on the question of efficiency it will be well to call attention to one very practical deduction which may be made from the above tables, viz.: that a detached fin on a tubular cooler is not the equal of an integral fin. This is seen in the first and third tables. A detached fin would transfer heat by radiation, while an integral one would dispose of it by conduction. Taking any material at random thus, for tin, the radiating power is only 150-1000 of the best medium, while the conducting ability which would be characteristic of the integral tin fin is 422-1000 of the best. A tin fin on a copper tube is not the equal of a copper fin on a copper tube, even if both be soldered.

(To be continued.)

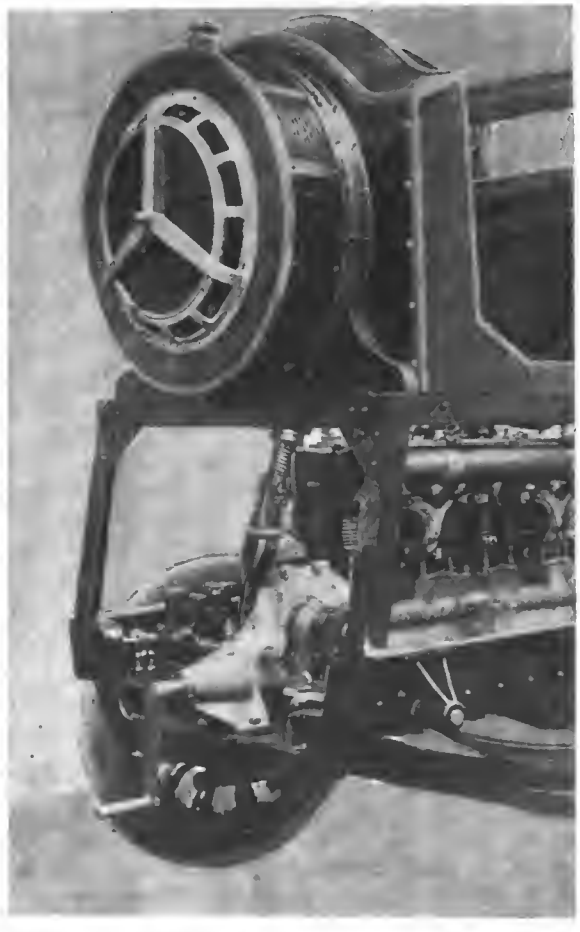

Fig. 13.—Novel radiator in place on a truck.

Self Starting Devices Attract Much Attention

TIME was when a motor that would start in a majority of crankings was something of a wonder. So far has the industry progressed, however, that to-day no one thinks a motor really good unless it will start on the first turn of the crank nearly always, and on the spark about half of the time. From a necessity, cranking is now considered by many as drudgery, so that efficient and reliable self-starting devices are in big demand.

There are not many of these on the market at present, but from all indications the coming and future years will see a gradually increasing number. Manufacturers who have fitted them in the past, even if they desired to discontinue, could not do so now on account of outside pressure. Similarly many makers who have not fitted them in the past are now working on various devices of this nature, in the desire to secure the necessary reliability before giving their stamp of approval.

Speaking broadly, there are two classes of starting devices, under one of which heads all starters come, as a matter of the basic principle and regardless of the details or the manner of working them out in practice.

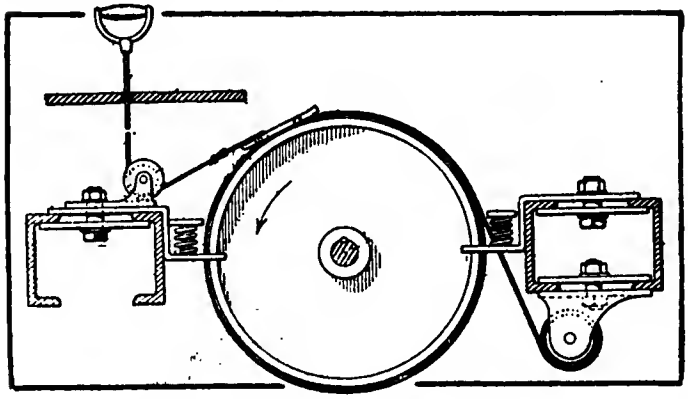

Fig. 1.—Strap used for starting purposes.

These are the mechanical or spring actuated and the compressed fluid actuated devices. In the first class properly belongs any mechanical contrivance by the use of which the driver of the car does not have to "wind up" the motor by means of a rotating lever directly attached to the engine, and, therefore, liable to a "back kick," which is the real objection to the cranking of the engine. This class includes such devices as the coil spring, wound up by the running of the engine after having been once started by hand. This is wound up tight and then the engine automatically cuts itself out, leaving the spring tense. To use, the spring tension is suddenly relieved by a suitable device and then it tends to unwind. This process results in a rotary motion which is utilized to turn the engine over.

Strap Starting Devices Look Very Simple.—In this class also belong that type of starters in which a strap is pulled upwards or sideways, this motion rotating the flywheel or other suitable drum. A spring returns the strap to place, so that it may be used over and over with no appreciable interval. In case the engine backfires or tries to rotate backwards, the strap simply slips on the drum or is pulled out of the operator's hand, with no attendant danger. Fig. 1 shows a commercial form of this type in which the strap is plainly seen. On the right is the drum upon which the strap is normally wound and held by means of a spring. The band or strap is normally held away from the drum by the two clips and springs, one on each side, but, when force is exerted upon it to turn the engine over, these allow the band to take hold. In this way there are no friction losses from the dragging of the band when it is not in use. The angle of contact is very large, being nearly 450 degrees, so that a small coefficient of friction (such as this device would have) is sufficient to do the work.

This principle is utilized in another starter, which has a side lever in place of the handle, the remainder of the parts being the same. Another one of the mechanical starters uses the side lever, but for the actuating means has a modification of the worm and gear. A deep spiral groove is turned in the prolongation of the shaft and a pair of dogs set into this. The latter are constrained to move in a straight line, so that only the shaft rotates. By operating the hand lever the other lever carrying the dogs is moved, and through the medium of the spiral groove turns the shaft around, the total motion depending upon the length of the spiral and the amount of the lever motion. It may, however, be such as to afford three turns of the shaft, which usually are sufficient for starting purposes. A jaw clutch prevents the rotating of the engine from being retroactive, that is, from working the starting device in the opposite direction.

Very similar to this is the form in which a rack and gear are employed, the latter arranged on the crankshaft with a clutch and the former contacting with it. Motion of the hand lever draws the rack across the car, thus rotating the shaft, and with it the engine. Still other mechanical starters have been brought out and, in some cases, successfully used, but in the main these follow along the lines of some of the above-described contrivances.

Fluid Pressure Systems Are More Popular.—Owing to the fact that all of these require more or less physical exertion, the difference between them and the ordinary cranking being the linear motion instead of circular, and the elimination of all danger, the use of a fluid pressure system in which there is neither work nor danger is more desirable and would be more popular. After cranking over a big motor the notion of pressing a button to start is particularly attractive.

Nearly all of these use the air, but some employ the exhaust gases. The advantage in so doing lies in the elimination of the compressor and the attendant mechanism to drive, connect and disconnect it. As well as making for simplicity, this saves weight, and the elimination of extra parts allows the driver more peace of mind. All this is said with the proviso that the arrangement works and works at the desired time, without which it is useless. The doubt here expressed is a large item, and has proved the downfall of many an apparently good mechanism.

The system just spoken of may take either one of two forms, viz.: the actual exhaust waste gases may be drawn off from the motor, stored in a tank, and used as a source of energy; or the mixture may be taken during the compression stroke, just before ignition, so that the starting fluid is a combustible mixture and differs in the strict definition from carbureted gas only in heing under great pressure.

The complaint made against using the exhaust is that the starting gases so weaken and impair the mixture from the carbureter that a considerable number of turns are necessary to start the machine. This in turn means a very large gas storage tank, which adds materially to the weight of the car. The exhaust pressure, in a well designed engine running under normal conditions, seldom exceeds 35 pounds, so that a high pressure may not be obtained from this source.

Any Pressure Possible with Outside Compression.—The method of utilizing the compressed gases has the same detri-

mental feature, but not in so marked a degree, in that *any* pressure is impossible. However, a very high pressure in comparison with the other method is obtainable. The compression usually runs from 70 pounds upward, and it has been known to be as high as 110 pounds, so this would give good, if not maximum results.

With an outside and independent compressor any desired tank pressure can be obtained, and, as a matter of fact, the majority of these systems do use it higher than any of the figures thus far given. In the Saurer system 225 pounds is maintained in the reservoir at all times, while the Renault method utilizes 250 pounds. Others use other pressures, but they are above 200.

As usually constituted, a fluid pressure system consists of a source of pressure or compressor, a storage tank, a distributing valve and a lever, button or other operating means. In use, the engine must be started by hand in the first instance. This creates a source of power, whether it be exhaust gas, compressed gas or air from a compressor driven from the crankshaft or camshaft.

Fig. 2 shows the essentials of a system in which the air-cooled compressor is driven off of the main driving shaft just ahead of the gearcase. The hand lever shown on the dashboard, when forward in the position marked I, throws the compressor clutch in, and it then charges the storage tank. The valve to the latter is set at 225 pounds, and when that pressure is reached the clutch is automatically cut out.

A Simple Touch on a Lever Starts the Engine.—When it is desired to start the car the lever, shown in larger size and more detail in Fig. 3, is pulled backwards as to position III, the compressed air from the tank flows up through the governing valve and thence to the distributor. The latter is situated high up between cylinders 2 and 3, and is driven by miter bevel gears from the crankshaft, so as to have the same speed of rotation as the latter. This consists of a revolving sleeve in which are cut ports, one for each cylinder. As the sleeve turns (with the crankshaft) these ports register in turn and in the proper firing order, with passages which connect to the individual cylinders. The air under pressure is admitted by the governing valve, on the dash previously spoken of, to the interior of this sleeve, and thence to the proper cylinder.

As shown in Fig. 4, this is open to cylinder number 2, and in this situation the air will pass into that one and drive the piston down. This must necessarily turn the crankshaft around, and with it the distributing valve, which thus registers with the cylinder next in the firing order, number 4, or whatever it may be. From this it is plain that the tank will continue to feed air to the cylinders until all of the supply has been exhausted or the engine has been started.

A feature prominent in another system may be mentioned briefly. This is essentially the same as the one just described, but the control of the compressor differs in that the air-suction valve has a flexible diaphragm which is in contact with the tank, or rather to which the compressed air has access. As the pressure rises

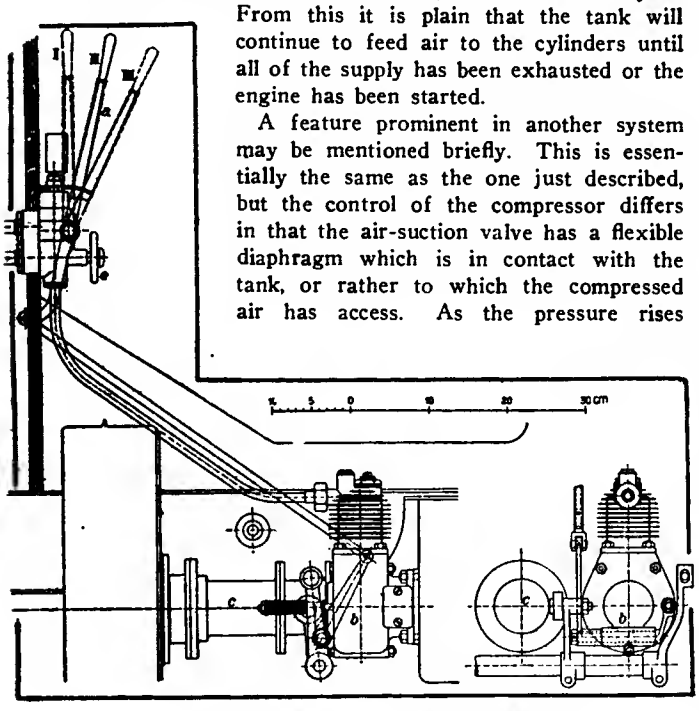

Fig. 2.—Essentials of a successful air starter.

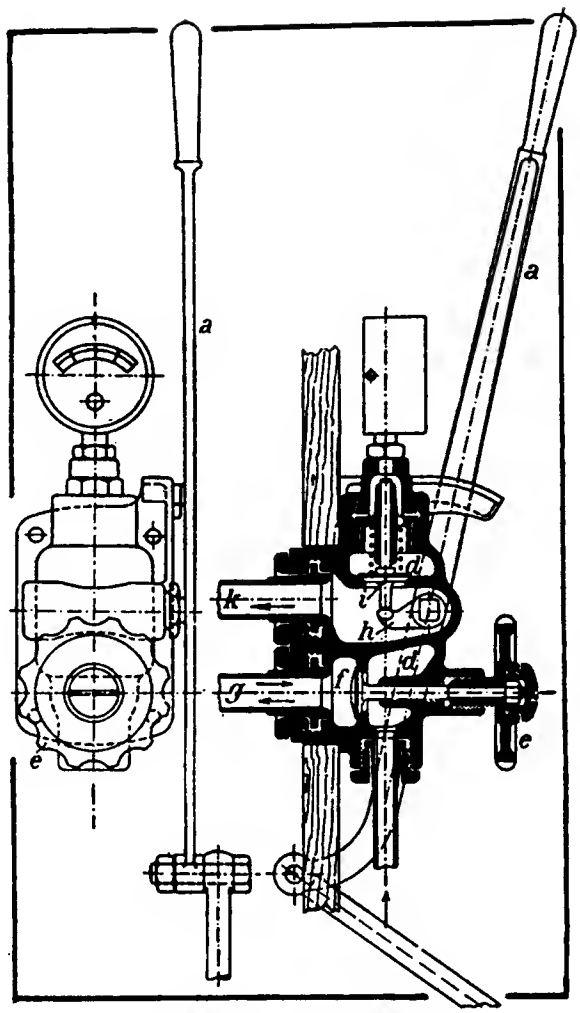

Fig. 3.—Details of the dashboard control.

this distends until, at the predetermined maximum, it holds the air inlet open, thus preventing compression and consuming no power. Of course, as the pressure falls off from leakage or the use of air the diaphragm changes its position to correspond, until at a certain fixed minimum pressure the suction valve will be allowed to close on the compression stroke, and thus the tank will be automatically replenished.

Pressure Useful in Other Ways.—Having a large tank of highly compressed air handy is useful in many other ways. For instance, for inflating tires, the autoist would take a chance on starting with less air and utilize a part of the tankful to inflate his tires. In many other ways this would be useful, but with exhaust gases in the tank most drivers would hesitate to use this source of pressure.

There are other systems which while using a part of the apparatus above described, do not use all of it, and consequently differ somewhat in their action. One that was given publicity recently is based on the assumption that when the spark and throttle are correctly manipulated just before stopping all of the cylinders but one will contain an explosive mixture. Granting that this is so, all that is necessary is a spark in the cylinder in which the piston is in the proper position for firing. This spark is effected by disengaging the driving gear and throwing the magneto armature around to a contact, the arrangement being such that on starting, the magneto gear drops back into its proper position and ignition proceeds as usual.

Latest Device Combines Electric and Pressure Methods.—The most recent starting device is in the nature of a combination of the stored pressure and the electrically operated devices. This is an American product, made in the Middle West, and very recently placed on the market, after two years of experimentation and successful tests.

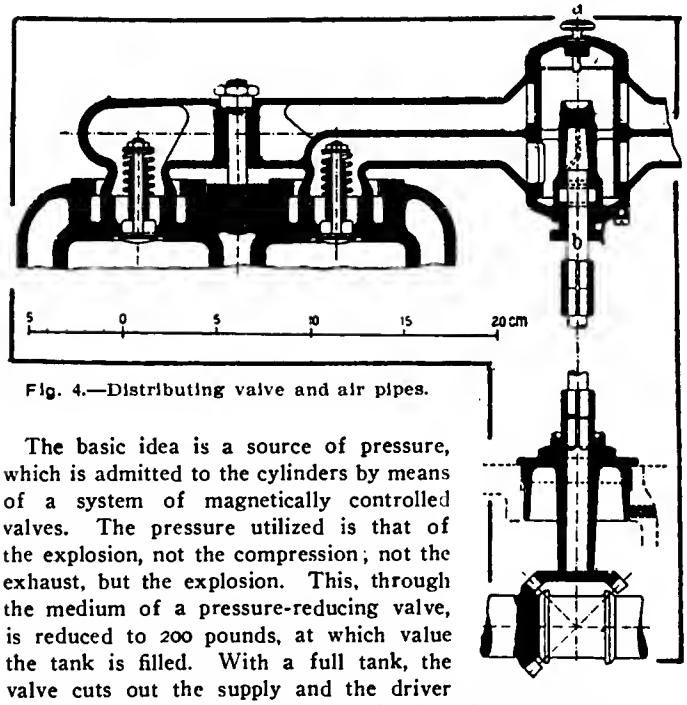

Fig. 4.—Distributing valve and air pipes.

The basic idea is a source of pressure, which is admitted to the cylinders by means of a system of magnetically controlled valves. The pressure utilized is that of the explosion, not the compression; not the exhaust, but the explosion. This, through the medium of a pressure-reducing valve, is reduced to 200 pounds, at which value the tank is filled. With a full tank, the valve cuts out the supply and the driver can then close off the valve communicating with the cylinders.

For starting, this fluid pressure is admitted to the cylinder through the medium of the distributing valves, which are placed on top of the engine as shown in Fig. 5, this being a view of the apparatus applied to an automobile engine. These valves are operated by means of an electric current, diverted from the regular ignition source, the only necessity being a direct current. This current is led through an ordinary timer and from there to the distributing valves in the cylinder heads. Thus it is that the valves are opened in proper rotation, each at the top of the piston stroke, which, while it is the correct position for the igniting spark in ordinary running, is also the correct position for the starting effort. So through the medium of the magnetically controlled valves the pressure is introduced to the proper cylinder at the proper moment. In the figure, *A A* are the magnetically controlled valves, to which the wires *D D* lead. *B* is the supply pipe from the storage tank. The shutoff valves are operated by a hand lever on the dashboard. *C* shows these, and just above them may be seen the operating rod. If a car has a double ignition system, the battery-timer system may be used for the starting by putting the starting switch in that circuit. Then by throwing the ignition switch to the battery and timer, and the starting switch to the starting position, the gas is admitted to the proper cylinder, the engine is started, and the ignition switch may be thrown over to the running position, whatever that may be, and the starting switch may be cut out.

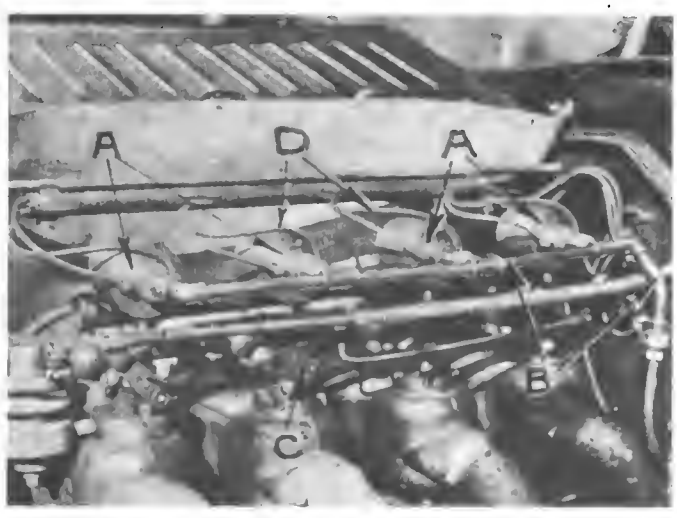

Fig. 5.—Combination system applied to an engine.

This describes briefly the important features and method of operation of the principal forms of self-starting devices now in use. From a survey of these it is a safe prediction that from this time on each succeeding year will see more and more self-starters fitted to cars and working successfully.

CLEVELAND'S TRADE BAROMETER O. K.

CLEVELAND, March 29.—Things are "looking up" in the trade in this city, and from present indications 1909 will be the finest selling season ever enjoyed by the trade in northern Ohio. Every retailer, no matter whether he is selling cars or accessories, is doing good business, while the factories are all pushed to their limit.

The trade barometer in this city is steadily on the upward trend. No clearer indication of this is to be found than in the altered appearance of Cleveland's "auto row." The empty stores are gone, and in their places are appearing new concerns, already doing a good business. Enlargements and alterations are under way, while many companies heretofore located further down town are moving onto the avenue. Among the latter are the Pennsylvania Rubber & Supply Co., now located at 1843-45 Euclid, and the D. E. Foote Rubber Co., whose new address is 1837 Euclid. The new Firestone Tire & Rubber Co. is about ready to open its doors at 1930, while the Hammer & Hull Co. have located at 1841, the latter concern doing a general plating and repair business, devoted chiefly to fenders, pans and other metal parts.

One of the new concerns to exploit a car is the Avenue Motor Car Co., 1806 Euclid, agents for the Oakland. The Weddel House garage has taken the agency for the Inter-State in addition to the Regal. A number of other machines are scheduled for an early appearance, it is said. But the best of all is found in the fact that good, solid business is being done, although the weather does not allow of suitable demonstrations.

MAXWELLS NEED MUCH RAW MATERIAL.

Few people realize the tremendous quantity of raw material used by a large automobile concern; nor is this material confined to metals and those materials ordinarily associated with automobiles. To give an idea of the size of this business, the Maxwell-Briscoe Motor Co. is soliciting bids on material for the building of 12,000 cars. Among the articles enumerated are 200 tons of aluminum castings and 150 tons of brass castings. The babbitt metal that goes into the bearings alone is in excess of 50 tons, while the brass tubing that is used so extensively in automobile construction figures up something like 126,000 feet, or approximately 25 miles. In other words, enough tubing will be used on Maxwell automobiles to extend from New York to Tarrytown. The rivets alone will weigh over 30 tons.

Nor are the bids confined to metals. For example, 13,000 hides will be used for upholstering and trimming. Materials for tops call for over 40,000 yards. Then there is the iron and steel, of course, the biggest factor, 1,000 tons of steel bars, 800 tons of malleable iron, and so it goes. In special steels which play such an important part in the building of an automobile, the bids call for 50 tons of chrome nickel steel and 50 tons of nickel steel.

Although various modifications have been agreed to by the German Government commission in discussion on the Motor Liability law, yet the resolution agreed to prohibiting racing on the road will come as a severe blow to the sport, should it be passed by the imperial diet. The spirit controlling the diet is on the whole not favorable to automobilism, and should this measure go through, it will mean a very scanty European program. This season would probably not witness any big road racing in the Fatherland.

Letters Interesting and Instructive

TO VAPORIZE POOR GASOLINE.

Editor THE AUTOMOBILE:

[1,810.]—Please advise me through "Letters Interesting and Instructive," why gasoline at 72 gravity is better than that of a lower gravity, say 64, and if there is any way of doctoring up poor quality or low gravity gasoline to a higher point of efficiency. G. A. J.

San Francisco.

The density, or, as you have called it, the gravity, of the fuel really measures the vaporizing ability. This may be stated otherwise by saying that if the fuel is heavy, the work of converting it into a gas will be more difficult and will require more oxygen. It may be supplied in the form of any substance known to be rich in that element, as, for instance, picric acid. While this will allow the use of a low grade fuel for equal results, or if used with ordinary fuel (72 degrees), will give superior results, its use should be discouraged, as the resultant mixture is highly explosive under all conditions. Also, the other constituents of the acid are left in the cylinder as a deposit and the liquid itself is very expensive.

You can help yourself with low-grade fuel by the use of pure oxygen as put up in tanks, feeding it to the carbureter in small quantities. Air, as you know, carries only 20 per cent. oxygen by volume, or 23 per cent. by weight, the rest being foreign matter as far as vaporizing the fuel is concerned. Why use this medium, when you can use a pure oxygen with no foreign matter and a consequently improved efficiency? All this, providing you are willing to pay the bill.

NEW AIR PROPELLER BRAKE.

Editor THE AUTOMOBILE:

[1,811.]—I wish to call your attention to the article that appears in "The Automobile" of March 18, page 469, entitled, "Features of new air propeller brake." If I understand this article right, the air propeller is driven by the roadwheels through the gearset and propeller shaft.

Further on is stated, "There is one other advantage to be taken into account in connection with brakes which receive their 'purchase' by way of opposition in the air, i.e., it does not matter at all if the wheels lose their tractive ability, since the fan brakes would still be in a position to work, regardless of the tractive ability of the road wheels. Indeed, the car, fitted out in this fashion, could be controlled even if the wheels might slip, so that the conventional brakes would fail to work, due to loss of traction on a grade."

Now, if the "fan" is driven from the rear wheels and these slip, does it seem reasonable to you that the "fan" should have any effect on the car? The way I understand that the "fan" is constructed, it is not its resistance to the air that has the desired braking effect on the car, but the resistance to the turning of the rear wheels caused by the power consumed in running the "fan." On the other hand, if the "fan" was driven by the power of the motor, the "fan" would not have any effect on the car at all, as far as I can see. In the latter case, the only effect that the "fan" would have on the car proper would be a tendency to turn the car in the opposite direction to that of the "fan" if it is of large capacity. In my experience of hilly driving, I have always found it most economical to use the engine as a brake, and I believe it just as effective as the "air propeller" referred to. The "fan" would also be a bad "dustmaker."

I also wish to answer letter No. 1,795 in the same issue regarding signals, I have used the following around here with good results; one blast for request to pass; two, for turning out or turning corner to the right; three, for turning out or turning corner to the left; two long and two short for road or street crossing. ARTHUR BEIJER.

Phillips, Wis.

To correct you on the subject of this new brake, it will be necessary to state that the article relative to it from our Paris correspondent was rather misleading, in that the driving mechanism was not fully explained. The fan brake is driven through the transmission and the lever controlling it allows the use with any speed provided in the gearbox. So it is plain that whether the wheels slip or not, the brake continues to work, providing the engine is running.

Now, as to the action of the propeller, it is so set as to tend to propel the car in a backward direction just as the reverse speed would. Descending a long hill, the force of gravity urges the car along at a considerable speed. In this case, the air brake lever is thrown into low speed and the power of the motor exerted against the downward tendency. If this were not sufficient, the second or higher speed would be thrown in, and the air brake rotated at a higher speed, with consequently greater retardation of the car. Ultimately, if necessary, the high speed can be used and the whole power of the motor applied to the purpose of braking. The device thus has an enormous advantage over the ordinary practice of shutting off the spark and using the compression strokes of the engine as a brake, in the ratio of the total maximum power to the comparatively small amount of power required to compress the charge.

In addition, the method of driving as you understood it will operate correctly. If the wheels slip, and the car momentarily accelerates, the extra speed turns the fan faster, which in turn increases the backward tendency, and thus offsets the slight gain in the forward direction. To sum the matter up, the engine turns the rear wheels and through them the fan. For the slope to increase this, it must increase the fan speed, which makes it necessary to increase the engine speed, which is apparently impossible.

STEEL TUBING FOR CYLINDERS.

Editor THE AUTOMOBILE:

[1,812.]—Will you please state in your valued paper if it be possible to use cold-drawn steel tubing in motor cylinders? WILLIAM HILLIARD.

Chicago, Ill.

Yes, steel tubing not only can be but has been used on some French racing motors. Its use necessitates an attached cylinder head and applied water jackets. The former is a construction which all designers do not favor. Another point is that while the action of cast-iron pistons at high temperatures rubbing on cast-iron cylinder walls is known, the same cannot be said for iron pistons on steel walls. The reverse of this, steel pistons in iron cylinders, has been tried and abandoned by several noted French firms.

This trouble is brought about by the difference in the two coefficients of expansion, the linear coefficient for cast iron being .00000556; for steel, .00000689. The cubical coefficient is three times this, or iron, .00001668; steel, .00002067. From this a piston which was just right for a four-inch cylinder at 70 degrees (.004 inch small), would be loose (.006 inch small) at 470. With larger cylinders and higher temperatures, it rises in proportion.

SHOULD FRONT WHEELS TOE IN?

Editor THE AUTOMOBILE:

[1,813.]—On page 464, March 18 issue, in the article on steering gears by Mr. Fay, appears the statement that "if one (front) wheel toes in and the other is parallel with the roadway it will be very difficult indeed to steer the car." Also the statement that each of the front wheels should be adjusted to toe in exactly the same amount.

Will Mr. Fay please state what direction the car will tend to follow under the condition first named above, and will he please explain in what respect this condition differs from that of an intentional deflection of one degree, or thereabouts, produced by the driver to alter the course of the car? Are we to suppose that the car will steer perfectly when running straight ahead with each front wheel toeing in one degree, but will become partially unsteerable as soon as the driver turns the steering wheel till one of the front wheels is "parallel with the roadway"? When it comes to that, what has the direction of the roadway to do with the matter at all?

The article on acetylene generators in your issue of March 25 is full of inaccuracies. Calcium carbide is not soluble in water; it is not deliquescent, and the color of the commercial article is not dark brown, but gray. Overheating is alluded to as a probable and important source of trouble, but nothing useful is said about its cause or how it may be avoided. A good generator will not overheat under any circumstances. The drawing of the "conventional type of generator" shows a water jacket, but nothing is said in the text regarding the utility or otherwise of this jacket. The statement is made that a generator will afford an ade-

quate supply of gas at the right pressure, "cool and free from soot, sand, tar, and steam," provided the generator is big enough for the work and if provision is made to "scrub, cool, and purify the gas as it is delivered into the piping system." This is simply rubbish. No automobile generator, within the writer's knowledge, contains any provision whatever for scrubbing the gas, nor any further provision for purifying it than the usual hair filter. A correctly designed generator does not need such provisions, and a poor one is not helped by them. Neither is it true that the size of the generator has anything to do with its ability to maintain the correct pressure on the gas line, except that in a small generator the water is more rapidly consumed and the pressure therefore falls faster than if the generator be of good size.

The statement that the water soon gets hot as a result of the heat generated by the "dissolving" of the carbide, is equally incorrect. The water gets slightly warm; no more.

The allusion to the "sludge" resulting from the action of the generator suggests that possibly the author's experience is limited to the generators in vogue five years ago, or to the cheap brass cans which are "thrown in" by the makers of the cheap class of cars, and (usually) thrown out by the purchaser after one or two attempts to make them work. In a good modern generator no sludge is formed, the lime taking the form of a dry powder.

In warning the reader against slipshod piping, the author forgot to state that a trap should be provided at the lowest point of the piping system which should hold two or three teaspoonfuls of water without interfering with the flow of gas. Such a trap rarely needs to be drained, as the condensed moisture evaporates between runs.

HERBERT L. TOWLE.

New York City.

In the Fay article in relation to steering, it is clearly indicated that the front road wheels should be set to toe in slightly, rather than to be set indifferently. In another part of the same article it was pointed out that instability begins when a car is diverted out of its straight course. Any statement in an article should be weighed in the presence of other statements bearing on the subject and intended to amplify.

Account must be taken of acetylene generators of a class that do not come up to Mr. Towle's standard. If a generator is so good that it will not give trouble, the possessor will be wasting his time on the article to which reference is made.

TIRE CAPACITY EXPLAINED.

Editor THE AUTOMOBILE:

[1,814.]—Will you kindly give me the rule or formula by which the carrying capacity of an automobile tire is determined? I have seen tables published from time to time, but am unable to arrive at a hard and fast rule for calculating weights from sizes. Take, for example, three tires: 36 by 3 1-2, 32 by 3 1-2, and 30 by 3 1-2. In actual experience, the last size will outwear the other two, but in running over small depressions, the larger tire is easier on the passengers.

I believe it would be interesting to your readers to have a full discussion of this subject, as the wearing properties may be vastly different from the weight sustaining powers. For instance, a 36 by 3 1-2 tire might sustain more weight while standing idle than a 30 by 3 1-2, yet the smaller diameter would outwear it.

CHARLES V. CRITCHFIELD.

Mt. Vernon, O.

There are two questions to be considered: The ability of the tire to withstand pressure from within, and the weight-carrying ability when properly inflated. The wearing qualities vary with different makes, with different sizes, and with different diameters. This, too, being a question of relative ability cannot be discussed in these columns.

The fabric used in tires varies, but in general good fabric will stand a breaking strain of about 350 pounds per square inch. In a tire having six plies, there is a strength of six times this, or 2,100 pounds per square inch. From this it is apparent that there is very little danger from any ordinary pressure.

The weight on a tire is carried not by the tire itself, but by the air pressure within, the tire simply acting as an envelope to retain this air where it is wanted. If there is not sufficient air pressure to bear the weight, the tire must suffer. Tire manufacturers seem to agree very closely on the carrying capacity for the sizes herewith mentioned:

Size.	Carrying Capacity.
30 x 3½	450 pounds 500 pounds 450 (front) 550 (rear)
32 x 3½	550 pounds 600 pounds 500 (front) 625 (rear)
36 x 3½	600 pounds 600 pounds 600 (front) 750 (rear)

These figures are from three firms, differing as to location, style of tire made, and quality of the same.

HINTS FOR WORTHY CONTESTS.

Editor THE AUTOMOBILE:

[1,815.]—Having just read an article in the March 18 issue entitled, "The More the Haste, the Less the Speed," I would like to make a few suggestions along the same line. We will all agree with the writer of the article that in road races and hill climbs, where speed is the main object, the direct benefit to the buying public is very small; still, at the same time, we must realize that the strength and endurance of a car is tested under these circumstances more than under any other. Therefore, it is a positive fact that the designer is greatly benefited by long, high-speed races and hill climbs, and if the manufacturer will use the material and design in his commercial car that he does in his racer, granting, of course, he makes minor changes to conform to the two distinct purposes involved, the purchaser can rest assured that the car he builds will be one of the best.

Speed contests serve their useful purpose and give a sporting interest to the business; so let them continue, but at the same time give the prospective buyer a contest that will be of special benefit to him. The endurance contest is all right, but the bystander cannot see it clear through. He can see one car, then another pass, but unless he is very much interested he never knows who won, or why. He wants a contest wherein he can see the start and finish and knows who wins, finally.

The coasting contest suggested is along the proper line, but too easily imposed upon. We all remember the old coasting contest of bicycle days when the machines weighed several times what a standard stock machine would be permitted to weigh, bearings were adjusted so loose that they would not have stood up to one hour's hard work, chains were left loose, and in many cases dropped off the sprockets while coasting. All this was done to eliminate friction, and the same things and many more would be done to an automobile under the rules suggested. If the clutch was disengaged, wherein would the motor, the vital part of a car, and its attachments be tested? If the clutch were engaged, there would be a hundred ways to beat around the rules, so that the contest would demonstrate nothing.

One of the most desirable things in an automobile is a flexible motor and power at motor speed. To bring out these points, I would suggest a hill climb run as follows:

Let each car climb the hill for speed on high gear; then let each car climb the hill on high gear at slow speed. Make it necessary that cars start on high and keep the clutch in after it is once set, the touching of clutch, pedal, or lever being cause for disqualification. The result of the contest would be determined by proportioning of the results of the two climbs.

Another method would be to have the time of the cars taken at a half-way mark; also at the top of the grade under the following conditions: Compel the cars to start on high gear at the foot of the grade and proceed as slow as possible to the half-way mark, from there on make it a speed contest, but require that the high speed be used all the way. The final showing would be computed on the times shown at both places.

In working up a formula for either of these contests, the writer would favor one giving the advantage to the car that made the best showing at slow speed, because we all know that the motor that is so built that we can drive in deep mud or gravel, or on a grade for a long distance on high gear without having to race through at a dangerous pace, is to be preferred to the one that must use a lower gear or high car speed to get engine speed in order to obtain power. Therefore, give the motor that can develop power at slow speed a chance to show its worth. But it must have a reasonable amount of speed; therefore make it work at both. In fact, in order to prevent exceptionally low gear ratios on high, it might be well to compel the cars to compete in short speed trials on the level and use this time in the final results. Such a contest would not only test the cars in every respect, but also the skill of the driver and be beneficial to all.

Peru, Ind. H. M. CONROW.

VALUE OF COASTING TEST.

Editor THE AUTOMOBILE:

[1,816.]—Your March 18 issue with the article, "The More the Haste, the Less the Speed," by C. E. Duryea, if more than casually read suggests many pertinent thoughts. His article contains some of the ideas in my letter, published a year ago.

It occurs to me now that a "coasting test" might be further enhanced by the following: Take the speed of the car over the last 100 feet by approved automatic methods and compare it with the reading of the speedometer taken by an official observer. When the car crosses the finish wire of the speed test, automatically fire a gun, and measure the time and distance required by the driver to bring his car to a stop.

Comparisons are often odious, and might sometimes be so in tests like these.

Chicago. Dr. M. A. MARTIN.

Spring's Advent Stimulates Club Activity

LONG ISLANDERS INITIATE NEW CLUB HOUSE.

BROOKLYN, March 29.—Situated literally "at the gateway of Long Island," at the entrance to Prospect Park and the Eastern Parkway, the new club house of the Long Island Automobile Club was opened officially on last Friday evening, with a "biggest" smoker and vaudeville entertainment. Fully five hundred persons attended, members bringing their friends, the new rooms inspected, and the varied programme thoroughly enjoyed.

For several years the club has been located at 360 Cumberland street, but recently the new home was secured at 920-922 Union street, a well equipped garage being taken, the four floors and basement renovated and rearranged so that the second floor could be used for the club members, while the other three floors and the basement are used for storing and caring for the machines. This means of combining the two features of the club has given a great deal of satisfaction, and already the garage space is pretty well taken. Cars have been stored in the building for nearly a month but the club rooms have just been finished.

The second floor is spacious enough to be divided into four parts, a billiard and pool room, a reading and writing room, a dining room and offices. They are all separated by portable partitions, and when entertainments are scheduled, these are removed so that the whole floor can be used, and stage is wheeled into position. The color scheme is green and white, with a choice selection of automobiling pictures on the walls, cabinets for trophies included in the furniture, and nothing left undone to provide for the comfort and pleasure of the members. The kitchen installed is large enough to handle a banquet, and regular dinners will be served from it.

Once a month, or nearly so, a vaudeville entertainment is given, under the direction of Edward Melvin, who is chairman of the house committee. President Frank G. Webb opened the club rooms with an address of welcome. The other officers are William P. Schimpf, vice-president; Charles T. Cuff, treasurer; Herbert G. Andrews, secretary. A ladies' night is set for April 16.

WILKES-BARRE GETS NATIONAL HILL CLIMB.

WILKES-BARRE, PA., March 29.—That the annual hill climbing contest of the Wilkes-Barre Automobile Club on the Giant's Despair Mountain will be an event of national character has been confirmed through the receipt of the sanction for the national hill climb from Frank B. Hower, chairman of the A. A. A. Contest Board. With this in the hands of President George F. Lee, of the local club, the enthusiastic autoists of this city will at once begin the preparations for the contest, which will undoubtedly be one of the most important events in the automobile world.

As May 30 comes this year on a Sunday, it has been decided to hold the contest on Monday, May 31, and it is expected that not only the usual quota of powerful cars and drivers will be present, but many new ones, and perhaps some foreign cracks, Fred J. Wagner, the famous A. A. A. starter, who has officiated in that capacity with great success here before, will have that position this year, and will be given more authority and more of the preparatory work than heretofore.

GRAND RAPIDS CLUB CHOOSES NEW HOME.

GRAND RAPIDS, MICH., March 29.—The members of the Grand Rapids Automobile Club unanimously decided at their meeting recently on Cascade for their new clubhouse. This is the same house used two years ago, but a new road leading from the Thornapple River to the house has been built, and the house will be completely refurnished. It will be ready for use May 1.

HARRISBURG CLUB MAY HAVE TIRE TEST.

HARRISBURG, PA., March 29.—In response to the frequent proposal of combining a tire contest with an endurance run, the Motor Club of Harrisburg is considering having this feature in connection with its annual contest next May. Secretary W. R. Douglass has taken up the matter of rules with some manufactures, and George M. Stadelman, secreary of the Goodyear Rubber & Tire Company, has suggested the following:

All tires used in the contest should be purchased on the open market, which prevents the use of special tires made for the purpose, and which are not sold regularly to the trade.

Each tire manufacturer should have the right to designate the particular style of tire he manufactures to be used in the contest.

[By way of explanation, we wish to state that this company makes two forms of tires: detachable with straight sides, and clincher with beaded sides. We make the former because we believe it to be the most practical, durable and trouble-proof design. We make the latter because there is a demand for a tire to fit regular clincher rims, on which our detachable form of tire cannot be used. For this reason, it would be unfair to compel this company to enter clincher tires in the contest, when we are positive that our detachable form of tire is better suited for the purpose, and is the one that we are urging automobilists to buy.]

All time lost for stops occasioned by tires should be penalized a certain number of points for delay occasioned by punctures; a heavier penalty occasioned by blow-outs; and a still heavier penalty for loss of time occasioned by tires blowing off the rim.

We would allow each car three tires for rear wheels, and three tires for the front wheels, which would provide one spare for each wheel without penalizing for anything but time lost; but should a car have to use the seventh casing, or more, a very heavy penalty should be inflicted for each additional casing in addition to time lost for charging.

There should be official observers to check the tire losses in a similar manner to the way each car's losses are checked. The tire companies competing should have representatives in the races, but not on cars equipped with their own tires.

A duplicate set of rules has been sent by Mr. Stadelman to the Contest Board of the A. A. A., suggesting a similar tire contest for the Glidden Tour.

WHAT ONE CLUB HAS DONE IN ITS VICINITY.

PHILADELPHIA, March 29.—Chairman W. O. Griffith, of the routes, maps and signs committee of the Automobile Club of Philadelphia, has outlined a comprehensive campaign for the coming year. Four sections of the club's map scheme are under way, and will probably be published in the course of a year.

The new club route book of 213 pages contains 180 pages devoted to new routes and maps. An idea of the enormous amount of work done by this committee last year may be had from the annual report of the board of governors, which showed a total of nearly 1,100 signs of various classes placed in position, including mileage, direction and warning signs. This means that no less than seven main through routes and about a score of minor routes out of this city have been clearly and thoroughly marked at all crossroads and forks, dangerous hills, sharp turns, and with warnings where the authorities are particularly severe. The end of the coming year will see this result multiplied by two, if Chairman Griffith can secure money to carry on the work.

GERMANTOWN'S CLUB AFTER OFFENDERS.

PHILADELPHIA, March 29.—In an effort to put a stop to the numerous gross violations of the speed ordinances in this city and suburbs, the committee on Automobile affairs of the Automobile Club of Germantown is urging members of the club to inform Chairman C. H. Wheeler immediately of all such violations, giving the number of the car and the particulars.

NOW BALTIMORE PLANS AN ENDURANCE RUN.

BALTIMORE, March 29.—These are busy days for the members of the Automobile Club of Maryland. They are now making preparations for holding a tour, or efficiency contest during the month of May, and Secretary Frank Darling has already prepared a tentative plan and route. He proposes that the course be from this city to Ridgeville, and thence to Frederick, a distance of 48 miles, taking the cars over roads that at their best are only fair. On the return trip, at Eccelston station, there is an exceedingly steep hill, and Mr. Darling's plans call for timing the cars on the mile and a half climb.

The cars on the outbound trip would pass through Lewistown, Catoctin, Thurmont, Emmitsburg and Gettysburg, a distance of 33 miles from Frederick. The road from Emmitsburg to Gettysburg is rather rough, and would be a good test for the cars. Returning the cars would go through Littlestown, Westminster and via the Valley road, which comprises about 35 miles. This would make the entire distance of travel about 115 miles, which the cars would be expected to make within seven or eight hours. The rules specify that all hoods shall be sealed and the cars placed in a garage, under the care of the contest committee, until the machines have been examined for loose parts and other mishaps that might occur in consequence of the run.

QUAKER CITY M. C. WANTS A TRACK RACE.

PHILADELPHIA, March 29.—The most surprising bit of news from the various local clubs' headquarters the past week was the announcement by the Quaker City Motor Club that a 24-hour track race would be run off under its auspices—probably at Point Breeze track—on June 11 and 12. In the light of the A. A. A.'s announced determination to discourage recing on mile circular tracks, this looked very much like open rebellion or a decidedly marked change of opinion on the part of the National Contest Board. Certainly the Quakers appear to be cocksure of securing the necessary sanction, and are already at work on the preliminaries of the race, for which it is claimed a sufficient number of entries had previously been promised to insure its success from that standpoint.

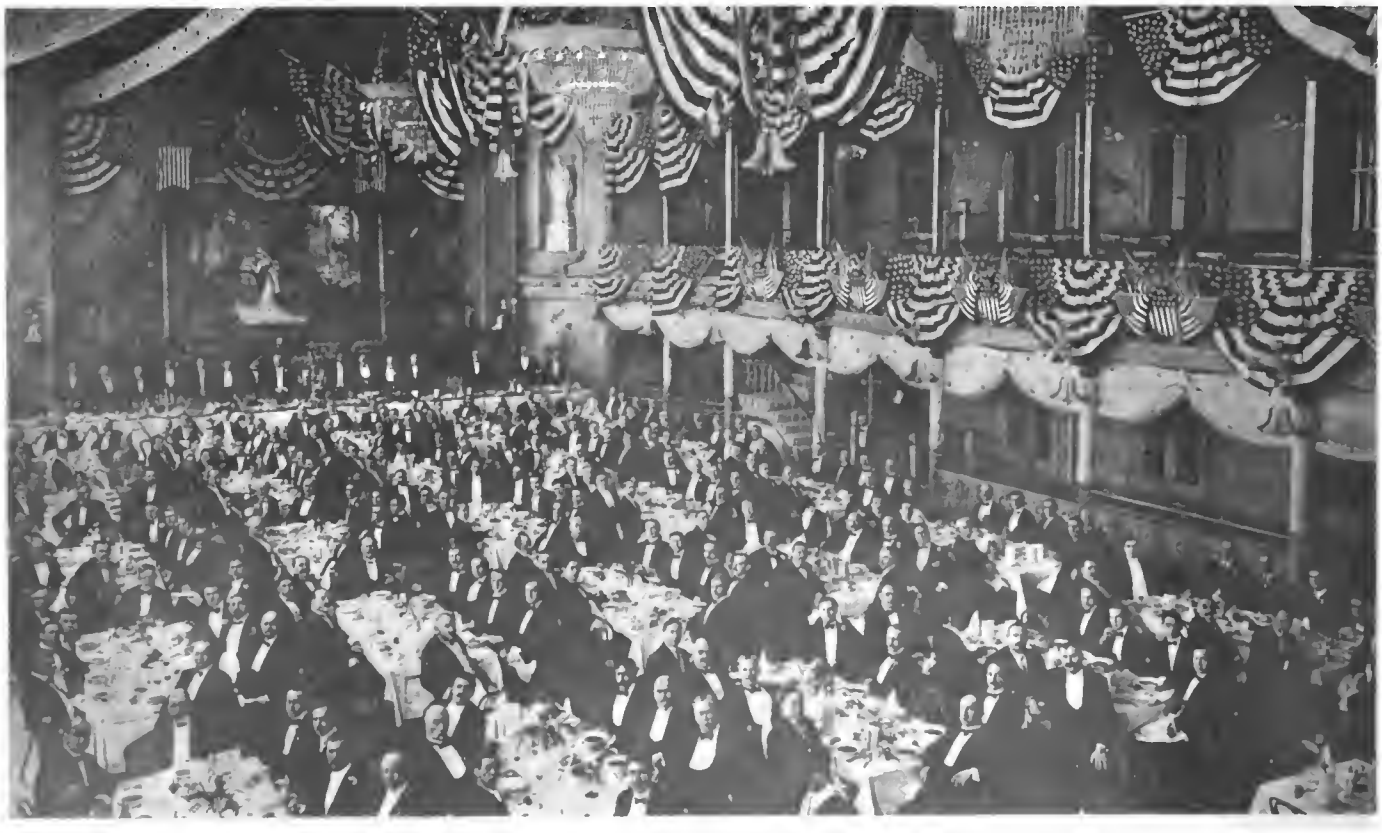
NEW JERSEY RUN FOR AMATEURS ONLY.

NEWARK, N. J., March 29.—For amateur drivers only, members of the club who are not connected with the trade, the New Jersey Automobile and Motor Club, is arranging to hold its third annual endurance contest over a ninety-five mile circuit, with two laps, giving a total distance of 190 miles, on May, 22, if plans as already outlined prove thoroughly feasible. At this time of the year when the trade members of the club are particularly busy, it has been decided to put them all on an equal footing, by making the affair for private owners.

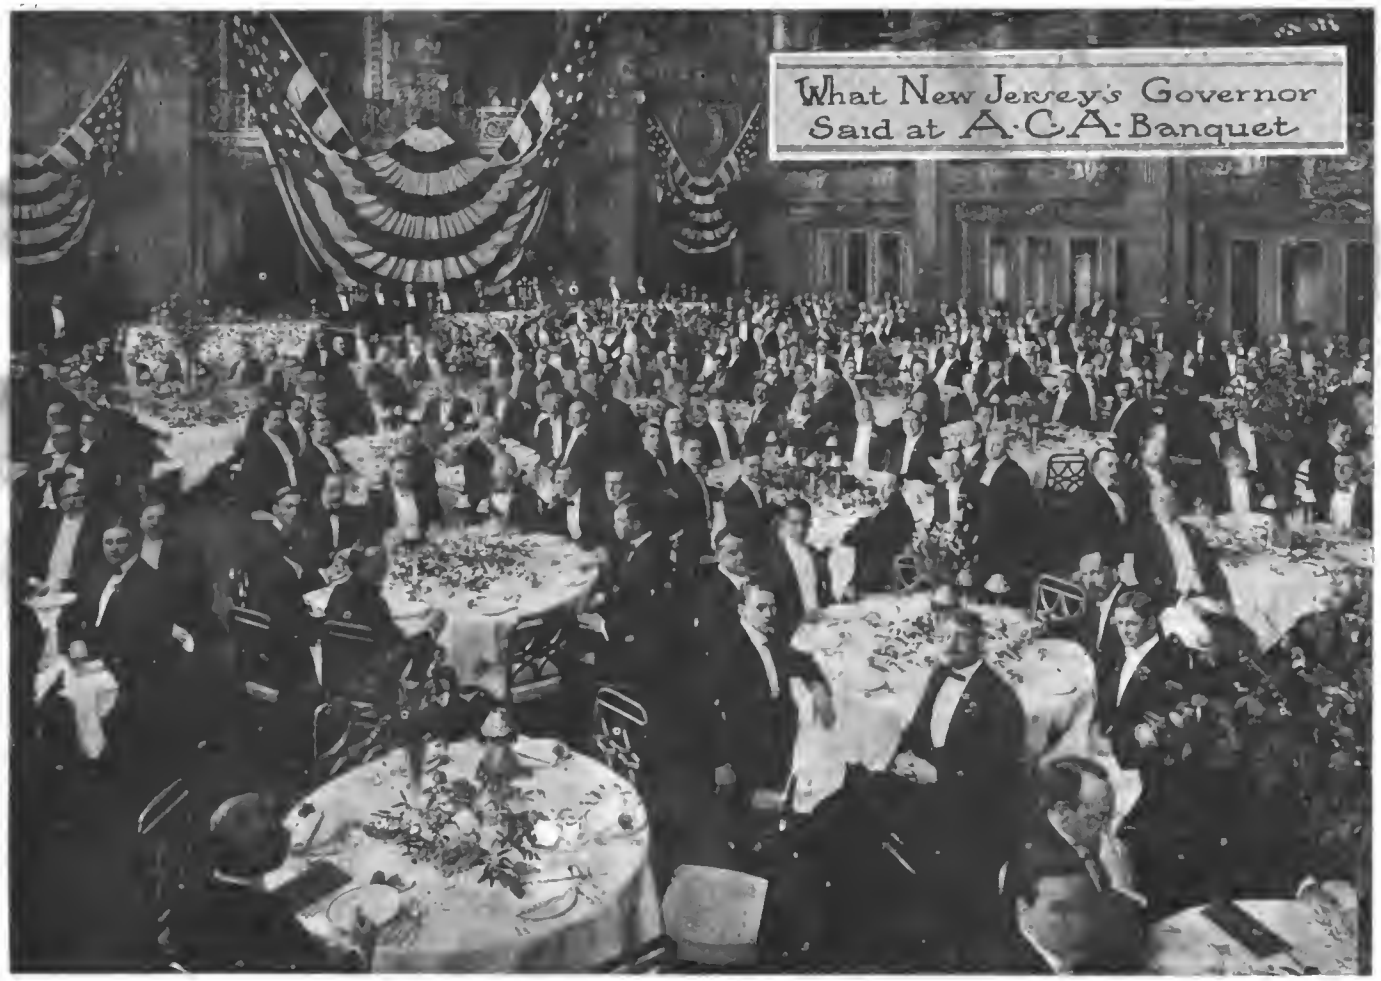
The scheme as considered best by the club, is to have the cars start from this city at 8 o'clock in the morning, running on a schedule of 19 miles an hour, and checking in at two places on each round, first Hackettstown and then Newark, arriving in this city on the first lap at 1 P. M., and on the final round at 6 o'clock in the evening. Pathfinders will go over the route to finally map it out, and as at present suggested, the ones chosen will be very popular, inasmuch as almost all kinds of road conditions, except very soft mud, will be found. There will be plenty of pleasant touring over the fine macadam roads, some strenuous traveling over rocky roads in the country, and at least one good hard climb on each trip over Schooley's mountain.

Hackettstown is 42½ miles from the start, exactly half way, and the proposed route would take the contestants out of Newark, then through Irvington, Chatham, Madison, Morristown, Mendham, Chester, German Valley, over the mountain and down into Hackettstown. The second stretch would take them up to Allamuchy, where a turn is made and the beaten path left for time, while the road is rocky enough to give the cars and drivers a good test. The course leads to Stanhope, through Port Morris and Dover. At this point there would be a choice of routes, one leading to Morristown and thence to Newark over the out-bound route. It is more likely that one leading from Dover through Rockaway, Denville, Pine Brook, and Montclair will be taken. This course would be covered twice, and a number of valuable prizes will be given for the best performances.

The committee in charge of the contest is: H. A. Bonnell, chairman; F. A. Croselmire, A. B. Le Massena, H. A. Bowman and D. C. Reynolds.



Sixth Annual Banquet of the New Jersey Automobile and Motor Club, Krueger's Auditorium, Newark, March 18.



Tenth Annual Banquet of the Automobile Club of America, Held March 25, at the Waldorf-Astoria, New York City.

UNDETERRED by the necessity of taking out a license and unmarked by a traveling number, the Governor of New Jersey on the evening of March 25 crossed the Hudson River and entered the adjoining commonwealth of New York State. Comfortably conveyed in a motor-driven vehicle to the Waldorf-Astoria, Governor Fort became the guest of honor at the tenth annual banquet of the Automobile Club of America. Speaking more or less impromptu, 'tis possible that New Jersey's chief executive may have been carried away by the enthusiasm of the moment and given utterance to sentiments to which heretofore he had been a stranger, for certainly his ideas have undergone considerable modification since the night a year ago when at the dinner of the New Jersey Automobile and Motor Club the then president of the American Automobile Association, William H. Hotchkiss, handled the New Jersey law so scathingly that the Governor impetuously took it upon himself to defend a law in the making of which he had had nothing to do. Then he said he believed in uniform laws, and that this could be brought about by the other States copying New Jersey's excellent statutes. At the A. C. A. function Governor Fort said:

I want to help, as I believe the New Jersey Legislature does, every reasonable act for the bettering of the automobile interests and of the operation of the automobile in our State. The problem is only to be solved in my judgment in one way. We have been doing too many things in this republic of ours by single States.

Interstate agreements are provided for under the constitution of the United States. With the consent of Congress any two States may make any agreement they please between themselves, and if New York and New Jersey and Connecticut and Rhode Island and Massachusetts and Maryland shall agree together on a method of travel by automobiles and a uniform fee for all these States, and it shall be approved, we shall need no further legislation on the subject, and we shall have one fee for all these States in the East.

Recently, through the initiative principally of Governor Hughes, there was held a conference of the commissioners on uniform laws of New York, New Jersey, Connecticut and Massachusetts, the result being the drafting of an automobile law intended to be acceptable to those commonwealths. This measure, it is stated, is shortly to be introduced at Albany, with chances favorable for its passage, though perhaps modified in minor particulars.

In the course of his talk of half an hour Governor Fort said among other things:

The automobile is here to stay, and Legislatures and all others may as well recognize that fact. That being a fact, we must have laws on the subject of speed that are clear and simple. They must be so that every man can read and understand them and make no excuse when he violates them.

We must have a speed limit such as shall not create a race of lawbreakers. I am opposed to putting in the statutes of our States or in the acts of Congress that which every man knows nobody intends to observe. It is not fair to the man who uses the highway, it is not fair to the public morality of the State to put restrictions in laws that cannot ordinarily be observed, I would have the laws fair and just to every man, and then I would enforce them. Every vehicle upon the public highway should carry a light of some kind. Every drunken driver should be deprived of his license and punished in some way for being drunk.

No summary arrest should be permitted upon the highway of a man driving an automobile, continued Governor Fort. He should only be stopped for the purpose of taking his number, and let the orderly proceeding in court go on later. No trap should be set anywhere for the purpose of catching people on the highway.

Our fees over in New Jersey I believe have been criticized. I believe the sentiment in our State to-day is in favor of making the laws so that you can come without paying extra license fees. Why shouldn't you come to New Jersey?

A Voice: "Because you rob us!"

We want you to come, and we are going to try and make it so that you will come.

Resentment at the attitude of the New Jersey lawmakers in ref-

erence to automobiling has been undisguised on numerous occasions, and the reference to being robbed met with approving laughter from parts of the big ballroom, as did other comments of irrepressibles who at times may have felt financially the sting of the Jersey constables.

Judge E. H. Gary, president of the A. C. A., divided the guests' table, those sitting with him being Governor Fort, ex-presidents Dave Hennen Morris, Winthrop E. Scarritt and A. R. Shattuck; Colonel John Jacob Astor, George F. Chamberlin, William G. McAdoo, William Pierson Hamilton, Cortlandt Field Bishop, Henry Sanderson, Robert Lee Morrell, Dr. Schuyler Skaats Wheeler, William H. Barnard, Colonel Austen Colgate, Duncan McDonald, of Montreal, and the Hon. Beverley Robinson.

J. B. R. Smith, commissioner of motor vehicles for New Jersey, was an interested listener, and others in evidence included Jefferson deMont Thompson, Charles J. Glidden, Robert Graves, Alan R. Hawley, Captain Homer W. Hedge, R. A. C. Smith, Philip T. Dodge, H. K. Burras, W. D. Gash, H. H. Law, C. J. Obermayer, Alfred Reeves, E. P. Chalfant, H. M. Swetland, Benjamin Briscoe, J. D. Maxwell, S. T. Davis, Jr., A. L. Riker, R. D. Garden, S. E. Stevens, Carl H. Page, Percy Owen, Horace DeLisser, Walter Christie, Frank Eveland, John Van Benschoten, F. D. Dorman, General John T. Cutting, Harry G. Fisk, Peter Fogarty, E. Rand Hollander, William B. Hurlburt, James Joyce, J. M. Lansden, A. L. McMurtry, E. J. McShane, F. E. Moscovics, E. S. Partridge, H. W. Nuckols, K. C. Pardee, Orrel A. Parker, A. P. Palmer, John F. Plummer, Jr., C. R. Teaboldt, Harry Unwin and A. H. Whiting.

Aside from the general remarks of Judge Gary about the club and the rather unexpected expressions from Governor Fort, there was no speechmaking, the others scheduled failing to appear. These were the Hon. Chauncey M. Depew, Congressman J. Van Vechten Olcott and State Senators Allds and Hill. But Chairman Ely of the banquet committee had provided several grand opera singers and artists who may have met the needs of the occasion in a manner more pleasing to the majority than would have been after dinner words of wisdom on automobile legislation, which subject the many are ever inclined to leave in the hands of those who find satisfaction in working for the good of the cause. One big disappointment came in the announcement that at the last moment Miss Mary Garden could not be present owing to a hard cold. Madame Doria and Mlle. Trentini, one a contralto and the other a soprano, were substitutes, with Signor Sammarco and Herr Meizel also contributing brilliantly, the first with some exquisite violin playing. Some 450 attended the banquet. The souvenirs were elaborate menu cards.

THE AUTOMOBILE CALENDAR

AMERICAN.

Shows.

April 10-17.....Brooklyn, N. Y., Clermont Rink, First Annual Automobile Show, Long Island Automobile Club.
April 17-24.....Montreal, St. Lawrence Hall, Fourth Annual Automobile Show, auspices of Automobile Club of Canada. R. M. Jaffray, Manager.

Races, Hill-climbs, Etc.

April 22.....Chattanooga, Tenn., Hill Climb on Lookout Mountain, Lookout Mountain Automobile Club.
April 24.....Philadelphia, Roadability Run to Atlantic City, Quaker City Motor Club.
April 26-May 1...New York City, Second Annual Automobile Carnival, New York Automobile Trade Association.
April 26.....New York City, Second Annual Hill Climb, Fort George-New York Automobile Trade Association.
April 28-30.....Pittsburg, Pa., Gazette Times-Chronicle Telegraph Three-Day Endurance Run. Indorsed by Automobile Dealers' Association.
April 30.....New York City, Endurance Run, New York Automobile Trade Association.
May 3-6.....Harrisburg, Pa., Third Annual Endurance Run, 700 miles, Washington, Baltimore, Scranton, Motor Club of Harrisburg.
May 10-13.....Detroit, Mich., Four-day Endurance Run, Detroit Automobile Dealers' Association.
May 11-15.....Philadelphia Reliability Run to Pittsburg and Return, Quaker City Motor Club.
May 18-19.....Norristown, Pa., Second Annual Endurance Run, Norristown Automobile Club, to Hagerstown, Md.
May 22.....Hartford, Conn., 200-Mile Endurance Run, Hartford Automobile Club.
May 22.....Newark, N. J., Third Annual Endurance Contest, New Jersey Automobile and Motor Club, 190 Miles.
May 31.....Wilkes-Barre, Pa., Annual Hill Climb, Giants' Despair Mountain, Wilkes-Barre Automobile Club.
May 31.....Bridgeport, Conn., Annual Hill Climb, Sport Hill, Automobile Club of Bridgeport.
June 1.....New York City, Start of Transcontinental Contest to Seattle, for Alaska-Yukon-Pacific Exposition, M. Robt. Guggenheim Trophy.
June 11-12.....Philadelphia, 24-Hour Track Race, Quaker City Motor Club.
June 12-14.....New York City, Catskill-Berkshire Endurance Contest, New York Automobile Trade Association.
June 18-19.....Chicago, Stock Chassis Race for Cobe Trophy and Light Car Race.
June 21-26.....Binghamton, N Y., Fourth Annual Endurance Run, Albany, Boston, Hartford, Newburg, Binghampton Automobile Club.
June 22-28.....Albany, N. Y. FifthAnnual Tour, Bretton Woods, Portsmouth, Boston, Albany Automobile Club.
June 24-26.....Montreal, Blue Bonnets Track, Race Meet. R. M. Jaffray, Manager.
July 3 and 5.....Wildwood, N. J., Straightaway Races, Motor Club of Wildwood.
July 4.....Los Angeles, Cal., Southern California Automobile Dealers' Association. Road Races, 250 Miles for Large Cars; 150 Miles for Light Cars.
July 7.....Detroit, Start of Sixth Annual A. A. A. Tour for Glidden Trophy.
Sept. 15.....Denver, Col., Start of Flag to Flag Endurance Run to Mexico City.
Oct. 7.....Philadelphia, Second Annual Stock Chassis, 200-Mile Race, Fairmount Park, Quaker City Motor Club.
Dec. 29-30.....Philadelphia, Fourth Annual Mid-Winter Endurance Contest, Quaker City Motor Club.

FOREIGN.

Races, Hill-climbs, Etc.

March 31-Apr. 14.Italy, Monaco, Annual Motor Boat Regatta and Championships.
April 11-18.....Austria-Hungary, Prague, Automobile Exhibition, Hill Climb at Koenigsaal, Automobile Club of Tcheque.

June 20.....France. Boulogne-sur-Mer Course, Voiturette Race, Auspices "L'Auto."
July 13-17.....Belgium, Ostend Automobile Race Week.
Aug. 22-29.....France, Reims, Aeroplane Races and Grand Prix, Aero Club of France.
Sept. 5.....France, Mont Venteoux Hill Climb.
Sept. 19.....Austria Semmering Hill Climb.

M. C. A. WON'T SUPPORT CROSS-COUNTRY TEST

NEW YORK, March 30.—Manufacturers and importers of automobiles, in a regular meeting of the Manufacturers' Contest Association, held in this city to-day, after considerable discussion and hearing representatives of the Alaska-Yukon-Pacific Exposition, the Automobile Club of America, and the New York *Times*, decided not to give the support of the recently formed organization in the promotion and running of two proposed transcontinental contests. The M. C. A. stated, however, that it was not opposed to such contests, but inasmuch as the rules for the run to Seattle did not meet with its approval, it did not feel that it should sanction another event, as a rival to the one sanctioned by the Automobile Club of America. This meant the proposed contest of the New York *Times*, the management of which clearly stated that it did not intend to promote any such event, except that it met with the approval of a substantial portion of the automobile industry.

These are the resolutions officially promulgated:

WHEREAS, The Manufacturers' Contest Association advocates and will lend support to races and contests that furnish to the public a basis of the comparative merits of cars and that demonstrate to the manufacturers where improvements can be made in material and construction, to the end that only the best in motor cars may be offered to the buying public; therefore, be it

RESOLVED, That the Manufacturers' Contest Association in meeting decides unanimously that for the following reasons it cannot lend support to the proposed race from New York to Seattle, although sanctioned by the Automobile Club of America, whose right to grant a sanction for this event is unquestioned:

First—The entry blanks distributed among the manufacturers state that it is a "race," and as such it cannot but place a premium on speeding in violation of State laws, which is contrary to the position automobile makers have taken with the various State Legislatures.

Second—The rules on the entry blank, which, among other things, provide that engines, axles, gears, etc., may be changed twice and only the original frame brought to Seattle, are not for the betterment of motor car manufacture.

Third—The entry blank statement, "The first car arriving at Seattle will be declared the winner" presupposes a road race without regard to speed regulations, the prize going to the car whose drivers most consistently and persistently disregard the conditions and laws under which the authorities permit the use of motor cars.

Fourth—Another rule provides that the crew of a car may drive continuously from New York to Seattle, or as nearly so as the endurance of the crew, relaying each other, will permit. The contest would therefore be strung out over a period of hours and days, making it impossible to safeguard the highways and the public for the continuous time necessary.

Fifth—The rules as a whole, or the explanation of the race representatives, do not assure the Manufacturers' Contest Association that the contest will advance either the pastime or the industry.

Sixth—The excellent record of the Automobile Club of America in the sport and industry makes it a matter of regret that it should have given its sanction to the rules that are offered for the government of this proposed race.

Questions of speed and of changing parts of cars seem to be the reasons predominant in influencing the M. C. A. against the contest. The rules do not place a time allowance which would make the contesting cars keep within the various speed laws; and engines, axles, gears, etc., can be changed twice in the trip across America, only the original frame having to be used throughout. While Mills and Moore and Robert Lee Morrell, of the Automobile Club of America, express regret that the manufacturers and importers have taken a stand against the event, they state that nothing shall deter them in the holding of the contest. The management claims positive assurances of enough cars to make the event a success.

Benjamin Briscoe, president of the Association, presided at the M. C. A. meeting, while Howard E. Coffin, chairman of the Rules Committee, was in charge of that section of the organization. A constitution and by-laws were adopted, and the following directors elected: Benjamin Briscoe, Maxwell-Briscoe Motor Co.; William E. Metzger, Everitt-Metzger-Flanders Co.; H. O. Smith, Premier Motor Mfg. Co.; H. E. Coffin, Chalmers-Detroit Motor Co.; Windsor T. White, White Company.

The rules for the Cobe Cup Contest in Chicago and other contests came in for consideration, and the Rules Committee had a prolonged session, which lasted until after midnight. An announcement is expected through the A. A. A. Contest Board.

Those in attendance at the meeting were:

Edgar Apperson, Apperson; A. P. Brush, Buick; H. E. Coffin, Chalmers-Detroit; E. H. Tangeman, Lancia; C. M. Hamilton, Isotta; H. G. Farr, Knox; A. L. Riker, Locomobile; H. A. Lozier and C. H. Emise, Lozier; Benjamin Briscoe, Maxwell; R. H. Croninger, Pennsylvania; G. A. Weidely, Premier; Paul Lacroix, Renault; F. B. Stearns, Stearns; F. A. Barker, Stoddard-Dayton; Walter C. White, White; E. P. Chalfant, A.L.A.M.; Alfred Reeves, A.M.C.M.A.

There were also represented by proxy: Mitchell Motor Car Company, National Motor Vehicle Company, and the Pierce-Arrow Motor Car Company.

Telegrams and letters were received from the following makers, voting against supporting the proposed New York to Seattle contest:

Mora Motor Car Company, Palmer & Singer Mfg. Company, Peerless Motor Car Company, Winton Motor Carriage Company, Hudson Motor Car Company, Bartholomew Company, Nordyke & Marmon Company, Dorris Motor Car Company, Walter Automobile Company, York Motor Car Company, Gearless Motor Car Company, Brush Runabout Company, Moon Motor Car Company, Reo Motor Car Company and Packard Motor Car Company.

SEATTLE PATHFINDER REACHES CHICAGO.

CHICAGO, March 30.—Striking good roads for almost the first time since leaving Albany, N. Y., the around-the-world Thomas car, which is laying out the route of the transcontinental contest to the Seattle Exposition, reached the Windy City this evening, having run from Ligonier, Ind., 114 miles, to-day. In the run from Cleveland, checking stations were established at the Hotel Secor in Toledo, and The Oliver in South Bend. Great enthusiasm was shown all along the route, crowds and cars meeting the tourists everywhere. They intend to push out toward St. Louis to-morrow.

DISCUSSING THE USE OF CHAINS.

ALBANY, N. Y., April 1.—A hearing is taking place to-day at the City Hall, under the auspices of the State Highway Commission, primarily for the purpose of discussing the question as to whether the use of chains on tires of automobiles should be regulated or prohibited, and with reference also to other anti-skid devices. Automobilists are well represented.

LACROIX'S RENAULT GIVEN CLEAN SCORE.

NEW YORK, March 29.—A fifteenth perfect score car has been added to the finishers of the mid-winter run from this city to Boston, March 11, for the Contest Board of the A. A. A. at a meeting this evening, gave Paul LaCroix, who drove his Renault, a clean score. The decision of Referee L. M. Bradley was upheld, in penalizing Mr. LaCroix 16 points for lateness at Hartford, inasmuch as the rules provided for that contingency. But it was shown that the Renault was held up by police on a charge of which he was cleared, and inasmuch as he was not at fault, the board voted to restore the lost points. Mr. Bradley, as referee, did not have the authority to do this.

DECIDES MOTORCYCLES ARE VEHICLES.

LANSING, MICH., March 30.—The State supreme court to-day decided that motorcycles are vehicles, within the meaning of the law relative to automobiles and motor vehicles, and upheld a conviction of H. G. Smith, of Detroit, for violating that law with a motorcycle. Smith had appealed his case.

THE LICENSING OF ALL OPERATORS.

Anyone, owner or hired chauffeur, entrusted with the driving of a motor-driven vehicle should be required to take out an operator's license, such license to be revocable for criminal or grossly inconsiderate use of the highways, is the opinion that comes from the annual meeting of the New York State Automobile Association, a body containing some 4,600 members distributed among forty-five clubs located in various parts of the State. This expression is qualified by the demand for concurrent action in substituting "reasonable and proper speed" for the present unsatisfactory miles-per-hour limitations. In the same resolution, and interrelated, is the proposition to accept an annual registration fee if the money is expended upon improved roads and motor vehicles are not taxed as personal property.

Upon the question of licensing all operators there is now a striking unanimity that has gained ground rapidly in the past twelvemonth, owing probably to the great increase in the number of automobiles on the roads. The inconsiderate must be punished and the incompetent must not be permitted to drive.

It is urged with much degree of logic that the drivers of all vehicles—motor or horse-drawn—should be licensed, especially in the large cities, where traffic is heavy and varied, and the same argument is put forth in connection with an annual registration fee. Decided by legal interpretation alone, it would appear that there could be no doubt that the ruling of the courts would say in both instances that it was unfair discrimination against one class of road users to exact the fee from automobilists alone.

However, this might not prevent legislatures in which the farmer has a big voice from imposing retaliatory measures for having his horse-drawn vehicles placed upon the same basis as automobiles in the matter of registration and licensing of drivers. While both vehicles use and wear out the roads, the new vehicle has to meet with antagonistic progress, as has always been the case with any innovation. But the newcomer is demonstrating its superiority for all purposes, which means that its supremacy is nearing complete achievement at a pace astounding even to those who have believed in it from the outset.

There is timely need of suppressing the reckless driver, and it is a task for the automobile associations themselves to come forward and aid in clearing the highways of these few, who bring such great discredit upon the many and also prompt legislation which interferes with the intelligent use of the pleasurable necessity of the age. Only by taking them from their places at the steering wheel, occasionally with jail sentences, and in outrageous instances inflicting a permanent revocation of license, can the law-abiding autoist secure for himself the road rights of an American citizen.

* * *

STARTING DEVICES REVEAL PROGRESS.

A casual glance over the field of self-starting devices shows that progress has been made in the past year. This advance has been made in the face of much popular opposition. At first sight, it would seem that owners and drivers would be the best friends of these contrivances, but history proves that the reverse is true. In fact, it is no stretch of imagination to say that the people most interested have been the worst enemies.

This opposition takes two forms, passive indifference and active hostility, of which the former is by far the more dangerous. If the automobiling public wants starting devices, all that is necessary is to indicate that want in clear unmistakable language. The history of the automobile business shows that whatever has been demanded has been forthcoming.

An article in this issue calls attention to the mechanical features of a number of self-starters, but the list of makers who are now fitting them or will do so upon demand is not included therein. If this were so, readers would be astonished at their prominence and large numbers. On the other side of the ocean, Renault, Saurer, Mors, Hallford, Brasier, Safir, and others are all prominent; in our own country, Winton and other Western cars have equally good reputations, yet all these have put out self-starting arrangements. In placing their stamp of approval upon these, the makers have taken the chance that if the devices failed their own business would be seriously affected.

The gradual tendency of the times, the signs of the public awakening, may be seen by following the advertising of the firms mentioned, and noting therein what is featured. This featuring of a device whose necessity should be self-evident is the mark of the campaign of instruction now being carried on.

BELIEVES ALL OPERATORS SHOULD BE LICENSED

ROCHESTER, N. Y., March 29.—The New York State Automobile Association at its annual meeting to-day placed itself squarely upon record as being in favor of requiring the issuing of licenses to the operators of all motor-driven vehicles, with penalties for revocation, and the imposing of an annual registration fee, providing automobiles are not taxed as personal property and "miles-per-hour" is eliminated and "reasonable and proper speed" substituted.

While the majority opinion of those present was in favor of having the amount of the registration fee decided by the diameter of the vehicle's largest tire, there were expressions in favor of both horsepower and weight classifications. Concerning the wisdom of licensing all operators, however, there was unanimity that the time had come for such a requirement, concurrent, however, with the disappearance of the miles-per-hour conditions which make trapping and unfair arrests a most tempting proposition for many rural communities.

After a three years' occupancy of the presidency of the State Association, Oliver A. Quayle declined a re-election and was succeeded by Herbert A. Meldrum, of the Automobile Club of Buffalo and one of its former presidents. The other selections were: First vice-president, Frank G. Webb, Long Island Automobile Club; second vice-president, M. L. Ryder, Albany Automobile Club; third vice-president, S. C. Tallman, Automobile Club of Auburn; treasurer, H. W. Smith, Syracuse Automobile Club; secretary, Bert Van Tuyle, Automobile Club of Rochester.

C. D. Hanks, who has been secretary during Mr. Quayle's administration of affairs, also declined re-election.

Morning and afternoon sessions were necessary to dispose of the routine and special matters. The most important action is expressed in the resolution offered by President J. M. Satterfield, of the Automobile Club of Buffalo, which reads as follows:

RESOLVED, That the New York State Automobile Association places itself on record as being in favor of the issuing of licenses to the drivers of all motor vehicles, with the instituting of penalties for suspension or revocation of such licenses, and, furthermore, agrees to an annual registration fee for motor vehicles, based upon the diameter of the largest tire used on the vehicle, the fee not to exceed $10, provided that such money be expended in the maintenance of improved highways and such motor vehicles are not taxed as personal property and the miles-per-hour restriction is eliminated and reasonable and proper speed substituted.

Ex-President Quayle will continue as chairman of the State legislative committee, his Albany residence making him a particularly valuable man in the position.

In the evening the visiting directors were guests at the annual banquet of the Automobile Club of Rochester, to the presidency of which H. G. Strong was re-elected at the annual meeting in the afternoon. The banquet was held at the Genesee Valley Club, and was attended by fully one-half of the nearly 600 members of the automobile club. President Strong, after telling of the progress of the club in the past and prophesying as to its future, turned the toastmaster's roll over to "Starter" John H. Stedman, retaining for himself the rôle of "Pacemaker."

There were songs in plenty, and the invitation that everybody should sing was vociferously followed. Well-known local politicians brazingly gloried in their presence, and one of them, Police Justice Chadsey, was elected to honorary membership.

Those who talked included President-elect Meldrum, and ex-President Quayle, of the State Association; George H. Diehl, chairman of the A. A. A. Good Roads Board; President J. M. Satterfield, of the Automobile Club of Buffalo; A. G. Batchelder, editor of THE AUTOMOBILE; F. H. Elliott, secretary of the A. A. A.; and D. H. Lewis, secretary of the Automobile Club of Buffalo. Of course Judge Chadsey had something to say.

The State association has 45 clubs and about 4,500 members.

PRESENT CONNECTICUT LAW "SAFE."

HARTFORD, CONN., March 29.—Opinions as to the status of the present automobile law in the State of Connecticut and the general situation in the State in reference to legal matters held the attention of the members of the Automobile Club of Hartford at their dinner on last Friday evening. Arthur L. Shipman, an automobilist and prominent lawyer, was the first to voice the sentiment that the present law is "safe," meaning that there is not a strong likelihood of its being changed, and his remarks were concurred in by Harrison B. Freeman, Jr., another autoist and member of the bar. Mr. Freeman, who was for some time the prosecuting attorney of the local police court, was especially desirous that the club members should obey the present statutes. The club will do all in its power to maintain the present law.

NEW YORK STATE PROTECTIVE ASSOCIATION.

ALBANY, N. Y., March 30.—The National Highways Protective Association was incorporated in this city to-day, its purpose being to prevent the improper use of public highways by vehicle owners, to secure better roads, and more uniform laws for their use. The incorporators were: Lawson Purdy, Gilford Hurry, G. W. Burleigh, J. H. Coit, E. S. Cornell, M. J. Einstein, W. H. Llewellyn, A. D. Middleton, and J. F. Potter, all of New York.

CAPITAL CLUB GETS SHERMAN; AFTER TAFT.

WASHINGTON, D. C., March 29.—Vice-president James S. Sherman has just been elected a member of the Automobile Club of Washington, which is an A. A. A. club. The members of the club, in view of President Taft's readiness to use motor vehicles, expect within a short time to receive his consent to be enrolled as a member of the club.

IN HONOR OF PRESIDENT L. R. SPEARE.

BOSTON, March 29.—In honor of the election of Lewis R. Speare to the presidency of the A. A. A., the Bay State Automobile Association will give a banquet to him, April 6, at the Hotel Carlton. Prominent automobilists from different parts of the country have been invited to attend.

At a meeting of the directors of the Bay State Automobile Association, held March 25, Mr. Speare asked that he be relieved of the presidency, in view of his increased A. A. A. duties. This was accepted with regret, and Frederic Tudor was elected.

Mr. Tudor is an enthusiastic automobilist, owning several cars, and was one of the pioneers in the sport in this part of the country. He holds the first operator's license ever issued by the Massachusetts Highway Commission, and since 1903, when the first automobile law was passed, has cars have had the distinction of bearing registration No. 1. He was formerly secretary of the Massachusetts Automobile Club, is president of the Automobile Owners' Association, and is an officer of one of the local taximeter cab companies.

NEW LAW IN JERSEY PASSES HOUSE.

TRENTON, N. J., March 30.—Automobilists felt justly happy to-day when the Bradley Senate bill passed the House, although rural assemblymen vainly sought to amend it. This bill allows automobiles a speed of 25 miles per hour, provides that violations of the law must continue for one hour to warrant arrest, and cuts the fees of justices of the peace in two. Now that this measure has been safely started, it is felt certain that the Frelinghuysen measure, which permits the State to recognize the licenses of other States, will go through the Legislature. The Colgate bill has been withdrawn.

SYRACUSE SHOW SUPERLATIVELY SUCCESSFUL

SYRACUSE, N. Y., March 27.—Starting under most unfavorable weather conditions, snow, rain and sleet, but which did not seem to have an appreciable effect upon the attendance, the first automobile show ever held in this city was opened last Wednesday evening by Mayor Alan C. Fobes. For three full days thereafter the State Armory was crowded, and a strong note was sounded for a still greater exhibit next season.

At the opening every exhibit, both in the main hall and in the basement, where the accessories were shown, was in its place. The exhibits contained many novelties. One was a little Brush runabout, with "Cleo," the wax man, at the wheel, who defied the crowd to tell at first glance whether he were alive or not. Immediately after the opening ceremonies Mayor Fobes inspected the building, accompanied by Manager Lewis, President of the Trade Association C. Arthur Benjamin, Chairman M. W. Kerr, of the show committee; Vice-President H. D. Van Brunt and H. H. Franklin.

Thursday and Friday it became evident that all Northern and Central New York was interested in the Armory exhibition. Every train brought visitors from Watertown, Utica, Rome, Oswego, Auburn, Binghamton, Elmira, Rochester, Buffalo, Albany, Ithaca and scores of nearby villages and towns. With a total of 4,000 attending the automobile show on Saturday, the closing day of the exhibition, the show came to an end. Already plans are formulated for a bigger and better one next year. The show "caught on" with the public, and its success surprised and delighted the men responsible for it. The total attendance for the four days was upward of 12,000.

Exhibit of Air-Cooled Franklins at Syracuse Show.

According to figures given by the dealers there have been eighty cars disposed of, the prices averaging $2,000 each, making a total of $160,000 spent for the machines. Over $5,000 worth of accessories and supplies have been purchased from the basement, where the purveyors have been writing orders for tires, engines, speedometers, lamps, oil, etc. Every dealer had his sales department reinforced by all the sub-agents throughout Central New York. Sales have included everything from the $500 runabout to the $5,000 limousine. There was an especially big business done in motor trucks. Those who exhibited were:

AUTOMOBILES.

Amos-Pierce Automobile Company: Chalmers-Detroit, Stevens-Duryea, Lozier.
Oldsmobile Automobile Company: Oldsmobile.
Buick Motor Company: Buick.
Syracuse Autocab Company: Thomas Selden.
H. H. Franklin Mfg. Company: Franklin.
Leon Conde, Inc.: Brush.
C. Arthur Benjamin: Packard, Elmore, E-M-F.
Maxwell-Briscoe-Syracuse Company: Maxwell.
Mora Sales Company: Mora, Regal.
Genesee Motor Car Company: Peerless, Cadillac, Pope-Hartford.
F. L. Wightman: Winton.
Syracuse Motor Car Company: Ford, Overland, Pullman.
W. E. Hookway: White.
Chase Motor Truck Company: Chase.
C. E. Wethey: Reo.

ACCESSORIES.

Atlas Sales Company.
Syracuse Supply Company.
E. B. Van Wagner Mfg. Co.
C. A. Benjamin.
Buick Motor Company.
J. A. Seltz.
W. F. Poison.
Central City Oil Company.
C. E. Mills Oil Company.
F. L. Reed.
Amos-Pierce Company.
O. M. Edwards Company.
Clinton Vulcanizing Company.
Syracuse & Elbridge Glove Co.
Maryland Casualty Company.
Wonder Mfg. Company.

PITTSBURG'S THIRD SHOW A RECORD BREAKER

PITTSBURG, PA., March 29.—Smoky City automobilists, and thousands of people who are not automobile owners, are being treated this week to one of the most successful automobile shows of the season, proven to be such not only by the enthusiasm shown when the doors of Duquesne Garden opened on last Saturday evening and by that seen to-day, but by the exhibitors and exhibited themselves. This is the third annual show, held under the auspices of the Pittsburg Automobile Dealers' Association, better staged than ever, with more extensive and harmonious decorations, increased number of exhibitors, more evenly divided spaces, and consequently a far more pleased attendance.

Indeed, not one of the 8,500 persons who crowded into the big hall on the initial evening expressed anything but delight at the scene, and those automobilists who have gone from city to city in their annual tour around the show circuit have voiced the same sentiments with regard to this one. The brilliant lighting, and the white, green and gold colors in the decorative scheme please everyone, and the 100 or more exhibitors, the ones who are so often hard to satisfy, are enthusiastic in their praise of the setting and general management. Chairman W. N. Murray and his associates, Robert P. McCurdy, C. F. McLaughlin and G. P. Moore were the recipients of many congratulations, and they seemed thoroughly well pleased and repaid for the long period of preparatory work.

It is felt that this show will be the winner for several reasons: far more interest has been shown during its preparation, more exhibitors than on previous occasions have taken space, more space was sold than at any other Pittsburg show, more high-class cars and complete lines of accessories are represented, the arrangement of the hall has been improved, and, perhaps more than these, the show committee has worked harder, been better organized, and has accomplished more than has any other body which has had these festivities in charge. Moreover, there was an unbroken line of exhibits seen when the visitors were admitted, and there are no late comers to disturb the present splendid arrangement. On either side of the long promenade space on the main floor of the Garden are ranged the automobiles. Above and around the tiers of boxes are the accessory exhibits. The stage and the foreground are well filled with exhibits of cars, and up to the very hour of opening applications were made by agencies who desired space for their cars.

The walls of the big Garden are beautifully decorated with great mural paintings of natural scenery, with the automobile always in the foreground. Immense folds of silkaline, set electric figures, bas-relief work, splendid silver trophies won at other shows or other races, and a profusion of costly potted plants and palms make the Garden a very wilderness of beauty. A band is on hand to furnish music, but the crowds have shown a great partiality for the big 36-note Gabriel horn, which was such a welcome addition to the New York, Kansas City, Cleveland and other shows, and the big horn would have been kept busy if it had responded to all the encores. Every effort has been made to have the show a source of genuine profit to the exhibitors.

The display of cars is magnificent, there being all sizes, styles, colors and prices, so that everyone has a chance, and the polished chassis have been the centers of interest here, as they have been elsewhere, dividing the crowds between those who are mechanically inclined and those who look only at the finishes. It is hard to imagine the business depression of the recent financial stringency in this city, and, although it has taken two shows to warm up the buying public of one of the busiest cities in this country, it is apparent that the awakening has been a strong and pleasant one. All over the show there are reports of growing trade, and it is expected that a number of retail sales will be made, in addition to the placing of a few sub-agencies. The suburbs of the city offer excellent roads, and autos are increasing.

Duquesne Garden, Scene of Pittsburg's Third Annual Show, Contains a Representative Collection of the Industry's Best Productions.

Another respect in which the show is noteworthy is in the matter of accessory exhibits, for, although unsanctioned, every available corner where a display of accessories could be planted is taken, and around all of the booths are seen interested crowds, discussing with the dealers, for Pittsburgers have found that economy in up-keep is due in a great measure to the kind and grade of accessories purchased. Special displays of oils, tires, bodies and windshields are on hand.

A number of automobile celebrities have arrived to attend the week of celebration, among them being: E. L. Thomas, E. R. Thomas Motor Company; Walter C. White and R. H. Johnston, White Company; Harry Fosdick, Hol-Tan Company, Lancia importers; C. J. Jamison, Dayton Motor Car Company; W. C. Churchill, Winton Motor Carriage Company; Frank Pierce, Gaeth Automobile Company. Mayor Reyburn, of Philadelphia, sent his greetings across the mountains to Mayor Guthrie, of Pittsburg, in a Maxwell, Jr., car, which is known for its 2,000 and more miles non-stop tendencies, and arrived at Duquesne Garden Saturday morning. Agents, salesmen and prospective buyers of Western Pennsylvania, Eastern Ohio and West Virginia are arriving in good numbers to take in the show, and by midweek it is expected that the nightly attendance will be much larger.

Pittsburg has some products of its own in the Belden, Pittsburg-Six and automobile bodies. The Belden Motor Car Company has so far manufactured its car only upon a small scale, but it is now preparing to erect a plant which will have an immense output. The Fort Pitt Motor Manufacturing Company shows its "Pittsburg-Six," manufactured at New Kensington, a short distance up the Allegheny River. The concerns exhibiting bodies are the L. Glesenkamp & Sons Company and the E. J. Thompson Company. Accessory makers of this city included are: The Union Automobile Tire Repair Company, Manchester Automobile and Machine Company and O. J. Brackney.

The complete list of exhibitors of both automobiles and accessories is given herewith:

AUTOMOBILES.

Arlington Motor Car Co.: Pittsburg, Jackson.
Anderson Automobile Company: Wilkinsburg, Atlas.
Banker Bros. Co.: Stevens-Duryea, Chalmers-Detroit, Pierce-Arrow.
Bellefiel Motor Car Co., DeLuxe, Woods Electric, Couple Gear, Oakland.
Belden Motor Car Co.: Belden.
Buick Motor Car Co.: Buick.
Benson, B. F.: Studebaker.
Collins, D. P.: Lozier.
Eastern Automobile Co.: Atlas.
East End Automobile Co.: Waverley Electric, Pope Hartford.
Fort Pitt Automobile Co.: Locomobile.
Fort Pitt Motor Manufacturing Co.: Pittsburg-Six.
Hamilton Automobile Co.: Kissel Kar, Middleby.
Hiland Automobile Co.: Peerless, E-M-F.
Imperial Motor Car Co.: Cadillac.
Speedwell Automobile Co.: Speedwell Schacht.
Keystone Automobile Co.: Welch, Stoddard-Dayton, Velie, Columbus, Electric.
Maxwell-Briscoe Co.: Maxwell.
Mutual Motor Car Co.: Stearns, R. & L. Electrics.
Overland Motor Co.: Overland.
Olds Motor Works, Pittsburg Branch: Oldsmobile.
Premier Sales Co., Lts.: Premier Reo.
Pittsburg Automobile Co.: Thomas.
Regal Agency, Wagner & Feicht: Regal.
Standard Automobile Co.: Packard-Franklin.
Winton Motor Car Co.: Winton.
Wilkinsburg Automobile Garage: Elmore, Baker Electric.
The White Co.: The White Steamer.
Milhuish & Hemphill: Palmer-Singer and Simplex.
F. W. Fisher: Mora, Jewell, Marmon.
Co-Operative Automobile Co.: Moline.
Acme Motor Car Co.: Acme.
Pittsburg-Mitchell: Mitchell.
Matheson Agency: Matheson.
E. J. Thompson Co.: Automobile Bodies.

ACCESSORIES.

Rider Hotel.
Salman, John A.
Saunders & Bremer.
Standard Automobile Company.
Westinghouse Company.
Woodwell, Jos. Company.

RUSSIAN GOVERNMENT BUYS THE CLEMENT AIRSHIP

PARIS, March 25.—Adolphe Clement's aerial yacht, *Bayard-ment,* has just been sold to the Russian government to be used for army purposes, and is now undergoing trials previous to delivery. The airship, which was only launched a few months ago, and was announced to have been built for Mr. Clement's own personal use, is of the improved Partie type, and was produced by the Astra Company. The Bayard-Clement factory attended to the fitting of the engines, the power plant being a 120-horsepower, four-cylinder racing motor used on one of the 1906 Grand Prix cars. It drives a two-bladed propeller placed forward, and commanded through a reducing gear. Since then a six-cylinder engine of about the same power has been built, but had not been placed in position when the sale was effected. Up to the present the balloon has been used for pleasure trips, Mr. Clement on several occasions traveling from his country residence to his Paris factory by means of his aerial yacht. It has also been a very effective means of publicity, for on several occasions, notably during the holding of the annual Salon, it was flown over the city of Paris at noon, sufficiently low for the flaming characters on its side and rudder to be visible to all the frequenters of the boulevards.

A second French airship for the Russian government is under construction at the Lebaudy establishment at Moisson, near Paris, and is expected to be ready for delivery about the month of May. Orders have been placed with Melvin Vaniman, the American engineer, responsible for the construction of the mechanical portion of the Wellman polar airship, for two portable sheds to house war balloons. These sheds, which are of a special design, can be erected in four hours and taken down in half that time. They are specially designed to be mounted on automobiles in order to travel over country to a new headquarters that may be designated by the pilot of the airship.

Walter Rutt, Germany's well-known cycle racer, has turned aeronaut; a patron has ordered a Wright aeroplane for him, and he will take a course of lessons from the one and only Wilbur. A Wright aeroplane has been bought by the Strassburg firm of E. E. Mathis, and will be exhibited at the Frankfort show.

LANCASTER CLUB ELECTS OFFICERS.

LANCASTER, PA., March 29.—With the record of a successful year behind them, and the prospects bright for the success of the coming year, the members of the Lancaster, Pa., Automobile Club held their annual meeting at Lancaster on a recent evening and elected officers for the coming year. A banquet preceded the meeting. One of the features of the evening was an address by Hon. Frank B. McClain, ex-Speaker of the Pennsylvania Legislature, in which he is still a member. He showed the futility of hoping for the passage by the present Legislature of the bill providing for the State highway from Philadelphia to Pittsburg, on account of the depleted condition of the State treasury, and urged the club to support the efforts being made to raise $50,000,000 by a bond issue for the construction of State highways. New York will soon have the best roads in the United States, he said, and this is the manner in which they are being secured.

There was a spirited contest for the offices, indicating keen interest in the club. The officers elected were: President, H. C. Schock, Mount Joy; vice-president, Dr. J. F. Trexler, Lancaster; secretary, J. D. Rider, Lancaster; treasurer, Dr. W. H. Trout, Lancaster. Directors: Fred F. Groff, Lancaster; Geo. W. Kinzer, New Holland; Dr. Donald McCaskey, Witmer. The report of the secretary showed that during the year the membership increased from 107 to 153, exclusive of the ten elected at the meeting.

Dr. F. Magee, Esq., a member of the State committee on good roads, made an address in which he strongly urged the use of the King drag on dirt roads. Its adoption has met with successful results, and the Lancaster Club decided to conduct several public demonstrations to interest the farmer and show him how cheaply good roads could be had. Assurance was received from several turnpike companies that the roads of which the club complained would be repaired upon the advent of seasonable weather.

PETREL TO BE MADE IN MILWAUKEE.

MILWAUKEE, WIS., March 29.—An announcement of more than ordinary interest was made in Milwaukee early this week, when negotiations were closed by the Petrel Motor Car Company, of Kenosha, Wis., for a long-term lease of the Pfister & Vogel Leather Company's Virginia Street Foundry in Milwaukee, and that on May 1 the Kenosha works will be moved to Milwaukee. The company has been occupying the former Visible Typewriter Company plant at Kenosha, Wis., now owned by the Badger Brass Manufacturing Company. The Petrel friction drive car has been successful from the start. The demand is fully equal to the supply, and is expected to greatly exceed it before long.

HORSE FIRM TAKES AUTO AGENCY.

Realizing the great field for the sale of automobiles by a house which has an established reputation, although in a directly opposite line, the Fiss, Doerr & Carroll Horse Company, of New York City, has secured the sole Eastern distribution for Columbus electrics, and a complete line has been placed on exhibition in the salesrooms of the concern on East Twenty-fourth street. It is not stated how this will affect the interest of the company in horses, but it is probable that the equine will not be altogether superseded, at least not for the present.

LOGAN TRUCK PLANT GETS NEW LEASE OF LIFE.

COLUMBUS, O., March 29.—John H. Blacker and Mortimer Renick last week purchased the plant of the Logan Construction Company at Chillicothe, O., at auction. The purchasers announced that they would continue the manufacture of automobiles in the plant. Commercial machines only will be made.

Port Jervis, N. Y.—Alfred Munnich has begun work upon an extension of 100 feet to his garage on Pike street. It is planned to use the present garage as a store and salesroom.

Strang Inspects Indianapolis Speedway Model.

To show the plan of the Indianapolis Motor Speedway, a concrete model has been laid out. There will be a course within a course, so that either a two-and-a-half-mile track or a five-mile track can be used, with space for a balloon starting ground inside.

CATSKILL-BERKSHIRE TOUR OF NEW YORKERS.

Instead of a two-day tour next June, up to Catskill, N. Y., and return, the members of the New York Automobile Trade Association, and their friends, who so enjoyed the novel run to Montauk Point last Fall, will this Summer be given a treat in a tour through the Catskill Mountains and Berkshire Hills.

The route is a beautiful one, and early in the morning of June 12 the machines will assemble and run to Tarrytown, where a special ferry will carry them across the river to Nyack, and then the route will lead them to Arden, in the Highlands of the Ramapo. This is said to equal in scenery the Scottish Trossacks, and a picnic luncheon will be provided. Through Tuxedo the cars will journey, if permission to enter this sacred precinct can be secured, to Kingston, where the night stop will be made. On the following day, June 13, the course will lead through the Catskills to Albany, thence through the Berkshire country to Great Barrington, an all-night stop.

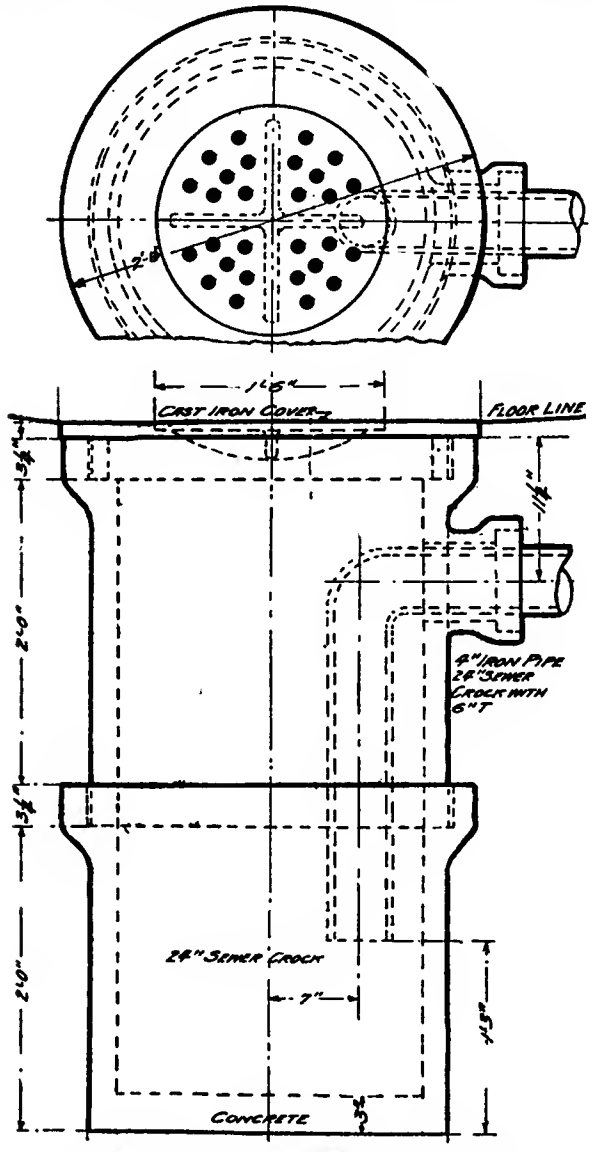
The third part of the run will lead the cars by easy stages through Lakeville and Dover Plains to Paulding for lunch, and in the afternoon through Paterson and White Plains to New York City. The committee in charge is composed of C. P. Skinner, chairman; Harry Fosdick, Richard Newton, Peter Fogarty and Walter R. Lee, manager.

Studebaker Finishing Denver-Chicago Run.

Sent from Denver by the Denver "Post," in the interests of automobilists to have that city upon the Glidden tour route, this car was driven by George Smithson through blizzards, snowdrifts, and long stretches of deep mud, in its hard trip. He was accompanied by W. H. Fairbanks, Jr., who bore the official messages.

PROBLEM OF GARAGE GASOLINE DRAINAGE

THE rapid increase in the use of automobiles using gasoline as fuel requires a solution of a problem which is comparatively new, says *Domestic Engineering*. A careless chauffeur upon running his machine into the garage may fail to shut off the gasoline. This drips on the floor, collects in the drain and may find its way to the sewer. It is a danger to be apprehended, either in the garage, in the floor drain trap or in the sewer, as its exceptionally volatile character permits it to vaporize rapidly at a low temperature, and this vapor coming in contact with a burning match, gas light or an electrical spark may cause an explosion dangerous in character and destructuve in effect.



Sketch of Home Made Safety Drain Pipe.

From the sewer, gasoline may find entrance into house drainage systems, and thus cause damage.

What is the best way to prevent the entrance of gasoline into the sewer and the proper way to care for it in the drainage of the garage? A few samples of what is required in different cities will prove interesting:

W. G. Williamson, inspector of plumbing, Detroit, Mich., recommends the accompanying method of constructing a catch basin in an automobile garage, believing that it will safely care for any accumulation of gasoline and prevent its getting into the sewer. In explaining his plant, Mr. Williamson states that the method he suggests will prove more satisfactory, or at least fully as satisfactory, as more expensive methods of construction. As will be seen by reference to the drawing, the method calls for the use of one section of 24-inch sewer crock set on its spigot end in a bed of three inches of concrete to make a perfectly water-tight base. In the hub end of this two-foot length of sewer crock he places a 24-inch sewer crock with a 6-inch tee, the joint being made of concrete. A 4-inch iron pipe elbow is carried through the 6-inch tee opening of the upper section of the crock, the joint to be made with concrete, and the elbow turning down so that its lower end will come within one foot of the bottom of the catch basin, which ought to provide ample space for sand and settlings so that the basin would not require cleaning too frequently. The seal provided for this elbow is nearly two feet, which should be ample to prevent any gasoline ever getting into the sewer. Whatever gasoline finds its way into this catch basin will be vaporized and the vapor passes through the perforated cast iron cover of the catch basin into the garage, and thus makes the presence of the gasoline known and causes caution on the part of the attendants. The cover of the catch basin as shown consists of a cast iron cover ring with an annular ring which sets into the hub of the upper section of crock pipe and which can be set with concrete, and would probably be best so set, as the ring would remain rigid when wheels passed over it. The removable cast iron cover is perforated with 1-inch holes set in rings 4 inches apart, and this ring is made with ribs on the underside to strengthen it. The entire catch basin is set so that the floor will drain to the perforated cover.

Geo. R. Stolz, inspector of plumbing, Milwaukee, Wis., writes that there is no special way used in his city of taking care of gasoline which might drip from automobiles and find its way into the sewer. He permits the use of an ordinary catch basin with elbow turned down and with its mouth high enough in the catch basin to allow about 2 feet of depth for sand or dirt settlings. Gasoline being of a light specific gravity will gather on top of the contents of the catch basin and be dissipated into the garage through the perforated catch basin cover.

SMOKE ORDINANCE INOPERATIVE ON HILLS.

PHILADELPHIA, March 29.—"On the level" you must not smoke, unless you desire to pay $5 and costs, but you may smoke going uphill without digging into your jeans—such is the dictum promulgated last week by the Park Commission, through Magistrate Harris, who had a score or more of offenders before him at the Ledgely guard house. The rules of the commission make it a finable offense to drive on the Park roads an automobile which "emits offensive quantities of smoke or disagreeable odors," and the gray-coated guards have been busy for the past fortnight keeping tabs on the tag numbers borne by all "smokers." Those who were able to convince the magistrate that they were going uphill at the time were discharged with a warning; the smokers "on the level" were fined the $5 and costs which the statute provides.

It developed during the hearings that the majority of the offenders were demonstrators from the various establishments along "Gasoline Row," who invariably take their "prospects" up and down Sweet Briar and Tam o'Shanter hills a few times to show off their cars' abilities in the hill climbing line.

AUTOISTS WAR ON WATERBREAKS.

WASHINGTON, D. C., March 29.—The Automobile Club of Washington has started a vigorous campaign against waterbreaks, which abound in all the roads leading out of the capital city. A committee, consisting of Robert B. Caverly, A. Ward Evans and Fulton R. Gordon has been appointed to deal with this subject and are receiving enthusiastic support.

A Bevy of Pretty Girls in an Anderson Electric.

CHICAGO TRADESMEN ELECT TOM HAY.

CHICAGO, March 27.—The annual election of the Chicago Automobile Trade Association resulted in a victory for the member's party, which put into office all its candidates with the exception of one, the successful slate being made up as follows: President, Thomas J. Hay; vice-president, Joseph F. Gunther; secretary, F. E. Sparks; treasurer, Henry Paulman; directors, N. H. Van Sicklen, A. J. Banta and H. P. Branstetter.

DUCASSE GETS DARRACQ AMERICAN AGENCY.

With the whole United States as territory, Henry Ducasse & Company, located at 140 West Forty-second street, New York City, has secured the American agency for Darracq cars, controlling not only the importation and sale of touring cars and chassis, but also of taxicabs. By the terms of the agreement with A. Darracq & Company, of Suresnes, France, the new agents will make large importations, and sub-agents started in all of the large cities.

CHALMERS NAMES QUALITIES FOR SALESMEN.

DETROIT, March 29.—Hugh Chalmers, president of the Chalmers-Detroit Motor Company, recently addressed the Detroit Adcraft Club at its noonday luncheon, on "The Relationship of Salesmanship to Advertising." Asserting that there are ten essential qualities in successful salesmanship—health, honesty, ability, initiative, tact, sincerity, industry, knowledge of the business, open-mindedness, and enthusiasm—he declared that nine out of ten of these qualities had to do with the man himself. "Salesmanship is nine-tenths man and one-tenth goods and territory," said Mr. Chalmers.

NEW JERSEY TRADESMEN RE-ELECT OFFICERS.

NEWARK, N. J., March 29.—At the annual meeting and banquet of the New Jersey Automobile Trade Association, last Thursday evening, the officers who have guided the association so well during the year just closed were re-elected. The gathering was the largest and most successful yet held, and was productive of much good toward strengthening the organization. The officers re-elected were: George Paddock, president; J. W. Mason, vice-president; W. H. Ellis, secretary; R. A. Greene, treasurer. F. L. C. Martin and L. B. Zusi were elected members of the executive committee for three years.

PROPOSED TOLEDO DEAL OFF; ANOTHER PLAN.

TOLEDO, O., March 27.—After the Apperson deal for the Pope Motor Car Company has progressed so far as to name this year's cars Apperson-Toledo, announcement has just been made by Henry L. Thompson, of this city, that the deal is off and that another was being considered. When Mr. Apperson took an option on the local plant, one of the conditions was that $250,000 be put into the plant by Toledoans. The option taken at that time expired a week ago, but was extended till March 27, and now Mr. Thompson, who has been in charge of raising the $250,000, says that the deal is off for the present and that another proposition whereby the plant may be retained in this city is being considered. Just why the deal fell through is not made public.

Receivers A. L. Pope and George A. Yule have been discharged as receivers for the local plant, although they are yet under a nominal bond of $20,000.

COMMERCIAL VEHICLE FACTORY AT ANN ARBOR.

ANN ARBOR, MICH., March 29.—Under the name of the Triple Motor Truck Company, a new concern, capitalized at $340,000, is about to close with local business men for the establishment here of a large plant to manufacture commercial motor vehicles. F. O. Paige of Detroit, Andrew Bachle and H. A. Wilcox of Owosso, formerly connected with the Reliance Motor Company of Flint, are named as the principals in the negotiations.

ANOTHER AUTO BUGGY FACTORY PLANNED.

TOLEDO, O., March 27.—The Auto-Bug Company, of Norwalk, O., has just been incorporated with a capital stock of $100,000, and will manufacture high-wheeled auto buggies and other motor vehicles. Incorporators are: I. W. Goodell A. E. Skadden, C. F. Jackson, J. R. McKnight and W. G. Gilger. It is the intention of the concern to occupy an unoccupied factory building for the present, but an entirely new structure will be built within a year.

Renault in Front of the Coliseum at Rome.

News in General

A London Bus Feeling Its Way Through Flooded Streets.

Bursting water mains in the city of London recently made street traffic impossible for all but motor vehicles. The 'buses pushed their way through thoroughfares wheel-deep with water, that was filled with wooden paving blocks and other obstructions, and carried passengers to and from their homes in safety.

Cadillac Company Gives a Banquet.—To celebrate the arrival in this country of the famous Dewar trophy the Cadillac Motor Car Company a few evenings ago tendered a banquet to about eighty of its employees, composed mainly of heads of the mechanical departments, at the Hotel Ponchartrain, Detroit. The celebrated cup occupied the center of the table, the first time that it has been won by an American concern. It is one of the most coveted trophies in Europe, because it is awarded each year by the Royal Automobile Club to the manufacturer accomplishing the most noteworthy performance toward the advancement of the industry, and was given to the Cadillac because of its remarkable standardization test at Brooklands track last year. At that time three single-cylinder Cadillacs were selected at random, disassembled, their parts intermingled, 89 withdrawn and substituted for by extra parts from the stock supply, and when they were reassembled the machines were taken right out on the track and run 500 miles without any trouble. The dinner was given by the management of the concern to thank and commend the heads of the departments who made this possible. Among the guests was W. R. Warner, of Cleveland.

Meeting of Engineering Societies.—On Tuesday, April 13, will be held the presentation of the John Fritz medal for 1909 by the four national engineering societies, A.S.M.E., A.S.C.E., A.I.E.E. and A.I.M.E. The board of award, especially chosen for the purpose, has selected Charles T. Porter, honorary member A.S.M.E., as the recipient of the honor, for his work in advancing the knowledge of steam engineering and in improvements in steam engine construction. Besides the simple ritual of the presentation of the medal, there will be addresses by representatives of the four groups of the profession most concerned. Attendance is not restricted to the members, but the public is cordially invited.

Automobile Factories Wanted.—Watertown, N. Y., in a little booklet which has been sent out to automobile manufacturers, is calling attention to its facilities as the situation for an automobile factory, with water power, railroad sidings, and established industries which are closely allied with the automobile. These are body building plants, spring makers, builders of gas and gasoline engines, copper and nickel plating plants, and many others. Loren R. Johnston is a moving spirit in seeking for new industries, and invites any one interested to communicate with him.

Hartford Rubber Works Officers Change Positions.—At a meeting of the board of directors of the Hartford Rubber Works Company, held in Hartford, J. P. Krogh, chief of the credit department, was elected treasurer to fill the vacancy caused by the resignation of Henry F. Plow, who has accepted a position with the Mitchell Motor Car Company. D. W. Pinney was elected assistant treasurer, and Franklin Kesser, sales manager, and former manager of the Philadelphia branch of the company, was elected assistant secretary. The office of secretary was left vacant.

Farmers Are Converts to the Automobile.—So great is the interest taken in the automobile in Michigan, particularly by the agriculturalists, that the State Agricultural College proposes to establish a course and give instructions in its general uses and adaptability. This will be a short winter course and the students will be taught the structure and operation of engines as well as dismantling and assembling of cars. When they have mastered this, they will be taught to drive. It is said that the State schools of Iowa and Kansas will follow suit and establish similar courses.

Rambler Spare Wheel Contests.—Keen rivalry has arisen among owners of and dealers in Rambler cars to lower records of the time needed to substitute the spare wheels for the regular ones. At present the record is held by one of the mechanics of the Cleveland agent, who changed one wheel in fifty-nine seconds, first jacking up the car and letting it down after completing the operation. All four wheels were changed in four minutes and a half. W. K. Cowan, of Los Angeles, claims 1:45 as his record time, while a novice in that city made the change in 2:50.

Selden Car as Gift to a Prelate.—As a mark of high esteem and regard, on the occasion of the 25th anniversary of his ordination, Rt. Rev. Thomas F. Hickey, D.D., of Rochester, N. Y., was presented with a Selden touring car by his parishioners. His duties call him over a wide area of the country surrounding the city, and for this reason the practicability of such a gift was appreciated by those who gave it. At the presentation a copy of the New York State automobile law was also given to the prelate, much to the general amusement.

Statistics of Goodyear Detachable Rims.—The Goodyear Tire & Rubber Company, to show the growth of the popularity of quick detachable rims, has compiled statistics, taking as a basis the fourteen automobile shows held in the principal cities of this country since the opening of the Palace show, New York City, January 1. There have been on exhibition 1,885 automobiles, and of these 1,371, or 72.73 per cent., were equipped with quick detachable rims. The Goodyear quick detachable rim led in eleven out of the fourteen shows.

Making a Bigger Jewel.—The Jewel Motor Car Company, located at Massillon, O., has found the present factory space so much too small for the amount of work being done that an addition has become a necessity. As now planned, this will be 55 by 80 feet and two stories high with a saw tooth roof. This increase in the plant has not only been planned, but work has actually commenced on it. When this work is completed it is expected that 250 men will be employed.

Fisk Tires on Fire Apparatus.—Success in equipping automobile fire apparatus with Fisk tires in the past has influenced the Fisk Company to give especial attention to this branch of the trade, and recently the Fisk tires have been adopted as equipment by the Robinson Fire Apparatus Manufacturing Company, of St. Louis, and the La France Engine Company, of Elmira, N. Y. The pneumatic bolted-on type has been popular, as well as solid tires.

New York Carnival Prizes. — The plans for the automobile carnival week of the New York Automobile Trade Association are fast being put into shape, and it has been decided that the $2,000 to be given as prizes for the cars in the parade shall be divided into $500, $250 and $150 for decorated pleasure vehicles; $500, $200 and $100 for the decorated floats or displays, and $200 and $100 for grotesquely decorated cars.

Holsman Factory Running at Night.—According to the Holsman Automobile Company, this year will be a record breaker in the amount of business done in high-wheeled automobiles, for already the pressure of demand has been felt. The Holsman factory in Chicago is now working at night as well as day and is still behind orders. The demand for the 1909 cars with direct drive from the motor to the wheels is very great.

New Factory for Rothschild & Company.—An old four-story building at the corner of Eleventh avenue and Fifty-seventh street, New York City, has been purchased by Rothschild & Company, and will be altered from a flax mill into a thoroughly renovated automobile fac-

tory. The building is a large one, 200 by 167.8 feet, with a frontage of 100 feet upon Fifty-sixth street.

New Navy Secretary Buys a Waverly.—The new administration at Washington is showing interest in the automobile industry. Following the conversion of the White House stables into a garage and the purchase of touring cars for the President, the new Secretary of the Navy, George Von L. Meyer, has purchased a Waverly Victoria phaeton for his personal use.

Arseno Electric Company Opens Boston Store.—The Arseno Electric Company, wholesale and retail dealers in electric and automobile equipment, has established a store at 819a Boylston street, where it will make its headquarters. C. B. Arseno, the manager, has had 25 years' experience in the electrical field and 18 in the bicycle and automobile work.

McCue Moves into New Factory.—The McCue Company, builders of the McCue Hartford car, are now moving into their new factory on Pliny street, Hartford, Conn. The building is two stories high, and will give facilities for a much increased output.

Minneapolis Car's Name Changed.—The H. E. Wilcox Motor Car Company of Minneapolis, which has been manufacturing the Wolfe touring cars and trucks for the last four years, has announced that hereafter the name of its product will be called the "Wilcox."

IN AND ABOUT THE AGENCIES.

Fisk Tires: Philadelphia.—Upon the completion of extensive alterations to the new building at 258 North Broad street, the Philadelphia branch of the Fisk Rubber Company, under the management of K. B. Harwood, will move from its present quarters at 1309 Race street.

Dow Tire Company Has Boston Branch.—The Dow Tire Company has opened a branch in Boston at 889 Boylston street, where it will handle all of the New England trade to dealers, as well as the retail trade.

Crawford, Philadelphia.—The Philadelphia agency for the Crawford has been taken over by the Crawford Automobile Company, of Philadelphia, with headquarters at Broad and Ridge avenue, under the management of Henry R. Hoopes.

Knapp-Greenwood Company Opens Salesroom.—The Knapp-Greenwood Company, manufacturer of shock absorbers, with a factory at Farmington, Me., has established a salesroom at 998 Boylston street, Boston.

KisselKar: Philadelphia.—Rogers & DuBois, owners of the Rittenhouse Motor Company, at 214-220 South Twenty-third street, have been awarded the Philadelphia agency for this car.

Lozier: Northern California.—S. G. Rayl, distributor, with headquarters at the Broadway garage, San Francisco.

Lozier: Milwaukee, Wis.—Williard V. B. Campbell, Farwell avenue and Brady street, State agent.

Locomobile: Hartford, Conn.—L. D. Fisk, Hartford Automobile Station, 43 Wells street.

Moon: Milwaukee, Wis.—Riverview Automobile Company, 325 E. North avenue.

Velie: Kansas City.—Evans Automobile Company, 1927-1929 Grand avenue.

TAXICABS AND TRANSIT.

Hartford, Conn.—The Capital City Auto Hack and Livery Company, local agent for the Mitchell, will start a line of taxicabs shortly. This will make three different lines in this city, the Maxwell, which is doing well, and the Elmore, inaugurated about a week ago with satisfactory results, and the Mitchell. The local public seems to be losing the idea that a taxicab costs a fortune. Considerable trade is picked up at the local hotels, and both the Elmore and the Maxwell make headquarters at a garage. When the Maxwell was first started it was put on the public vehicle stand, but was later withdrawn and put in the garage. The Elmore has been kept busy and has not had time to be on the public service stand more than three times.

Long Auto Line in Texas.—Road work has now been completed upon the extension of the automobile stage line from Seminole, Tex., to Carlsbad, N. M., so that now the total length of the line from Midland, Tex., to Carlsbad is 240 miles. Merchants of the latter place have offered a bonus if the schedule is fixed and maintained at ten hours. This is said to be the longest automobile line.

New Line to Yellowstone Park.—Orders for several Mason cars, made in Des Moines, Ia., have been placed by the Wyoming Transit Company, Inc., for use in service between Rock Springs, Wyo., and the Yellowstone Park, to make trips of 100 miles daily on a regular schedule.

Traverse City, Mich.—A rapid transit company has been given a license to operate an automobile 'bus line in this city on a regular schedule and a five-cent fare. During the Summer months the service will be extended to the resorts.

North Birmingham, Ala.—This city has just received its new automobile fire engine. The machine arrived lately and after a satisfactory public demonstration by Chief Bennett was permanently located at the central fire station.

Ilion, N. Y.—A motor 'bus company is arranging to establish a regular automobile service covering Otsego street, West hill, Barringer and Armory hill.

RECENT BUSINESS TROUBLES.

Missouri Valley Auto Co., Kansas City, Mo.—Harvey E. Rooklidge, president of the Missouri Valley Auto Company, 1112-1114 East 15th street, Kansas City, Mo., has made application for a receiver for the company.

RECENT BUSINESS CHANGES.

Stromberg Branches Move.—The New York branch of the Stromberg Motor Devices Company will move about April 1 to the new Automobile Building at Broadway and Sixty-fourth street, where offices will be combined with the installation department. The San Francisco branch has been moved to 307 Golden Gate avenue from its former location at 426-428 Van Ness avenue.

Hess-Bright Manufacturing Company, New York.—The New York office of the Hess-Bright Manufacturing Company has been moved from 90 West street to 1974 Broadway, where a store has been opened to carry complete lines of HB-DWF ball bearings and Hess-Bright magnetos. George T. Gwilliam is the resident manager.

New York Knox Branch Will Move.—The Knox Automobile Company has leased the salesroom at 1966 and 1968 Broadway, New York City, formerly occupied by the S. P. O., and its metropolitan branch, under the management of H. M. Davis, will move into it on May 1.

Hayes Mfg. Company to Enlarge.—The Hayes Manufacturing Company of Detroit, manufacturers of automobile sheet metal parts and forgings, has found it necessary to erect an addition to its plant on Maybury avenue.

PERSONAL TRADE MENTION.

Irving J. Morse, until recently the manager of the Philadelphia branch of the Locomobile Company of America, has received a promotion in being assigned to the management of the San Francisco branch of the Locomobile Company, having in charge not only all of the business in the Western and Coast States, but also of the export business to Japan and Hawaii. Philadelphia automobilists gave him an enthusiastic send-off, expressing at luncheons their regret at losing him, but congratulating him upon his enlarged work. Mr. Morse's successor is S. de B. Keim, who has been connected with the Locomobile Company for nine years in various capacities.

P. K. Larter, for many years a prominent feature in New York automobile circles, and well known as a driver of Mercedes and Renault cars, has become identified with the Allen Auto Specialty Company, of 1926 Broadway, N. Y., makers of Allen tire covers, as Eastern traveling representative.

W. A. Woods, formerly general manager and treasurer of the Cleveland

First Holsmans Take Part in Family Reunion.

Four of the first cars made by the Holsman Automobile Company recently took an active part in a family reunion at Spirit Lake, N. D. The cars are owned by the family of A. P. Halstead and traveled distances varying from 20 to 100 miles for the gathering. They are over six years old and still in service.

Motor Car Company, of Cleveland, O., has joined the staff of Manager William B. Hurlburt, of the New York branch of the E. R. Thomas Motor Company.

William W. Taxis, who has been connected for several years with the White Company, has been appointed assistant sales manager in the East to assist George W. Bennett, the Eastern sales manager.

Henry Plow, secretary and treasurer of the Hartford Rubber Works Company, has resigned, to take effect on April 15. He will then become the assistant treasurer of the Mitchell Motor Car Company.

C. S. Bugbee has been appointed district sales manager for the City of Detroit by the Rapid Motor Vehicle Company, with salesrooms located at 467 and 469 Woodward avenue.

Peter Fogarty has re-entered the metropolitan sales business as sales manager for George C. John, who now handles the American Mors, the Marmon and the Interstate.

John H. Rosen has been appointed general manager of the Autolight and Motor Supply Company, Inc., Broad street, above Spring Garden, Philadelphia.

STEWART & CLARK EXPANDING.

Owing to the vast increase in its speedometer business, the Stewart & Clark Manufacturing Company, of Chicago, has found it necessary to constantly expand its manufacturing facilities. The illustration shows the company's plant as it appears to-day, a new addition having just been completed and occupied. This recent addition, although large in extent, must be followed shortly by another still larger. The company reports an unprecedented demand for all the models of the Stewart line, including those recently added and shown at the recent New York and Chicago shows.

Factory of Stewart & Clark Mfg. Co.

SPIRAL SPRING PATENTS.

"Supplementary Spiral Springs," made by the Supplementary Spiral Spring Company of St. Louis, will hereafter be sold exclusively to the trade, as well as retail, by the St. Louis Supplementary Spiral Spring Company, Inc., of New York. The latter concern has just been incorporated, and has established its offices in the Motor Mart Building, 1876 Broadway. It will take the entire production of the St. Louis factory. William Young is the president of the firm.

By an injunction restraining Graham's Automobile Spring and Appliance Company of Boston from imitating in any way the product of the St. Louis Supplementary Spiral Spring Company, Inc., the latter has won a victory in a long suit for infringement of its patents, and gives it the patent rights in the manufacture of its shock absorbing springs.

RECENT INCORPORATIONS.

Herring-Curtis Company, Hammondsport, N. Y.—Capital, $360,000. To manufacture motore, motorcycles, boats, vehicles, balloons and flying machines. Incorporators: A. W. Gilbert, Brooklyn, N. Y.; Chas. Heitman, Forest Park, N. Y.; W. B. Denton, New York City.

Mason-Seaman Transportation Company, New York City.—Capital stock, $500,000; will run a livery and boarding etable, automobile passenger and baggage transfer. Incorporators: Henry Schwed, Wm. H. Corbitt, Arthur Frank and John J. Harris.

Welch-Forrester Company, New York City.—Capital stock, $25,000; will manufacture motors, vehicles, engines and machinery. Incorporators: A. R. Welch, Pontiac, Mich.; Allen P. Hallett and Mark M. Solomon, New York City.

Munsing Motor Car Company, Hoboken, N. J.—Capital stock, $1,000,000; will manufacture automobiles, motors, engines and trucks. Incorporators: W. H. Buresmith, J. B. Franklin and C. H. Bellowe, Jr.

Dart Engineering Company, New York.—Capital, $10,000. To manufacture automobiles. auto cars, motorcycles. Incorporatore: J. R. Del Rio, New York; G. C. Autenrieth, Westchester; P. S. Tice, Brooklyn.

Cordner Motor Car Company, New York.—Capital, $25,000. To manufacture, lease and sell horseless vehicles. Incorporators: A. B. Cordner, Robt. E. Graham and W. H. Flinn, Broadway and 76th street.

Wonder Manufacturing Company, Syracuse, N. Y.—Capital stock, $40,000; will manufacture motor boats and automobiles. Incorporators: William D. Boyle, George T. Hurd and Bertha C. Cornwell.

Valley Boat and Engine Company, Baldwinsville, N. Y.—Capital stock, $20,000; will manufacture gasoline motors and engines. Incorporators: D. S. Simpson, R. H. Hubbell and J. Talimadge.

Auto-Car Manufacturing Company, Buffalo, N. Y.—Capital stock, $250,000; will manufacture automobiles, motor vehicles. Incorporators: John B. Pierce, G. W. Atterbury and G. D. Pratt.

Barnes-Curtiss Company, Inc., New York City.—Capital stock, $25,000; will manufacture, rent and deal in automobiles. Incorporators: H. B. Barnes, Jr., A. L. Curtiss, New York City.

Premier Motor Car Company, Chicago.—Capital, $12,000. To manufacture automobiles and accessories, 100 Washington street. Incorporators: Webb Jay, W. E. Stalnaker, Robt. Eveland.

Connecticut Motor Vehicle Company, New York City.—Capital stock, $50,000; will manufacture motors, engines and machinery. Incorporators: C. M. Gilpin, H. A. Shuart and H. C. Murray.

Reliable Auto Company, Ayer, Mass.—Capital stock, $25,000; will do a general automobile business. F. H. Williame ie the president and W. L. Preble le also interested.

Robart-Carleton Company, Boston, Mass.—Capital stock, $45,000; will deal in fire wagons, police ambulances, etc. Incorporators: O. M. Carleton and Albert Robart.

American Auto Appliance Company, Chicago.—Capital, $200,000. To manufacture and deal in vehicles. Incorporators: E. A. Garvey, C. A. Garvey and F. R. Belt.

Bilbro Auto Company, New York City.—Capital stock, $20,000; will manufacture autos and maintain a garage. Incorporators: J. E. Troy, W. L. Brown and E. Mayer.

Consolidated Rubber Company, New Haven, Conn.—Capital stock, $250,000; will deal in rubber, rubber products or stock and properties of similar companies.

Louis Geyler Company, Chicago.—Capital stock, $50,000; will manufacture automobiles and accessories. Incorporators: L. Geyler, L. R. Geyler and J. L. McNab.

Bendix Company, Oak Park, Ill.—Capital, $200,000. South Dakota corporation. To manufacture automobiles and accessories, 423 South Humphrey avenue.

Badger Four-Wheel Drive Auto Compsny, Clintonville, Wis.—Capital stock, $45,000. Incorporators: Otto Zanchow, W. A. Benedict and W. H. Finney.

Wadhams Oil Company, Milwaukee.—Increase in capital stock from $350,000 to $500,000; will enter the automobile field with automatic tanks.

White Star Automobile Company, Atlanta, Ga.—Capital stock, $150,000. Incorporators: Clarence Houston, Harry W. Anderson and Frank J. Long.

Pioneer Automobile Exchange, Los Angeles, Cal.—Capital stock, $25,000. Incorporators: J. W. Mitchell, F. E. Edwards, H. F. Duck and R. E. Moir.

SELECTED AUTO PATENTS.

Issue of March 23, 1909.

915,733. Motor Vehicle with Three Axles.—Auguste E. Brillié, Parie, France, assignor to Société Anonyme dee Automobiles Eugene Brillié, Paris, France. Filed Nov. 7, 1907.

915,769.—Motor Vehicle.—Russell Huff, Detroit, Mich., aseignor to Packard Motor Car Company, Detroit, Mich. Filed May 18, 1908.

915,825. Differential Mechanism.—Bluford W. Brockett, Cleveland, O., assignor, by mesne aesignments, to Ross Gear & Tool Company, Lafayette, Ind. Filed Nov. 29, 1905.

915,828. Rotary Engine.—Everett S. Cameron and Forrest F. Cameron, Brockton, Maes. Filed April 14, 1908.

915,839. Attachment for Tire Treads.—Frank A. Fox, New York City, assignor to Fox Metallic Tire Belt Company, New York City. Filed Sept. 9, 1908.

915,840. Tire Tread Attachment.—Frank A. Fox, New York City, assignor to Fox Metallic Tire Belt Company, New York City. Filed Sept. 12, 1908.

915,841. Attachment for Tire Treads.—Frank A. Fox, New York City, aseignor to Fox Metallic Tire Belt Company, New York City. Filed Oct. 9, 1908.

915,842. Attachment for Tire Treads.—Frank A. Fox, New York City, assignor to Fox Metallic Tire Belt Company, New York City. Filed Oct. 10, 1908.

915,843. Antiskid Device for Tires.—Frank A. Fox, New York City, assignor to Fox Metallic Tire Belt Company, New York City. Filed Oct. 24, 1908.

915,891. Spark Timer for Internal-Combuation Engines.—Henry Schaake and John T. Cowie, New Westminster, British Columbia, Canada. Filed Feb. 7, 1908.

915,920. Rear Axle Driving Mechaniam for Automobiles.—Alexander Winton and Harold B. Anderson, Cleveland, O., assignors to Winton Motor Carriage Company, Cleveland, O. Filed Sept. 7, 1905.

915,954. Pneumatic Tire Mounting.—Charles G. Hawley and Erie K. Baker, Chicago. Filed April 11, 1908.

915,976. Route Indicator for Automobiles.—Frank D. Lindenthaler, Glens Falls, and John Protz, New York City. Filed Nov. 30, 1907.

916,032. Universal Shaft Coupling.—Charles Schmidt, Cleveland, assignor to Peerless Motor Car Company, Cleveland. Filed Jan. 2, 1909.

916,073. Starting Device for Internal Combustion Engines.—Arthur C. Wells, Amityville, N. Y. Filed Oct. 7, 1908.

916,086. Friction Clutch.—Albert N. Woods, Corvallis, Ore. Filed Feb. 4, 1908.

916,103. Carbureter for Explosive Engines.—David J. Cartwright, Boston. Filed Dec. 5, 1904.

916,118. Hub for Automobile Wheels.—Alfred A. De Mars, Lakewood, O., assignor of one-half to Harry Coulby, Lakewood, O. Filed Aug. 25, 1906.

916,214. Controller for Carbureters.—Alfred C. Stewart, Los Angeles, Cal. Filed April 27, 1908.

916,224. Motor Vehicle Drive Gear.—Waid H. Thomas, Taylor, N. D. Filed Dec. 21, 1908.

916,296.—Starting Mechanism for Internal Combustion Engines.—Edward C. Gentzler, Columbus Junction, Iowa. Filed Jan. 5, 1909.

916,312.—Ignition Gear for Internal Combustion Engines.—Rudolf, Zweibrucken, Germany. Filed March 3, 1904.

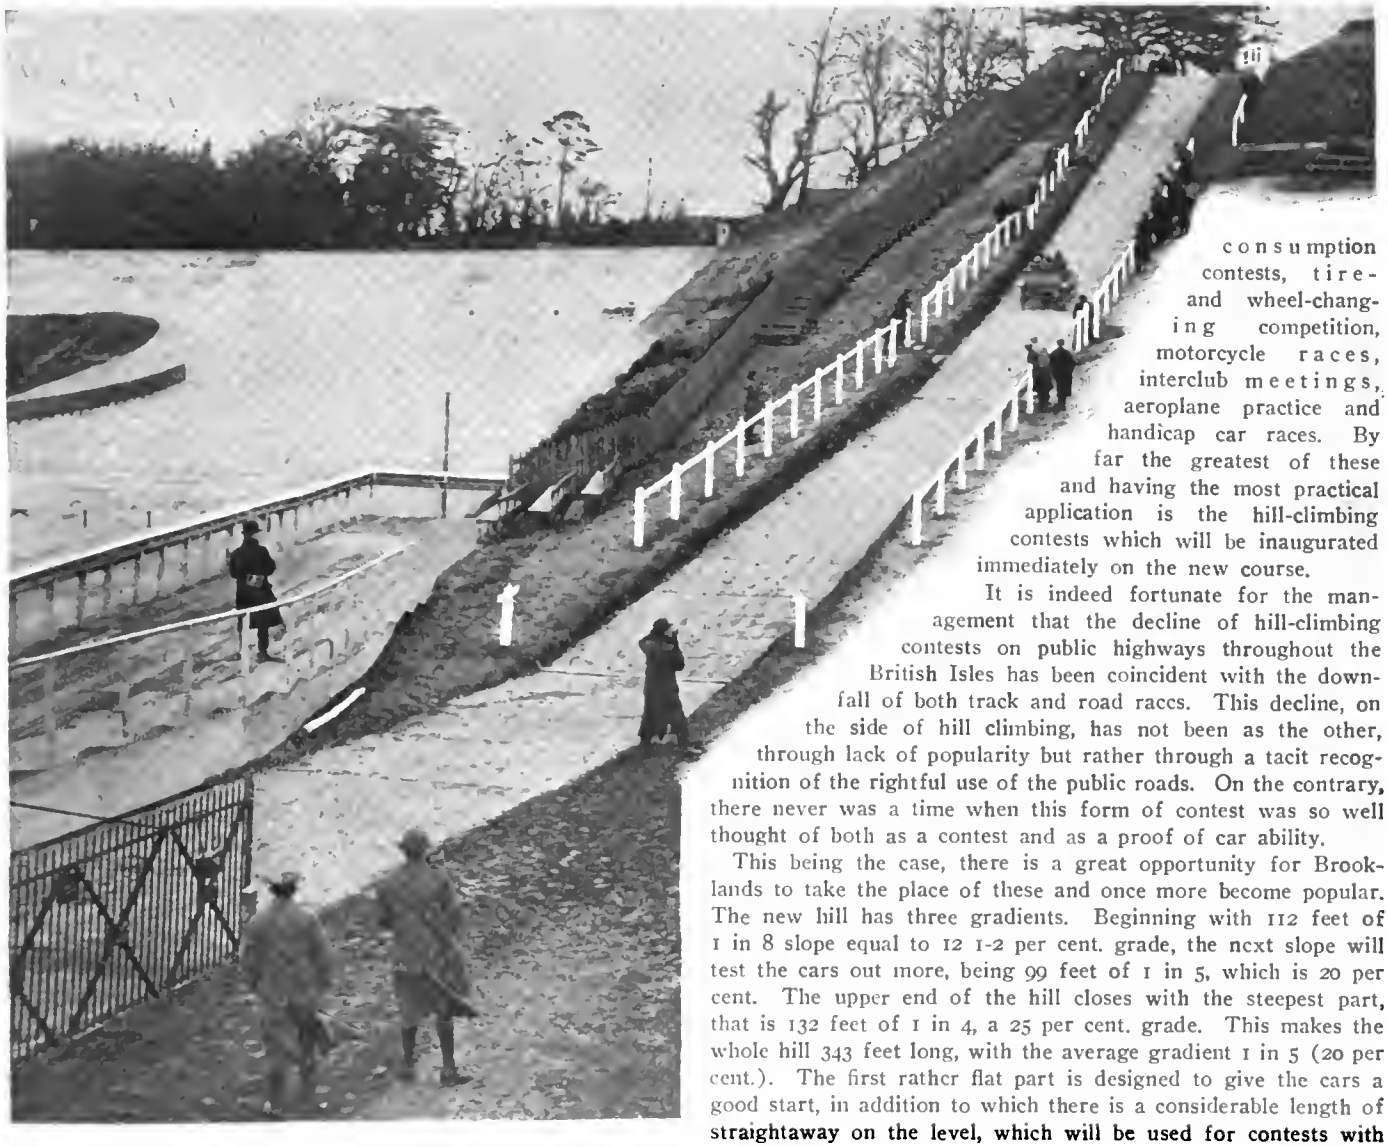
916,313.—Spark Plug.—A. W. S. Herrington, Madison, N. J. Filed May 7, 1908.

916,390. Terminal Connector.—Charles Cuno, Meriden, Conn., assignor to Connecticut Auto Engineering Corporation, Meriden, Conn. Filed March 28, 1908.

Vol. XX New York—Thursday, April 8, 1909—Chicago No. 14

THE AUTOMOBILE

BROOKLANDS NOW HAS A HILL TO CLIMB



LONDON, April 2.—Brooklands, the famous English automobile race course, in which thousands of dollars have been invested, is making another important bid for support, which means another effort to insure some sort of return to the stockholders. A special course has been laid out up the hill in front of the clubhouse, and its already incessant use indicates its attractive value, especially to the man who drives his own car and wants to know what it can do actually.

There have been, and now are, many other plans for popularizing this great but unprofitable enterprise, including fuel-consumption contests, tire- and wheel-changing competition, motorcycle races, interclub meetings, aeroplane practice and handicap car races. By far the greatest of these and having the most practical application is the hill-climbing contests which will be inaugurated immediately on the new course.

It is indeed fortunate for the management that the decline of hill-climbing contests on public highways throughout the British Isles has been coincident with the downfall of both track and road races. This decline, on the side of hill climbing, has not been as the other, through lack of popularity but rather through a tacit recognition of the rightful use of the public roads. On the contrary, there never was a time when this form of contest was so well thought of both as a contest and as a proof of car ability.

This being the case, there is a great opportunity for Brooklands to take the place of these and once more become popular. The new hill has three gradients. Beginning with 112 feet of 1 in 8 slope equal to 12 1-2 per cent. grade, the next slope will test the cars out more, being 99 feet of 1 in 5, which is 20 per cent. The upper end of the hill closes with the steepest part, that is 132 feet of 1 in 4, a 25 per cent. grade. This makes the whole hill 343 feet long, with the average gradient 1 in 5 (20 per cent.). The first rather flat part is designed to give the cars a good start, in addition to which there is a considerable length of straightaway on the level, which will be used for contests with a flying start. Thus high and low gear can be reckoned with in contests.

Above the flat lower part of the grade increases as the upper end is approached until the final part is the steepest of all. Beyond the top there is a slight bend and then the course leads past the grand stand in the general direction of one of the bridges over the main track. All this allows of unlimited speed on the hill with prospects of being able to run beyond.

For testing purposes this will be ideal and the time will doubtless come when this famous place will lose its identity as a race

course and become the national testing grounds, all kinds of tests being provided instead of the single-speed opportunity of the past and the dual idea of speed and hill climbing of to-day. When this comes to pass certificates will probably be issued which set forth the ability of the car under test. According as the track management acts wisely or otherwisely these certificates will have a very real value. In fact, viewed in this light, it is not hard to imagine the average Englishman, ignorant of automobile mechanism, buying on basis of a Brooklands certificate.

The surface of the hill, like the main track, is of concrete about 6 inches thick. On either side are banks of turf 2 feet wide and about 3 feet high, on top of which is a hand rail some 2 feet high. This puts possible spectators quite a distance away from the track and far enough above the cars competing to counteract this. By this arrangement those looking on are in a position to see well without any danger to themselves should the railing give way. The width of the concrete surface is 12 feet, cambered at the center about 2 inches.

The timing arrangements provide for electrical timing at the foot and at the end of each strip of the hill so that total time and individual time on any one part may be taken.

The hill idea took hold very rapidly, only having been proposed the latter part of January. The manager of the track took to it at once, secured the necessary money and proceeded with the construction with all speed. The result is that the hill, conceived less than 10 weeks ago, is now a reality.

One of the minor problems of construction was to lay the concrete in such a manner as to prevent it from flowing both when laid and under the severe work which the use of it entails. This was effected by the use of very heavy cross timbers of oak, which were themselves set in concrete, the latter being in cross trenches some 3 feet deep. Above these timbers come the main ties and finally smaller wooden slats which act as spacers. The concrete foundations fill in between the ties and just cover them. Then there is the top dressing formed of very fine concrete with small granite chips imbedded in it to provide the "hold" necessary on a gradient as steep as this one.

STEAM SCORED BEST IN 'FRISCO CLIMB.

San Francisco, March 29.—The initial event of the San Francisco Motor Club, held yesterday, was a hill climb up what is known as Nineteenth Avenue Street Hill, which has a 6 per cent. grade. The course was a mile long, and the cars were sent away with a standing start. The event also brought out a new timing apparatus designed by a local autoist. This worked perfectly, and made it possible to pull off the whole programme in two hours. The record for the hill went to the White steamer, which climbed in 1:12 2/5.

The fastest time made by a gasoline car was that of the Comet, the California built car, which covered the mile in 1:15 1/5.

CARS COSTING $1,200 OR LESS.

1. Buick "White Streak"	Frank Murray	1:24 4-5
2. Mitchell	A. E. Hunter	1:35
3. Auburn	G. C. Murray	2:00 2-5

SPECIAL MATCH RACE BETWEEN $2,000 WHITE STEAMER AND $1,580 STODDARD-DAYTON.

0. White	1:12 2-5
0. Stoddard-Dayton	Did not finish

(Declared no contest by judges.)

CARS COSTING MORE THAN $1,800 AND LESS THAN $3,000.

1. Thomas "40"	I. L. de Jongh	1:21 2-5
2. Buick	C. S. Howard	1:25 2-5
3. Comet	Frank Free	1:26 1-5

CARS COSTING MORE THAN $3,000.

1. Stearns	D. A. Bonney	1:20
2. Pope-Hartford	Jack Fleming	1:20 2-5
3. Palmer & Singer	C. Onthank	1:23 3-5

CARS COSTING OVER $1,200 AND LESS THAN $1,800.

1. Stoddard-Dayton	Fred J. Wiseman	1:20
2. Oakland	W. W. McDonald	1:40 2-5
3. Overland	Bob Fowler	1:54 4-5

FREE-FOR-ALL.

1. Stanley Steamer	O. C. Joslyn	1:13 3-5
2. Comet	Frank Free	1:15 1-5
3. White Steamer	Gus Seyfried	1:16 1-5
4. Stearns	D. A. Bonney	1:18 1-5
5. Stoddard-Dayton	Fred Wiseman	1:19
6. Pope-Hartford	Jack Fleming	1:20
7. Palmer & Singer	C. Onthank	1:23 2-5
8. Acme "Six"	Fay Sheets	1:24 4-5
9. Buick	Frank Murray	1:25 3-5
10. Rambler	L. B. Harvey	1:31 3-5
11. Mitchell	A. E. Hunter	1:32 3-5

Looking Down from the Top of the Brooklands Hill During a Recent Private Test of Its Grades.

Indiana's Speedway Rapidly Becoming a Reality

INDIANAPOLIS, IND., April 5.—Active work in building the Indianapolis Motor Speedway has been commenced by the contractors and carpenters, and in a very short time it is expected that the fifty feet wide course will be completed. The contractor in charge of the grading has on the scene machines which gather and dump a wagon load of dirt every half minute, with the scrapers, scoops, rollers, traction engine, and wagons necessary to do the work. The track will be sixty feet wide on the banked turns. The carpenters are busy building the fence, and the buildings, and a uniform color scheme has been decided upon for their finish. A view of green, trimmed with white will greet the visitors next Summer. A club house and a two-story restaurant are expected to be completed by June 1.

There are 328 acres in the enclosure, and the first plan of having two courses, one within the other, the outside one three miles long, and the inside one two, giving a five-mile course by using them combined, has been changed. The new plans call for an outside track of two and a half miles with curves that will permit a speed of 105 to 112 miles an hour, and the inside course is the same length, so that together the five miles can be secured. Under the present arrangement the cars will pass the grand stand three times on one lap, and it will be possible to see all of the contestants all of the time, at any part of the course.

The Indianapolis Gas Company will soon have a pipe line laid to the space for filling balloons, and in ample time for practice for the international race of the Aero Club of America, which starts on June 5. G. L. Bumbaugh, aeronautical captain of the Aero Club of Indiana, returned from the West this week to accompany Indianapolis balloonists in their flights necessary to become pilots in the national club.

ST. LOUIS PLANS CONCRETE RACE COURSE.

ST. LOUIS, April 5.—A project to build a reinforced concrete automobile race course and balloon ascension grounds has been started by the Million Population Club of this city, and has made rapid and substantial progress. The track will be oval and two miles in length, with the ascension grounds in the center, and a grand stand will be erected to accommodate 10,000 people. The Missouri senators have become members, and a large number of wealthy men have joined in booming the plans.

NO WILBRAHAM CLIMB THIS SUMMER.

SPRINGFIELD, MASS., April 5.—The Automobile Club of Springfield has decided not to hold the Wilbraham mountain climb this year on account of the high expense incurred by the event. Last year it cost the members about $1,200, and it is the opinion here that the money could be spent better toward improving roads and in erecting signs. A committee has been appointed to inspect the road between Holyoke and Smith's Ferry and to report upon its condition, looking toward its reconstruction.

CAVALRY WILL GUARD LOOKOUT MOUNTAIN CLIMB

CHATTANOOGA, TENN., April 5.—So much interest has been taken in the hill climb which will be held by the Lookout Mountain Automobile Club, on Lookout Mountain, that it has been found necessary to make the affair of three days' duration instead of one, and perhaps the most important action in preparation for the event is the securing of Government troops to guard the course. Absolutely everything that can be thought of has been outlined and will be arranged.

The three days chosen are April 22, 23 and 24 and entry blanks have already been sent out to prominent manufacturers and dealers, there being eight races on the list, two free-for-alls, four for various classes of stock cars and two for motorcycles. Inasmuch as the hill is four and a half miles long and only a few cars will be allowed on it at a time and perhaps only one at a time, it will probably take some time to run off the eight events. It was this fact which influenced the club in setting three days for the festivities. While the troops have not been definitely secured, promises have been made to the club that the Government cavalry will be supplied, for there are a couple of thousand stationed at Fort Oglethorpe, Dodge, Ga.

Already work has commenced upon the course and a force of men is banking up the turns. The highway itself is a stone pike and needs little repairing. Owing to the frequent windings of the hill a system of block signal is being installed. The following is the list of events and prizes:

Event 1.—Free for all, no restriction as to weight, motive power or other construction. C. E. James Trophy.
Event 2.—Free for all stock cars. W. J. Oliver Trophy.
Event 3.—Stock cars listing at $4,000 and under. Hotel Patten Trophy.
Event 4.—Stock cars listing at $3,000 and under. Chamber of Commerce Trophy.
Event 5.—Stock cars listing at $2,000 and under. Manufacturer's Association Trophy.
Event 6.—Stock cars listing at $1,000 and under. Mountain City Club Trophy.
Event 7.—Motorcycle, up to 30 1-2-inch piston displacement. Chattanooga Automobile Club Trophy.
Event 8.—Motorcycle, up to 61-inch piston displacement. Lookout Mountain Automobile Club Trophy.

France Now Keen After Small Car Market

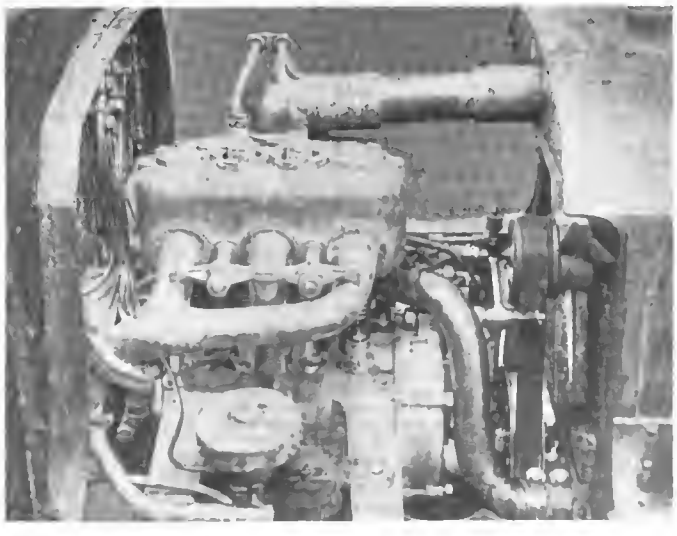
By W. F. Bradley

Panhard's Bid for the Small Car Business Shows Fine Proportions.

PARIS, April 1.—An epochal announcement has emanated from the big Panhard factory on Avenue d'Ivry, and the details of the new light car are now public. This is in the nature of a wide departure for the house of Panhard, in that it relates to the production of the first two-cylinder car brought out in the past ten years, the last one dating back to 1899. By many persons in a position to know, this is thought to be a bid for the small car market, now so much larger numerically than the big touring car business. This first impression is further strengthened by the announcement that this new chassis will be produced in very large numbers. An inspection of the lines of the chassis show that without alteration it will be available for taxicab use, which contingency was doubtlessly considered by the far-seeing engineers of the "Anciens Etablissements," and which swells the possible field greatly.

Whatever the intention, the fact remains that here is a little, light, low-powered car with Panhard materials and workmanship, built to sell at a low price. At least it is reasonable to assume that the price will be very close to its natural competitors of the same power, which would put it in the class of 6,000 francs or less. This would bring it into the United States at just under $1,800.

Inaugurates Many New Features for Panhard.—Despite the number of characteristic features, such as the shaft drive, live rear axle, Krebs carbureter, usual spring suspension, typical radiator, deep section pressed steel frame, long stroke motor and many other Panhard earmarks, there are also evident numerous new features of sterling worth. Thus, it has long been characteristic of this house to cast the cylinders individually and with valves on opposite sides. The new engine has these in pairs with integral water jacket, and valves placed side by side on the left. This allows the use of a single camshaft, simplifies the construction and cheapens it not a little.



Valve Side of the 8-horsepower Motor.

Following in their ordinary lines, the engine has a long stroke. The bore is 80 mm. (3.15 inches) by 120 mm. (4.72 inches) stroke, a ratio of 1 to 1.5. This size easily gives the rated 8 horsepower without unduly high piston speed; in fact, it would be the A. L. A. M. rating for this bore.

Thermo Siphon Cooling Adopted.—Another departure which also makes for simplicity is the abandonment of the pump. In thus approving the natural circulation of the water, the tendency of the times is concurred in by one of the most conservative firms in existence. The radiator is unchanged, but the water pipes are enlarged in size, bends are eliminated or made of a large radius, while their length is reduced to a minimum. The outlet is on top midway between the cylinders, and the water enters at the front side of the jacket at an angle.

A large diameter fan is placed between the engine and the radiator. This is cast as a unit, blades, hub and all. It is of aluminum and the blades are ribbed for strength on the under side. A wide belt drives from the pulley on the crankshaft so that the fan speed will be high. The fanshaft is hung on one end of a rocker, the other being spring retained in position. This arrangement is such that the spring automatically tightens the belt and keeps it tight.

Careful Yet Simple Piping Arrangement.—The exhaust valves are placed at the front and back of the motor. This brings the two inlets together in the center and allows a simplified inlet pipe without in any way complicating the exhaust header. The latter has been carefully studied out and is given a slight downward slope to the rear. The diameter is increased at the junction of the second part and the flange at the rear is set on a diagonal, which allows the pipe to be dropped as soon as the two bolts have been removed.

The inlet is very short and stubby, leading down to the Krebs carbureter, placed midway between the feet of the crank case. The pipe for the hot air supply is readily seen on the valve side.

Single ignition is fitted with a magneto as the source of current. The latter is placed crosswise of the motor in front of the forward foot of the case, and rather low down. But two plugs are provided, placed over the inlet valves. This makes the ignition system one of marked simplicity.

Lubrication Shows Simplicity, Too.—The lubrication has been worked out as carefully as any other feature, and while presenting few new ideas, is noticeable for its simplicity. An oil reservoir is placed between the crank case feet on the right side and has a capacity of sufficient oil to take the car 150 miles. The oil is forced by pressure to an indicator on the dash from which it flows to the various bearings and thence into the bottom of the case. Interior lubrication is by splash.

The engine is attached directly to the main frame, but the transmission is carried on a pair of cross members. The former is a departure from ordinary practice. The frame itself is of pressed steel of a very deep section and is narrowed in two directions. In front, the side members are brought close together to dispense with the usual engine sub-frame and also to allow of a big steering lock. At the rear this narrowing takes the form of an uplift or drop, as you chose to call it, which lowers the center of gravity, with plenty of clearance over the axle.

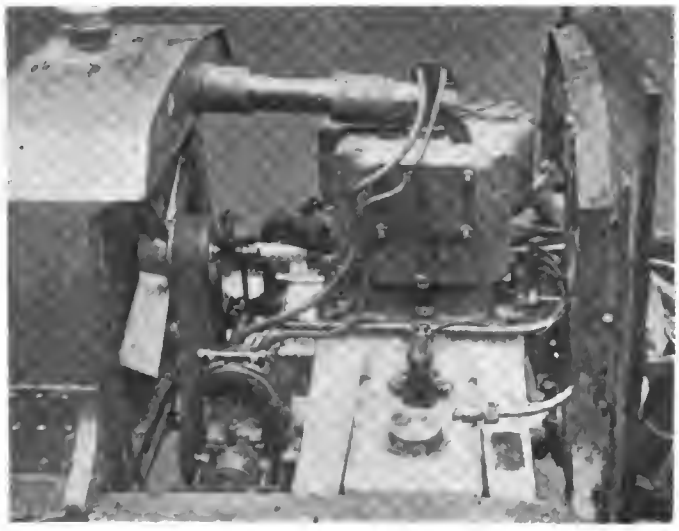
The spring suspension shows the same as other Panhard models of late years, viz., flat semi-elliptic springs in front, shackled at the rear end only, and three-quarter scroll elliptic at the rear attached directly to the frame at both ends. The forward end is attached through the medium of a dust proof joint which allows of slight rotation.

Radical Change in the Clutch.—From the engine, the drive is through the medium of a clutch, which shows a wide departure from past practice. Formerly the clutch used was of the multiple disc type and was carried in an extension of the gear-case. On this car the clutch is of the inverted cone type, leather lined. This is readily removable for the purpose of renewing the leather or adjusting the tension of the spring, the latter being placed between the flywheel and the cone. Thus it is hidden from view, but this procedure has the virtue of also keeping out all dust and dirt.

The gear box provides three speeds and reverse, operating on the selective principle. The gears are of large diameter, with wide face and coarse module pitch. They are operated by the usual hand lever, which is the inner one of the two.

The control is by means of foot accelerator and throttle lever only, the spark advance being fixed. There are two pedals, the right one being connected to the brake on the driving shaft back of the transmission. The other is the usual clutch pedal.

Between the clutch and the transmission is a split shaft coupling with a square hole, a squared shaft working within this, and thus allowing the ready removal of either the clutch or transmission without disturbing the other.



How the Magneto Is Placed on the Motor.

The transmission shafts all run on ball bearings, but the engine bearings are plain. The balls are liberally used throughout the car on wheels and other parts.

Between the transmission and the rear axle carrying the differential case, the cardan shaft has two universal joints, one at each end. The differential case shows a bold stroke in the utilization of aluminum, this being a place where steel is ordinarily used. This is riveted to the steel tubes which carry the weight of the car and to which the springs are attached.

Ball Bearing Wheels Are Carried by Tubes.—The rear wheels, which are upon ball bearings, are carried by the tube within which the shaft proper does the driving by means of clutches at the outer ends. These allow some freedom of motion and in this way the axle neither carries any weight nor receives any of the destructive road shocks.

A BRIEF HISTORY OF THE HOUSE OF RENAULT

PARIS, April 1.—The union of the Renault Frères has been broken by the death of Fernand Renault, eldest of the three brothers who at one time formed the world-famed firm of automobile constructors. An attack of cancer, aggravated by the decomposition of the blood, brought about the end of Fernand Renault at the age of 44 and at a moment when he was about to enjoy the fruits of his rapidly earned fortune.

Fernand Renault was only introduced to the automobile industry through his brother Louis, who now remains at the head of the huge factory on the banks of the River Seine. The three brothers, Fernand, Marcel and Louis, were all destined by their father to succeed him in a wholesale linen drapery establishment on the Place des Victoires, Paris. Louis rebelled at the idea of passing his life behind a counter, and at 19 years of age quit his father's establishment to enter the Delaunay-Belleville firm as a draughtsman. At that time the automobile hardly existed, even in France, and was altogether unknown at the Delaunay-Belleville shops. Being interested in the budding method of road locomotion, Louis Renault applied to Panhard-Levassor for a position as a draughtsman, and was bluntly refused by Levassor with the remark that "No amateurs were wanted."

The amateur returned home, appealed to his mother for a small workshop adjoining the family dwelling at Billancourt and began the construction of automobiles. His first machine embodied the principle of direct drive by cardan shaft and revealed to the world that a master mind had tackled the problem of the automobile. Success in speed contests came as early as 1899, when the little vehicles, driven by 2 3-4-horse-power De Dion motors, won practically all the events of the year.

Marcel Renault soon threw down the tape measure and ran to assist his brother in the new industry. It was not an important industry at that time, for when the firm was constituted in 1898 the number of workmen employed was six, the factory area about 350 square yards, and the annual production six small cars. Louis Renault was responsible for the engineering branch of the industry, while his brother Marcel took charge of the commercial end and drove the small cars in all races. This continued until 1903, when in the ill-fated Paris-Madrid race Marcel Renault met his death, and his elder brother Fernand took full control of the commercial end of the factory.

A 10 years' contract of partnership between Fernand and Louis Renault expired last December. The elder brother, feeling that his health was not satisfactory, decided not to renew the agreement, but for the rest of his life to enjoy the fruits of his toil. At 43 years of age he was wealthy, decorated with the Legion of Honor and apparently destined to a long life. At the end of last year, therefore, he quit the factory, which had grown from an area of 350 square yards to nearly 60,000 square yards, from an output of 6 cars to 5,000 per annum, and from a staff of 6 to an army of 2,600 workmen regularly employed.

At 32 years of age "Monsieur Louis," as he is familiarly called at the factory, remained at the head of the works he had created alone 11 years before. A few months later and death ratified the dissolution of the partnership by the remvoal of the elder brother Fernand. Now Renault Frères has become Louis Renault, and one of the world's most important automobile factories is controlled by a young man whose success has been phenomenal, but to whom fate has been cruel.

Britain Intently Studies Aerial Flight Progress

By Joseph A. Mackle

LONDON, April 1.—The exhibition of flying machines and their accessories, organized by the Society of Motor Manufacturers and Traders, and which opened its doors at Olympia on March 19, has already proved a gratifying success. Right from the first there has been evident a keen interest on the part of the public, while representatives of the military and naval authorities, together with many of the foreign atttachés, have been devoting considerable time to a detailed study of the exhibits. This afternoon the Prince of Wales paid an extended visit and, altogether, these marks of distinguished favor and interest cannot but have a stimulating effect on the progress of aviation in this country.

As an exhibition the present collection is generally admitted to be quite as imposing as the earlier Paris Salon, for while the number of machines is somewhat less, the French show suffered from the scattered nature of its exhibits, due to the commercial vehicles.

Wright Among Absentees.

The collection of full-sized machines numbers 11, compared with 16 at Paris. The absentees comprise the Bleriot and Antoinette monoplanes, the Clement dirigible, several of lesser importance, but also—and its non-appearance is the cause of much disappointment—the Wright flyer. Fortunately there is a large scale model of this machine included in the excellent and extensive collection of models which occupies several stands in the center of the building. This section was specially organized by the Aero Club, under whose auspices also the show is being held, and it serves well to demonstrate to the public the construction and differences of the various machines in a much clearer way than is possible with the full-sized and more cumbrous flyers.

The engine and accessory sections are likewise fully representative. The special lightweight motors of the French makers, such as the R. E. P. and the Guome, are staged along with the more substantial Belgian productions of E. N. V., Vivinus and Metallurgique. There are also many creditable productions of British firms who have for the most part favored reliability and endurance rather than extreme lightness of weight.

To deal with the full-sized machines first of all, the center of attraction, doubtless on account of its size and central position, is the Wellman airship, designed for the Wellman Arctic expedition by Melvin Vanniman, who is busily in attendance. To-day's report of the almost complete success of Lieutenant Shackelton's expedition to the South Pole, doubtless greatly assisted by his motor-propelled sledges, has caused even greater interest than before to be shown in this Wellman dirigible, with which an attempt will be made to reach the North Pole late this year.

Voisin Biplane Shown in Several Examples.

Three examples of the Voisin biplane are shown. F. R. Simms, as sole concessionaire, exhibits the standard Voisin machine, which has undergone no change in design. The engine, however, is the production of the Simms Works and is of the V type with six cylinders rated at 50 horsepower. The second example is the actual machine with which Moore Bra-

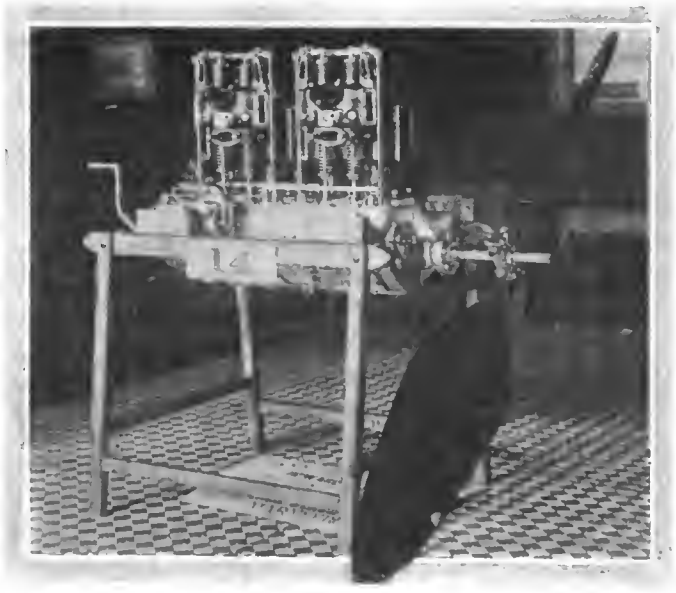
Taxicabs Outside the Aero Show, at Olympia, London. Note Spare Wheel Carried.

bazon has flown at Issy with such success. In this the distance between the main planes has been increased to 2 meters from the 1.5 meters, which is the figure for the standard machines. "The Bird of Passage," as it is styled, is equipped with an eight-cylinder E. N. V. engine of 65 horsepower, driving a twin-bladed propellor direct at 1,000 revolutions per minute. After the close of the exhibition this machine will be flown in this country at a place of favorable location.

The third Voisin is also a modification of the standard machine and is now known as the Delagrange biplane. The usual four vertical planes joining the main surfaces are absent in this machine and as they were dispensed with by Delagrange himself after his original flights, it is to be presumed that no loss of stability results. The engine is an eight-cylinder Antoinette of 55 horsepower and of the regular Antoinette design.

The "Short" Wright Machine Is Tailless.

The first of the British machines is shown by Short Brothers, the well-known balloon manufacturers, who are also building the Wilbur Wright biplanes (named thus in full to distinguish from the British Howard Wright machines) for the British concessionaires, Jarrott and Letts. The Short machine is not completed, but sufficient of it is on view to indicate the apparent soundness of its principles—a tribute which cannot be paid to several of the full-sized machines and many of the models elsewhere in the exhibition. It is a biplane, but of the "tailless" rather than of the Voisin type. The machine has also no outstanding rudder, steering being effected by means of four interconnected rudders, arranged in pairs just behind the extremities of the main planes. Where these rudders are situated the main planes are broadened out fore and aft and the lips thus formed can be flexed in opposite directions to control the lateral stability. Propulsion will be effected by an eight-cylinder V type British engine of 60 horsepower driving two rear propellors by chains. The machine is constructed of wood throughout and is a flexible rather than a rigid structure. The trials of this machine, to be held in a few weeks, are looked forward to with more than usual interest.



Four-Cylinder, 50-HP. Metallurgique Aero Engine.

The Howard Wright machine, on the other hand, is constructed of steel tubing throughout, the main members having a circular section, while the vertical struts are pear-shaped, to lessen wind resistance. All joints are rigid and have been welded by the oxy-acetylene process. The Voisin machine has been followed in its main lines, but the front elevator is of the biplane type and the main planes have small flexible silerons at the extreme rear corners. Interesting is the arrangement of the chassis on four wheels, diamond fashion, the idea being that the aviator may first drive over the ground until he has become accustomed to the machine. Motive power is supplied by a 50-horsepower four-cylinder Metallurgique engine driving a novel arrangement of a pair of two-bladed propellors in tandem

The Prince of Wales at the Olympic Aero Show, Examining Capt. Windham's Biplane.

at the rear. These two propellers are connected by a differential gear and revolve in opposite directions at one-third of the engine speed. The front propeller is somewhat larger in diameter than that at the rear. It will be interesting to note results.

Bregnet Biplane Has Been Changed Since the Salon.

The Bregnet biplane is quite distinct from the machine of this name exhibited at Paris, which was a combination of helicopter and biplane. The present biplane machine is unusual in having no surface forward of the main planes which are themselves mounted so that they can be tilted for elevating and righting purposes. A set of large planes comes in the rear, three above and one below, with two vertical rudders between. The structure is built up of large steel tubes and the members are so jointed that the machine can be easily folded up for transport. Continental fabric is used for the plane surfaces and a novel feature is the strengthening of all the forward or cutting edges with sheet aluminium. The engine is a 75-horsepower Gobron Brillie with the four cylinders arranged X fashion, driving a tractor screw in front—another novel feature for a biplane.

Captain Windham, the founder of the new British Aeroplane Club, shows a biplane machine of his own design built by Pischoff, of Paris. Between the two main planes are small righting planes operated by a movement of the operator's body. A rigid wooden framework connects the main planes with the rear elevating planes, which are almost as large as the main surfaces. The elevators and rudder are controlled by a double movement of a single lever, as in the Wilbur Wright machine. A four-cylinder Dutheil-Chalmers engine is fitted and this drives a single rear screw.

Monoplanes are represented by the R. E. P. and the Weiss, the more successful Bleriot and Antoinette machines being absent. The R. E. P. has been made in England and differs in no way from the one shown in Paris. The Weiss is a more novel production, and, like the Avions of Ader, closely follows bird form. The long monoplane surface has a cane and bamboo framework. No tail is fitted, but two small planes are let into the rear edges of the main wings. These planes are operated by pedals and are so controlled that they may be used together, to rise and fall and in opposition, for steering and righting. Two rear propellers are chain driven by an eight-cylinder engine.

De La Hault Ornithopter Is a Curiosity.

Two very curious machines complete the list. The De La Hault ornithopter consists of a light upright framework with a pair of fabric-covered blades or paddles connected through a system of gearing to the engine, which is at the bottom of the frame with its crankshaft vertical. The gearing causes the paddles to give an alternate downward beat followed by a feathering motion on the upward stroke. The machine is said to have raised itself vertically from the ground, but a separate means of propulsion would be required for horizontal motion.

Finally the Lamplough machine is quite novel. The main sustaining planes are of the biplane type and in addition there are four longitudinal central planes arranged in pairs. These planes have a rocking movement imparted to them by a link motion. In addition to this rocking motion about the hinges on top of the supporting columns the columns themselves undergo a separate rocking motion so that the planes trace out a figure of eight each cycle with a feathering motion on each up stroke. Apart from this lifting device and the main sustaining biplanes, there are the rear elevating planes and rudders. A separate motor will operate two propelling screws in the rear. These, however, have not yet been fitted. The idea embodied in this machine is entirely novel and its development merits attention.

The present show was undertaken as an educative step and hence the absence of much business will not cause disappointment. Late reports indicate many good inquiries and a moderate amount of sales have been booked by the accessory and engine-makers and to a limited degree by the exhibitors of the Voisin types of machine. It is interesting to note that almost every exhibitor offers to guarantee a set performance for his machine. Usually this is limited to a two-mile flight, but even this much proves the makers' belief in their flyers.

WRIGHT COMPLETES CONTRACT AND PUPILS FLY

PARIS, April 1.—Wilbur Wright has completed his contract with the Lazare Weiller committee by the formation of three pupils capable of handling the American aeroplane alone. This week the pilot left Pau and returned to Paris, giving his pupils before leaving the right to beat any of his records. They were satisfied to commence by winning the Aero Club of France prizes for a flight of not less than 250 meters. Paul Tissandier first mounted the machine and in a few minutes had won the beginners' prize. Pleased with this, he was off again a few minutes later and when he settled down again had made 10 rounds of the course, or a total distance of 18 1-2 miles, in the official time of 27 minutes 59 seconds. Comte de Lambert followed on the same machine, won the 250 meters prize, then also accomplished 10 rounds; time, 27 minutes 11 seconds.

The success of the pupils shows how ill-founded are the reports that the Wright aeroplane can only be handled by professional acrobats after a long training. Of the three pupils only Paul Tissandier is a skilled sportsman, and not one of the trio is such an apt pupil as a score of automobile race drivers who might have been selected. Yet with men of ordinary ability it has been possible in a little more than a month, and by lessons of only a few minutes' duration, to form three aeronauts capable of handling the machine under all normal conditions. As the three pupils are now about to become teachers in their turn, it is certain that Wright machines will play an important part in European aeroplane races this year.

One of the Wright aeroplanes used at Pau has been shipped direct for Rome together with an engine, spare propellers and all accessories. Wilbur Wright has returned direct to Paris, while his brother and sister have stopped at Le Mans on their way to the capital in order to visit the ground rendered famous by last year's flights. The two brothers and their sister will be in Rome early in the month of April, when Wilbur will make demonstrations before the Italian authorities for a fortnight. After this it is believed that a return will be made to America to complete the army contract interrupted by the accident to Orville Wright.

Just before leaving Pau the King of England paid a visit to the American aeronaut's camp and was given an opportunity of watching the machine at work. Orville Wright undertook to explain the mechanism of the aeroplane and King Edward did not fail to congratulate the brothers on their skill as flyers.

Clement Will Build a Much Greater Airship.

PARIS, April 1.—Adolphe Clement, pioneer automobile manufacturer, having sold his aerial yacht the *Bayard-Clement* to the Russian Government, has given orders for the construction of another one, larger and more powerful than the first. The new Bayard-Clement dirigible balloon will have a capacity of 212,000 cubic feet, compared with 123,000 cubic feet of the present airship. Its length and diameter have not been definitely decided upon, but an idea of its dimensions can be gathered from the fact that an airship garage is about to be built 330 feet in length and 88 feet in height—equal to an eight-story tenement. The balloon will be equipped with two independent engines, each one capable of driving the vessel under normal conditions, and the two together making possible a high rate of speed. With this new dirigible, the largest in the world with the exception of the Zeppelin, it is declared that voyages from Paris to London or Paris to Brussels and return will be quite possible.

AUTOMOBILE GASOLINE INVOLVES COMPLEX PROBLEMS

By Thos. J. Fay

GASOLINE, as the name of the liquid fuel used in automobiles, is a misnomer, in view of the practice in which all the fractions of the distillate, between 125 and 200 degrees Fahrenheit, are used in the mixture, whereas gasoline proper is a closely limited distillate, which comes off between 140 and 158 degrees Fahrenheit. Gasoline, as it is used in internal combustion motors, as they apply to automobile work, holds enough of the more volatile fractions to assure that the motor can be started cold, and if the means for heating are adequate the whole content of the fuel is burned in the process to more or less completeness, with a certain amount of carbon deposited in the combustion chamber, as evidence of any incomplete combustion.

The right name of this liquid fuel, in view of the number of fractions included, is "automobile gasoline," or automobile fuel, and that the fuel will take on many phases in the course of time is proven by the wide range of mixtures thus far used, with fair success, despite the trouble experienced in many attempts to use kerosene oil. True, kerosene oil has been and is used to-day, and the process is attended with good success in the field of its activities. Confining the discussion, however, to automobile work, it is certain that the day has passed when kerosene oil holds forth any further attractions, and what now presents itself is more by way of an adjustment of the details to suit the conditions as they really are.

When, in the early days of the automobile, gasoline (in fact) was used, the average autoist provided himself with a hydrometer, and when the gasoline failed to come up to a fitting standard it was easy enough to put some of the suspected liquid in a test tube, as shown in Fig. 1, and if the test indicated that the specific gravity of the liquid was in the neighborhood of 0.67, the conclusion reached was affirmative. The test was quite accurate, in the main, although it must be remembered that the hydrometer would not distinguish as between gasoline and some other liquid of the same density.

Fig. 1.—Hydrometer in single liquid.

That the test would not disclose the presence of water should have been well understood, since, as Fig. 3 shows, the water would settle to the bottom, and the hydrometer could not very well be at two levels at one time. True, the illustration is a little exaggerated, in that more water is indicated than the amount that would be sold for gasoline even by a merchant of "accentuated oil acumen." Incidentally, this same illustration will help in the process of reaching the conclusion why the hydrometer measurement is of no avail at the present time.

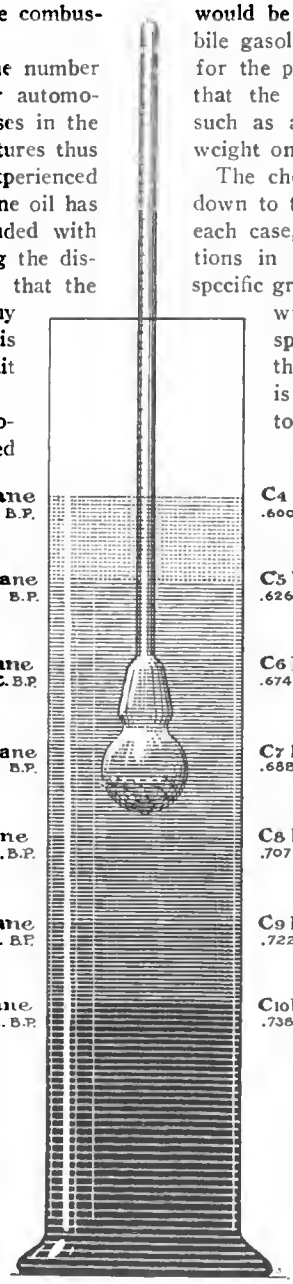


Fig. 2.—Test is valueless if there is a plurality of liquids.

Automobile Gasoline Is a Composite Product.—If it is admitted that oil and water cannot be tested by means of a hydrometer, in the manner as shown in Fig. 3, with a view to determining the specific gravity of the whole, a mere glance at Fig. 2 will be enough to "let the cat out of the bag" when it comes to the testing of present-day automobile gasoline, with a view to determining as to its composition, through the readings from a hydrometer. If water and gasoline cannot be tested, as in Fig. 3, in which there are but two liquids, what a small chance there would be of testing the complex liquid fuel called automobile gasoline in a test tube, using a hydrometer of any sort for the purpose! Referring to Fig. 2, it will be to observe that the several fractional distillates of hydrocarbon oils, such as are almost invariably found in gasoline, differ in weight on the one hand and in volatility on the other.

The chemical formulæ of the respective fractions are set down to the right of the test tube, under which formulæ, in each case, will be found the density of the respective fractions in specific gravity, as, for illustration, $C_4 H_{10}$ has a specific gravity (S. G.) of 0.600. On the left side of the tube will be found the customary name given to the respective fractions, and under the name of each of them the boiling point (B. P.) in degrees centigrade is also set down, as, for illustration, Butane (at the top of the list) boils at one degree centigrade.

By no stretch of the imagination can one reach the conclusion that a hydrometer will be of the slightest value in any attempt to determine the composition of a mixture of this character, nor would agitating the mixture help out, so that the license here taken, resulting in a display of the several fractions of the crude oil as lamanæ, is in no way to the detriment of accuracy, in this attempt to illustrate the point to be made.

The List of Contents Is Far from Complete.—Besides the seven fractions listed alongside of the test tube, Fig. 2, there is a long list of hydrocarbon compounds that can be and are used in automobile gasoline, to an extent not easy to predict. Some of the remaining fractions, not all of the same school, are as follows:

Hexahydrobenzine ..$C_6 H_{12}$,
S. G. 0.760, B. P. 69 deg. C.
Hexahydrotoulene...$C_7 H_{12}$,
S. G. 0.772, B. P. 97 deg. C.
Benzine .....$C_6 H_6$,
S G. 0.884, B. P. 80.4 deg. C.
Toulene.....$C_7 H_8$,
S. G. 0.871, B. P. 111 deg. C.

NOTE. — S. G. = specific gravity, and B. P. = boiling.

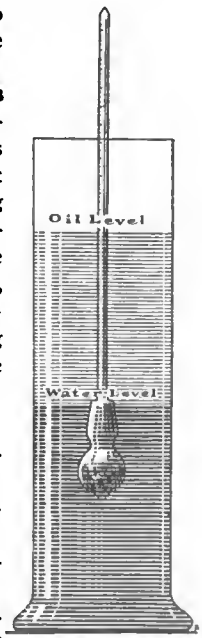

Fig. 3—Indicating futility of test.

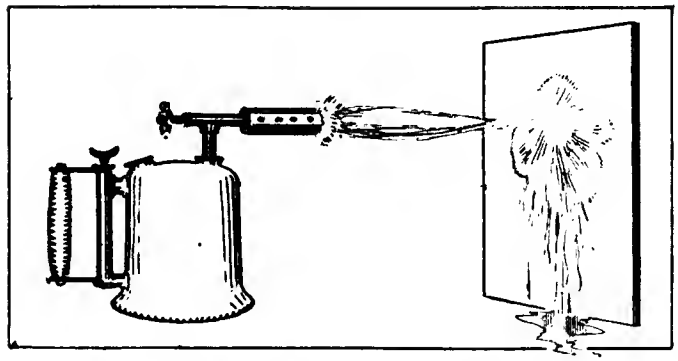

Fig. 4.—Heavy distillates will not burn and will pass over.

No mention has been made of alcohol, of which there are two classes, i. e., (a) methyl (wood spirits), and (b) ethyl (grain) alcohol. Of the alcohol products, it is assured that the only reason why they are not mixed up in automobile gasoline is because the market for alcohol is such as to render the same higher in price than the price which the other contents command at the present time, with small chance of any immediate improvement, considering present commercial conditions.

Let it not be supposed that the distillates, as mentioned, represent even a fair share of all the possible products of the paraffine, or other series, from which volatile hydrocarbon liquids are derived. Nor is it the purpose, at this time, to go into the question, at any further length than to point out the small chance any motorist would have in any attempt to determine as to the quality of the liquid fuel, such as might be purchased for his automobile, putting dependence upon a hydrometer, or, for that matter, any crude means, ready to hand. Of the distillates set down alongside of the test tube, Fig. 2, all are of the paraffine series excepting octane (which is from the methane series), and all are found in gasoline, as a rule, referring, of course, to the product to be had for automobiles.

Some Peculiarities of Automobile Gasoline.—If the several distillates that go to compose a given liquid have not the same boiling point, it requires no stretch of the imagination to see wherein trouble can arise if the conditions are not suited to the difficulties. Fig. 4 is of a simple gasoline torch, such as should be in the repair kit of every autoist, and if this same torch is filled with gasoline out of the tank of the automobile it will enable the autoist to see for himself that the mixture is not with a common boiling point for all the contents, for, if the torch is lighted, and if the flame is directed at a plate (a sheet of steel serves well), some of the gasoline will burn, and the balance will pass through the flame and impinge on the surface of the plate, resulting in a pool of the heavier portions of the fuel, on the ground, under the plate.

What does this show? First, that all the fuel is not of the same volatility, and again that the part that has the highest boiling point must be allowed the most time in which to burn. But if the available interval is the same, as it must be, for all the fractions in the automobile gasoline, there is plenty of room for speculation, and there is need for one of two things, i. e., (a) either the fuel must be adapted to the work to be done, or (b) the means for the use of the fuel must take into account the complex nature of the same, and the difficulties involved.

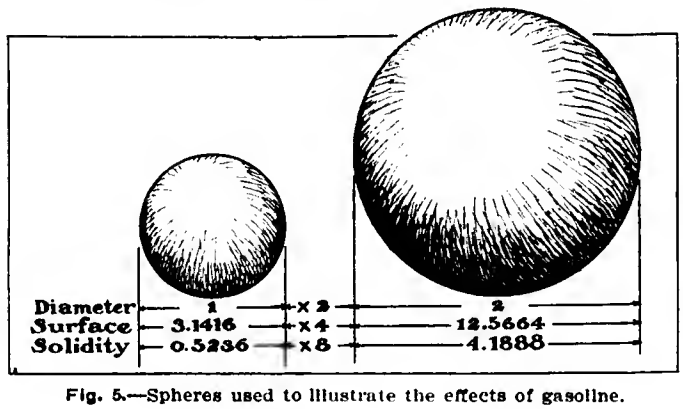

Fig. 5.—Spheres used to illustrate the effects of gasoline.

Gasoline Streams from the Nozzle of Carbureters.—When the piston in the cylinder of a motor displaces atmosphere, due to the travel of the piston, a partial vacuum is formed in the intake manifold, and because of the difference in pressure between the outside atmosphere and the partial vacuum in the "depression chamber" of the carbureter, gasoline is sucked out of the floatbowl, through the nozzle, into the depression chamber, in a stream, just as water is projected from a nozzle of a fire hose, and in the case of the gasoline, after it lands in the depression chamber of the carbureter, it is picked up by the current of in-rushing air and carried away, in globule formation, in route to the cylinders of the motor.

When these globules are very fine, and the air is well saturated with them, the product is not unlike a "fog," and if all the globules are of the same size, provided they are of microscopic dimensions, the resultant mixture will be good for the purpose, since it will vaporize and then burn, as a sequence, hence the motor will deliver power on a basis indicating that it is a homogeneous gas that is entering the cylinders. Unfortunately, the globules cannot be all of the same size unless all of the liquid is of the same character, so that it will be well to take a look at this phase of the subject and ascertain what will be the normal expectation under such conditions. Fig. 5 represents two spheres alongside of each other, so placed in order to point out the physical properties of spheres of different diameters, it being true that globules of gasoline are as spheres, and for the purpose in hand it matters not at all if the globules are very small, since we are dealing with relative sizes only, in actual practice.

If the two spheres are of one and two diameters, respectively, the surface of the large one will have four times the surface area of the small one, but, unfortunately (in this case), the solidity of the large sphere will be eight times the solidity of the small one. How, in the name of common sense, can eight times a given mass of gasoline vaporize in a given time if the surface is only four times as much? The exchange of heat is necessary in order to vaporize any liquid; to this rule gasoline is no exception, and since heat transfers, (a) in proportion to the surface, and (b) as the difference in temperature. It will require double the time to vaporize globules of double size, when, as a matter of fact, the time allowed is the same for all globule formations in practice, with the result that the larger, and the less volatile globules, enter the cylinders before they vaporize.

Gasoline Is Coked in the Cylinders.—Having traced the liquid gasoline into the cylinders, in which form we know it cannot be made to burn without first being vaporized, the next question is, what is the disadvantage? If wood is put on a stove, and if the drafts are opened sufficiently, the wood will be burned, and the remaining residuum will be ashes. If the wood is put into a sealed chamber *D*, as shown in Fig. 5, and provided a fire is maintained in the grate *E*, if the chamber *D* is sealed, so that air cannot enter through the door *C*, the wood so placed will be reduced to charcoal. If coal is put in the same chamber instead of wood, the product of the destructive distillation (for such it is) will be coke. In this case the fuel burned in the grate *E* is fired through the door *A*, and the ashes will collect in the pit *F*, while the gaseous products will go up the flue *G*. In this same process then we see that fuel is burned if it is allowed to assemble in the presence of its quota of oxygen, which it takes from the air, while it is "coked" if the air (in which oxygen abounds) is choked off.

Since gasoline is composed of carbon and hydrogen, if it is heated sufficiently, under suitable conditions, it too will form coke out of the carbon, and the hydrogen will be driven off. Fig. 7 shows a cylinder of a motor, in which it will be seen that coke *C* has collected in the combustion chamber, above the piston *B*, inside of the walls *A*. Since we know that a carbon crust does form in motor cylinders, it is not necessary to argue

as to the facts, but it is desired to find the reasons for the formation, in order that a remedy can be applied. It takes a little time to reach the conclusion that the process is precisely that which the old charcoal burner has used, for ages back, but, having evolved the idea, it will take more time to get rid of it, unless a means can be found by which liquid gasoline, of the complex mixture now in vogue, can be vaporized before it enters the cylinders.

It might be said that the gasoline burned in the cylinder of a motor is in the presence of atmospheric air, and on this account it should not be reduced to coke. But it is reduced, as is too well known to require further proof, and the reason why the air that enters the cylinder does not prevent the formation of this same coke is due to the mixture of the air with so much readily inflammable vapor of gasoline that the globules of less volatile liquid are not in shape to rob the fine vapor of its oxygen, even though there may be an excess of oxygen present. Further study of the spheres, as shown in Fig. 5, will aid in the process of reasoning, especially if account be taken of the short time allowed the gasoline to do its work.

Comparison of Carbon Deposit to Coke Not Far-fetched.—An examination in detail of the two products of combustion shows that the comparison is not a far-fetched one. The coal is purposely deprived of air in order that coke may result. The gasoline, deprived of its air, either purposely or otherwise, cannot help but produce the despised carbon residue. Not only are the processes by which they are formed very similar, but the physical and chemical forms of the two are very much alike. Coke is hard, brittle, porous and has a metallic luster. Carbon cylinder deposits are hard, brittle, porous but less so than coke, and have a metallic luster. The former is insoluble in any known liquid; so, too, is the carbon, which lack of air leaves on top of the piston. To dispose of an accumulation of coke it is crushed, being brittle, and washed or swept away. Similarly, to get rid of carbon, it is broken up and then blown out of the cylinder, or it may be combined with oxygen from decarbonizers.

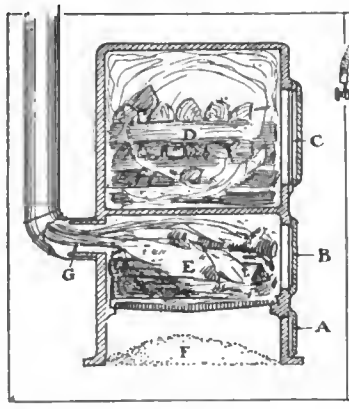

Fig. 6.—Coke is formed out of carbonaceous matter by heat in absence of oxygen.

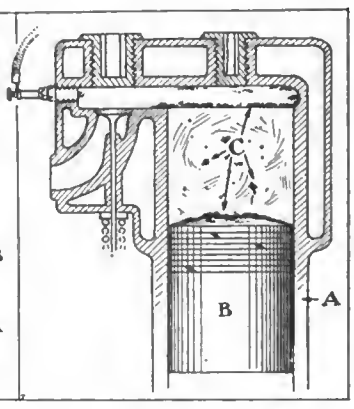

Fig. 7.—Carbon collects in the cylinders in the same way that coke is formed.

LAWS HAMPER TAXICAB USE IN MONTREAL.

MONTREAL, April 5.—This city would like to have taxicabs, and there are two concerns which would be glad to please the residents, but the laws of the Quebec Legislature are such that the taxicabs cannot get licenses to do a hacking business. The Legislature has ruled that all automobiles and motor vehicles come under its jurisdiction and that municipalities must not pass laws affecting them. Therefore this city cannot pass a statute which would allow of giving licenses to automobiles. If the law is amended, then the city would be able to take the necessary action.

NEW YORK TAXICAB COMPANIES MERGE.

NEW YORK CITY, April 5.—The president of the New York Taxi-Service Company has announced the absorption of the Hexter Taxicab Company. This will swell the number of vehicles operated by the new concern by 50, now in operation, 50 more ordered and 12 touring cars. This added to the previous figures will give Mr. Whipple's company about one-fourth of the total number of cabs operating in the city. One outcome of the combination, according to the officials, is the possibility of still more absorption with ultimate reduction of rates.

SOMETHING DOING IN ATLANTA, TOO.

ATLANTA, GA., April 5.—The announcement was made a few days ago that a second taxicab service would be started in this city. No sooner was this made public than Manager Dunn, of the first cab line, known as the Atlanta Taxicab Company, left for the North to buy more cars. The first vehicles obtained were low priced, but the second installment will be of a very high class. This company has a large force of men at work on its garage on Ellis street, which will soon be ready. This is a very favorable location near the center of the city.

DRIVERS WILL GET STRAIGHT SALARY NOW.

BOSTON, April 5.—A new plan, which is intended to put an end to many of the troubles in connection with the taxicab service here, has just been put into effect. This consists of paying the drivers a weekly salary in place of paying a percentage of the gross receipts and charging for the gasoline. This move of the Taxi-Service Company is expected to give customers better service.

NOVEL AUTOMOBILE REPAIR SHOP.

The most novel repair shop known to the automobile trade is that belonging to the J. F. Thompson Repair Company, of Oakland, Cal. It consists of a platform and enclosed body mounted upon a 40-horsepower Rambler chassis. Within this is located the repair shop, which is well equipped, having a lathe with 10-inch swing, two 12-inch emery wheels, key seater, polishing wheels, glass rack, tool cabinets, benches and complete plumbers' outfit. The power for the machinery is derived from a 3-horsepower motorcycle engine. The owners have selected as their motto, with which the exterior of the vehicle is decorated, "We repair anything from a stewpan to an airship."

This is typical of the firm, which is very progressive and nothing if not hustlers. The outfit itself bespeaks their progressiveness, being not an old cripple, but an up-to-date touring car chassis, while the body is very well built for the purpose and not an adapted dry-goods box. Under the circumstances the tool equipment is a remarkably complete one, including, as it does, many tools, such as a large diameter lathe, not ordinarily seen outside of a good-sized machine shop.

Despite the large number of tools carried and the big enclosed body the total weight is but 4,220 pounds. The owners travel about Oakland, San Francisco, and vicinity, plying their trade and making no attempt at specd.

How a Rambler Chassis Is Utilized for Repair Shop.

Automobile Cooling Systems Analyzed

BY MORRIS A. HALL

PART IV

CONSIDERING the relative value of detached and integral fins on radiator tubes, it might be said that the efficiency of fins is very nearly equal to that of other radiating surfaces when the fin thickness is restricted to that of the tube and the spacing suitably proportioned, but for any thickness the maximum ratio of the fin diameter to the external diameter of the tube is a fixed quantity, and, if exceeded, the loss is in proportion to the excess.

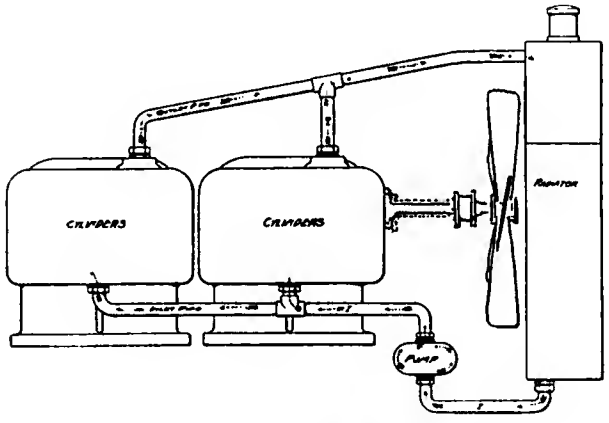

Fig. 14.—Diagram of typical cooling system.

In all of the above the surfaces and substances are treated from the viewpoint of inherent ability of stationary or fixed position. While the volume of heat to be dissipated is not great in the total, the time element enters, in that this dissipation must occur in a very short space of time. To cool a gasoline engine as used in the ordinary car with a cooler of the best possible materials, under the most favorable conditions and most efficiently, would require a radiator bigger than the car itself, if the radiator stood still or the air was allowed to flow through it naturally.

So to reduce the size to something that can be used, the relative efficiency is increased. This is done by an artificial flow of the cooling medium; in this case, air. This increase in the flow of air is brought about in two ways, usually working simultaneously. One of these is that the radiator does not stand still, but is moved with the car. This forces air through the cooler at a rate equal to the rate of speed of the car multiplied by the coefficient of loss. This would not be effective with the car standing still but the engine running, so a second artificial circulating means is provided in the fan.

Rapidly Rotating Fan Does the Business.—It is driven from the engine, and so rotates when that rotates. If the engine runs slowly and has little heat to dispose of, the fan runs slowly. When the former turns over at a maximum rate of speed, the fan, too, is making the highest possible number of turns.

Air is such a very bad conductor and metals are so good in comparison that in heating still air, the quantity of heat the air will carry off is practically the same with a number of metals. Even with the air artificially circulated, this remains true up to considerable speeds. For this reason, also, the thickness of the metal has little effect. The rate of transmission is inversely as the thickness, but so high compared to the air that the heat is supplied even through a thick plate faster than the air can carry it away. This is an added reason for supplying the latter at a very high rate of speed. Experimental data bears out this contention. Thus: heat flow in units per degree per square foot of surface per minute:

In still air	.0356
In gentle breeze	.0397
In fresh breeze	.0750
In fan blast	.0900

If any discussion of these results were necessary it would be sufficient to point out that under exactly similar conditions the fan blast removed nearly three times as many units of heat as were taken away at the slower air speed here called "in still air." In this connection it is to be regretted that definite figures corresponding to these rather indefinite phrases are not available, as it is believed that these would bring out even more forcibly the point made above. An Englishman, named Craddock, found that hot water in tubes, moved at the rate of 40 miles per hour, lost heat at 12 times the rate of tubes that were stationary. The inverse of his statement would be that fans and other provisions for circulating the cooling air at the rate of 40 miles per hour would be just 12 times as efficient as no provision whatever or natural air circulation.

This brings up the subject of fans, neglected by many as of little importance. Having just made out a case for the importance, a glance at some fans will be of interest. The fan problem may be attacked in either one of two ways, or perchance both. One of these is the location directly back of the radiator, drawing air through the radiator only. The other is the rear or flywheel location, drawing air through the radiator and thence across the whole of the engine, and thus effecting secondary cooling. Fig. 14 shows a diagram of a complete circulating system, in which the first method is utilized.

Great Variety in the Types of Fans Employed.—Even with this apparently simple and standard cooling arrangement, the appearance, type, and efficiency differ very markedly from one car to another. Thus at one of the recent automobile shows some one statistically inclined found that of 23 cars examined 7 had both forward and flywheel fans; 7 had rims around the outside of the fan; the number of blades varied from 4 to 8 (Fig. 15 shows one that has 12), the width of the blades varied from 3 to 6 inches, and the outside diameter ranged from 14 to 24 inches, the average being about 18 1-2 inches.

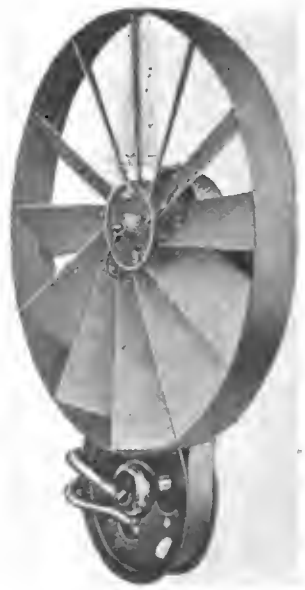

Fig. 15.—Example of the indiscriminate use of very many fan blades, a poor design.

With such a wide divergence in current practice there must be something wrong. This lies in the fact that the subject, instead of being handled with the care it deserved, has been shamefully treated. The fans were built, not designed, and when put to work either did the work or failed. In the latter case, a

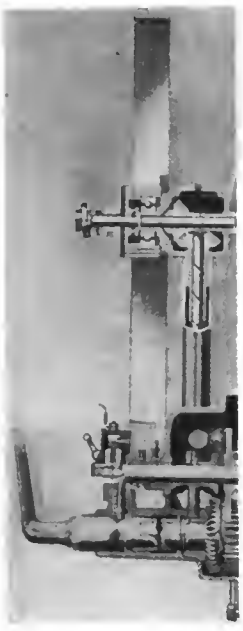

Fig. 17.—Bevel gear drive in section, showing clutch at left.

larger diameter was substituted, or the number of speeds increased, or the whole mechanism speeded up.

In the design of fans, the type enters; that is, whether of the disk or centrifugal style. Then there are the number of blades, width and angle of blades, external and internal diameters, speed of revolution, and a few minor points. For an enclosed fan blower of the centrifugal type the formula holds good:

Capacity, $C = 1.38\ r^2 D^3 N$, in which

N is the number of revolutions per minute.

D = the outside diameter in feet.

r = the ratio of inside to outside diameter.

This capacity is expressed in cubic feet per minute, under the condition that the full quantity can pass through the opening known as the blast area, without lowering the pressure in the housing. Under these conditions tests have produced quantities which only fell off from the formula rating by 10 per cent., and in some cases equaled it. From which it might be taken that it represents correctly the desired amount, under proper conditions.

However, this is for a fan with a housing, and unless the ordinary airtight bonnet may be considered as an imperfect housing, this formula will be of no service. By the time that constants have been determined and introduced to care for this, the result would be far from the above and, probably, equally far from right, if not actually incorrect.

Even this difficulty, made clear by the above discussion, does not excuse the lack of an experimental determination of the correct number and arrangement of parts.

Drive Shows Equal Diversity.—The method of driving the fan varies as much as does the type and features. There are the flat, round, trapezoidal, and other forms of belt drive, bevel gear, skew or helical gear and worm drive. In the case of all but the few strictly mechanical arrangements, there is expected to be some slippage, but in the latter case there can be none. So with the various gear drives, a clutch is provided which may slip at the time of starting, and thus preserve the fan from self-destruction, at that time.

The elements of a bevel-gear-driven outfit are shown in Fig. 17. The clutch is at the outer or forward end, and is there seen to be extremely simple, consisting only of a flat plate normally held in engagement by a coiled spring.

With the fan flywheel method of drawing air through, one of two ways is used: either the fan blades are made an integral portion of the interior of the wheel, acting as spokes thereof, or they are found distributed around the circumference, in which case they can be either integral or applied. In the first method, the disadvantage is that the clutch is either reduced to a minimum size by the length of the fan spokes, or, starting with the required diameter of clutch, the external size of the flywheel reaches to a figure which prevents its use. Between the two is the case in which neither one is as large as would be advisable, but the whole is such as to go in the car. Fig. 18 illustrates a flywheel of this type. This was used in connection with a disk clutch of very small diameter, but with a large number of plates. This type has the excellent quality of putting the flywheel weight where it should be and where it is intended to be. This can be stated in different language by saying that this form of flywheel has the greatest ratio of effective effort to actual weight.

The other style of flywheel fan has the blades external to the flywheel proper. This means that they may be applied or removed at will unless cast integral. One disadvantage of this form is the matter of available space. More clearance must be allowed around the fan than for a smoothly finished flywheel exterior. As this space is predetermined, it means cutting down the size of the effective part. This, in turn, means an increase in the dead weight to give the same flywheel effect. The latter is a permanent addition to the weight of the car. An additional disadvantage is that while the motor is running one must be careful of this rotating part, for with the external blades, it is dangerous and liable to take off a hand or a few fingers.

This is not so of the first mentioned arrangement. An advantage of the external fan blades is that their location is such as to give additional ability as a fan, in that the larger diameter will handle more air, and the same increased size give an increased lineal speed for the same number of revolutions. Summed up, this type gives the maximum fan and the minimum flywheel action. The first type, on the other hand, gives the maximum flywheel action with less weight and slightly decreased fan results. Fig. 19 is a picture of a typical example of the second kind, showing the fan blades cast integrally.

Oil Cooling Presents Some Good Features.—In one of the earlier chapters of this story mention was made of the use of other liquids than water for cooling purposes. In this category would come water with a very large percentage of foreign matter, such as alcohol, calcium solutions, glycerine, or other substances added in such quantities as to alter the boiling and freezing points and the general performance of the resulting liquid. These liquids would be different, but what were referred to were other liquids of an entirely different nature fundamentally, such as oil, or any petroleum product.

This has many times been advocated for cooling purposes, particularly in cold weather, when much stress was laid upon the very low freezing point of oil as compared with water. This means that every cold spell the owner of a water-cooled machine must introduce into the cooling system a solution which will combine with the water and reduce the freezing point of the whole below any temperature that is liable to be met. Otherwise, the chance is taken that the fluid will freeze, and in so doing burst the water jackets. This necessitates new cylinder casting, with consequent expense, work and delay.

With oil this source of trouble would be excluded, for even the thinnest, lightest oil has a freezing point below any temperature met in the temperate zone. So this factor may be eliminated and attention concentrated on the boiling point. It varies

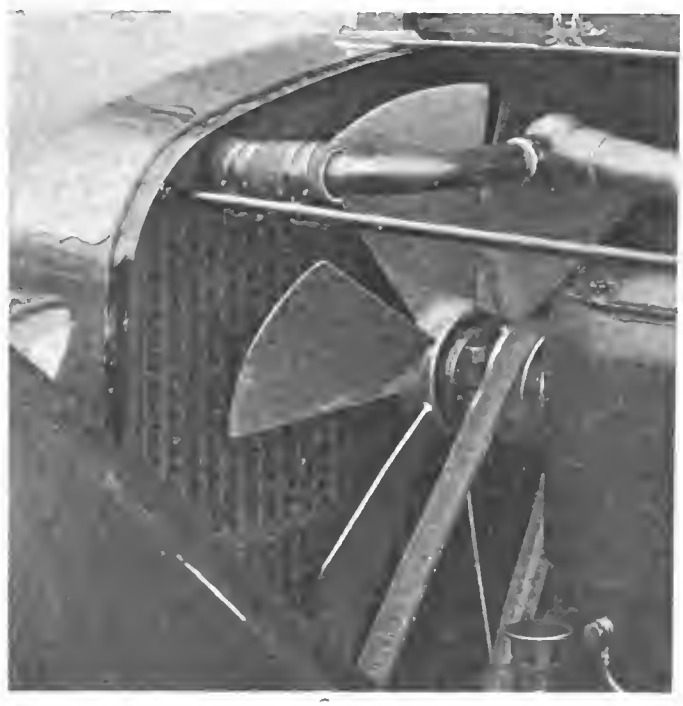

Fig. 16.—Shows a very good arrangement of fan and piping.

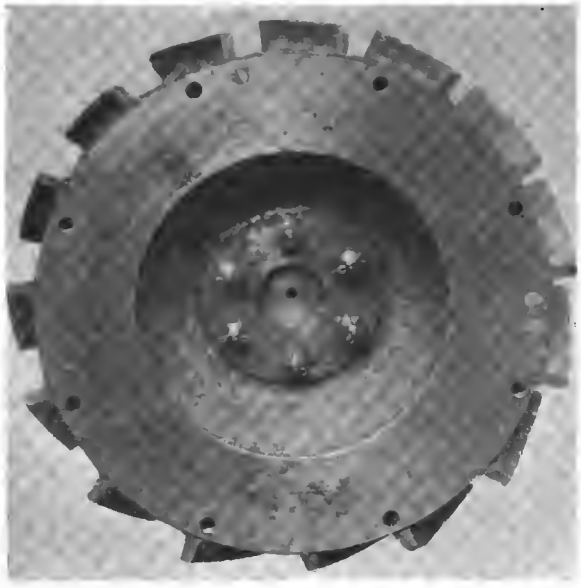

Fig. 19.—An alternate disposition of flywheel and fan.

with different substances, and in substances of the same general character varies with the chemical composition. In the distillation of petroleum the products have the same general composition, but the boiling point differs. Then a table of boiling points will look like this:

Ethyl Alcohol	173	degrees	Fahr.
Water	212	"	"
Saturated Brine	226	"	"
Light Lubricating Oil	383	"	"
American Mineral Oil	383	"	"
Dodecane (Paraffin Series)	385	"	"
Tridecane " "	421	"	"
Tetradecane " "	457	"	"
Triamylene (Olefine "	478	"	"
Pentadecane (Paraffin "	491	"	"
Linseed Oil	597	"	"

It should not be taken from this that these temperatures are advocated or even advisable. The point to be brought out here is that any substance whose boiling point is above that of water will be more useful. If the temperatures such as those at the end of the table were used the engine would be hopelessly ruined. Moreover, the use of vegetable oils is not recommended, although they are given in the table.

There are several firms in the Middle West using oil as a cooling medium, one of which has been using it for three or four years with the best of success. These people put their machines out into the hands of persons who have absolutely no mechanical skill and very little mental capacity. This being the case, there is a great necessity for a machine that is fool-proof. Oil as a cooling medium seems to fill the bill in this respect, for no amount of neglect can do the slightest harm. Cold weather will not affect it, at least not in any dangerous or destructive way, heat has no injurious results, care of the whole system is reduced to a minimum, a big point when the class of labor just mentioned is employed, in fact the only real necessity is the replenishing of the oil lost in natural and unavoidable ways, such as small leaks, slight evaporation losses due to inequality of the oil, and other minor ways. So it may be said, without fear of contradiction, that this cooling medium is ideal.

Radiators Are More Efficient with Oil.—Another claim made for oil used for this purpose has to deal with the fact that with water or other low-boiling-point fluid, the radiator is not worked to its full efficiency. It is said of honeycomb radiators, in particular, that they are too efficient; that is, they cool the water too much. This objection would be met squarely by the use of any liquid which had the power to remove a greater amount of heat from the engine, this being restricted in the case of water by its low boiling point. Oil would do this, anad coming to the radiator with a greater initial temperature, would require the same final temperature, thus calling for an increased efficiency on the part of the radiator.

Tests which have been made upon oil bear out this contention. Fig. 20 shows the arrangement of the apparatus used in the test. In the foreground is the engine, and beyond it and slightly above is seen the fan housing. At the right is the prony brake, and beyond it the starting rheostat for the electric motor which drove the fan. At the left are the pump and tanks to measure the weight of the oil, set upon scales. Some of the results obtained were:

RADIATOR NO. 1.

Fluid	Heat Dissipated Units	Temp. Drop Degrees.
Water	490	25
Oil	700	12

RADIATOR NO. 2.

Water	490	40
Oil	700	18

From these results the conclusion is drawn that all radiators are at least 50 per cent. more efficient with oil than with water. This, as stated above, allows of abstracting more heat from the motor, which in turn allows of working it at a much higher temperature, and thus a greater thermal efficiency.

An indirect advantage of oil-cooling is the decrease in the mechanical losses with increased temperature. This latter is a mooted question, but the majority of evidence seems to favor the statement that higher temperature means greater mechanical efficiency. The writer's own experience in this matter showed for the same load and speed, same general conditions throughout, an increase of from 10 to 15 per cent. in mechanical efficiency was possible by increasing the temperature of the outgoing water from about 160 degrees Fahr. up to boiling point, or as close thereto as could be maintained using water. One test, to prove this point, resulted as follows:

Water Outlet Temp.....	69	150	185	203	220
Horsepower Loss.....	7.1	5.5	5.0	4.5	4.2
Mechanical Efficiency.....	85.0	88.0	89.0	90.0	91.0

The last set of results was obtained by plotting the others as a curve and taking a more advanced point from that curve.

The data necessary to plot a complete curve of this nature being at hand, it is believed that this appreciation of mechanical efficiency and depreciation of horsepower loss will reach a high point or peak at or near 250 degrees outlet temperature, the statement of a well-known authority on cooling to the contrary. With this temperature it would be easy to maintain efficient lubrication, which could not be said for more advanced degrees of heat. In this connection it must be carried in mind that the temperature mentioned is that of the outlet and not of the cylinder walls which will be higher in proportion.

The whole seems to make out an excellent case for the use of oil, but, strange to say, with the exception of the two Western firms mentioned, a couple of French tractors and a few German builders of heavy cars, these advantages have not been put to a practical use, despite the many excellent features brought out. The one large redeeming feature of such use is the fact that it would cost nothing beyond the oil itself, and entails no mechanical complications. A pump is practically a

Fig. 18.—Efficient arrangement of both fan and flywheel in a unit.

necessity, but any car already so equipped may be changed over to an oil cooler in the length of time it takes to tell about it.

Natural or Thermo-Siphon Method of Cooling.—The thermo-siphon system of cooling depends for its action upon the fact that water when heated becomes lighter, and therefore in a large body of water the heated portion tends to rise or the cooler part to sink. Thus a change in temperature will cause internal action which, if carried far enough and with proper inlet and outlet pipes, will result in a continuous circuit—at least the circuit will be continuous as long as there is a source of heat. As indicative of the difference that the temperature makes, the table of relative volumes of water at different temperatures is given from maximum density to boiling point:

Temp. Fahr.	Volume.	Temp. Fahr.	Volume.
39.1	1.0000	122	1.0118
50	1.0003	149	1.0196
77	1.0029	176	1.0287
86	1.0043	194	1.0357
95	1.0059	203	1.0395
104	1.0077	212	1.0434

As a large difference in the temperature would be necessary to cause any considerable flow in a closed system, such as an automobile cooling system, the motor must necessarily be run rather hotter than the same motor and cooling system could be run with the water mechanically circulated. This is not only true, but the advocates of this method consider it an additional advantage of their system for the reason that a hotter motor is more efficient thermally and mechanically.

One very prominent advocate says that the engine is hotter when the water is boiling rapidly than when it is boiling slowly and it is a fact that because the water is absorbing more heat units proves not that the engine is cooler than before, but that it is doing harder work. It is certain that when the water is boiling very rapidly there is more difference in volume and more positive circulation than when it is boiling slowly.

Water Allowed to Boil and Steam Condensed.—The same authority goes on to say that he favors boiling water as the proper temperature and a gravity circulation as the proper method because this method insures a fixed temperature for the engine to work at. In this view he does not stand alone, for a prominent French house not only agrees, but has carried the principle still farther in practice. The Gillet-Forest system allows the jacket water to boil and produce steam. This is then condensed in the radiator. The cylinder jackets are kept filled by means of a float valve, which allows water to enter in such a quantity as to replace that turned into steam.

If the cooling medium is kept at any temperature below the boiling point this temperature will necessarily vary as the work varies. In the case of air-cooled engines this temperature will vary with the speed of the car, engine and the velocity of the wind. In the case of pump circulation, on the other hand, this will vary as the speed of the pump varies. With boiling water, however, this remains constant, permits of the finest adjustment of the mixture and the least amount of necessary variation in the point of most advantageous spark.

The rapid spread of this system in the past two years, previous to which it had but a couple of advocates, speaks volumes for the favorable results obtained. The very latest car announced, a small light car at a popular price, by one of France's most famous constructors, has used this system. While this particular case may only mean that the manufacturing cost on this specific model has been reduced as low as possible, its success on the light car will result in its adoption on larger models.

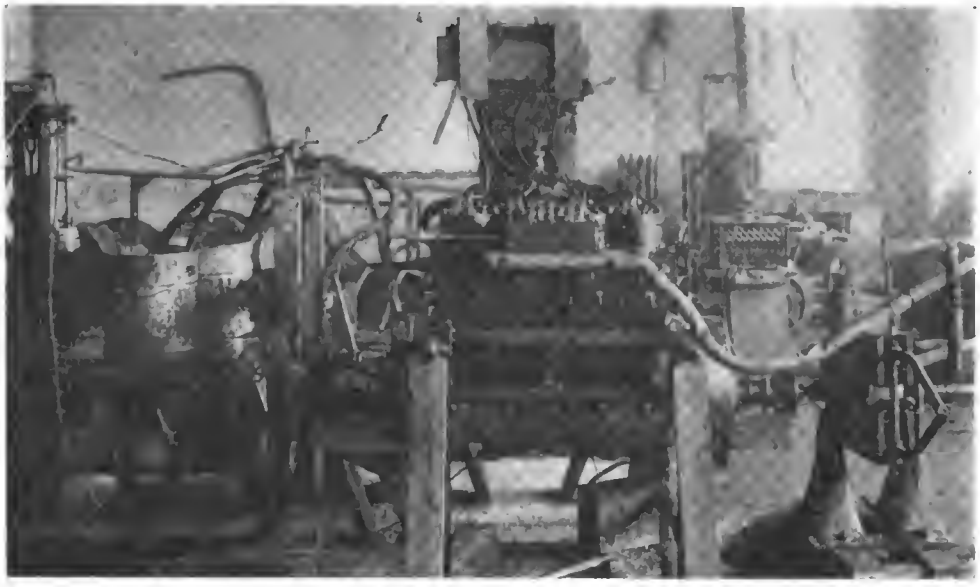

Fig. 20.—Oil testing apparatus ready for the test.

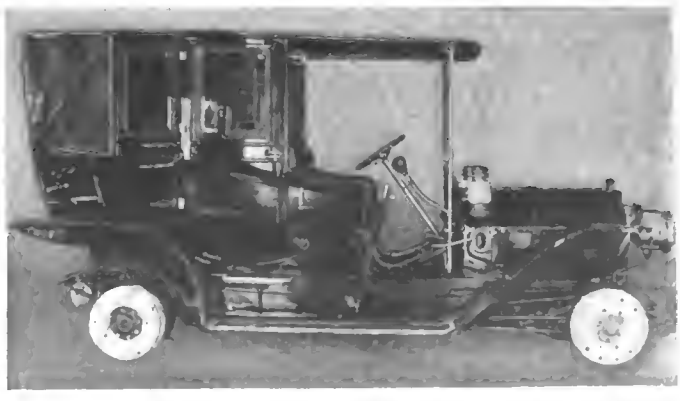
The direct cooling by means of air, forced or blown directly against the cylinder walls, which are increased in radiating power by the addition of fins, has many friends and, perhaps, many more enemies. The fact remains that it works and works continuously on several makes using this method. The French originally tried this way of cooling, and after testing it out, would have none of it. The fact is to-day that one would have to search France over pretty thoroughly to find a reputable manufacturer building air-cooled engines for cars only. That really proves nothing, but the fact that many American builders of that style of engine have been obliged to bring out a water-cooled model in addition, is good evidence of the attitude of the people toward it regardless of its theoretical or practical advantages.

NECESSITY IS THE MOTHER OF INVENTION.

INDIANAPOLIS, IND., April 5.—Necessity being the mother of invention, this fact is again illustrated in the accompanying photograph, which shows the expediency adopted by the Nordyke & Marmon Company to get a large Marmon landaulet through a low door into its salesrooms in Indianapolis.

The 36-inch wheels were removed and 18-inch wooden wheels, with cotton belt tires, were substituted, the car then being driven, by its own power, over pavements two squares, and into the building to its place. The large expanding brake shoes, 17 inches in diameter, had only ½ inch clearance.

The Marmon salesroom is a large, well lighted, finely appointed room in the new office building of the Central Union Telephone Company, corner of New York and Meridian streets. This location is to be permanent, and the company has also secured splendid quarters, within one-half block of the salesroom, for storage of demonstrating cars, and with every facility for the care and attention of the cars of Marmon customers.



Wooden Wheels on Marmon that Passed It Through Low Door.

Some Aids in Proper Care of Tires

By Stillman Taylor.

THE pneumatic tire is a very pertinent subject for discussion, and while much has been written upon the choice of size, proper inflation, and care of the "rubber tube," this subject is by no means generally given the careful attention it deserves. That the average owner and driver is very prone to treat with careless indifference this important detail of the car, is very apparent to any observer who is at all familiar with the subject. Why this should be so, is something of a mystery, when we consider the very large amount annually invested in tubes and shoes. Although it is an almost universal custom to lay the blame upon the manufacturer when anything happens *en tour*, it does not necessarily follow that the tires are defective. Indeed, the real source of trouble is far more likely to be found with the driver himself, and may be often directly traced to lack of proper care and abuse. The manufacture of pneumatic tires has long since passed out of the experimental stage, and a score or more concerns are to-day turning out tires that are as near mechanical perfection as the best materials and skilled labor can produce.

Common Causes of Rapid Wear.—While a tire may be injured in a variety of ways, the common causes of rapid wear may be said to be due to improper and insecure attachment, careless driving, and hard service. Any one or all of these things may contribute to shorten the life of the tire. Rim cutting, blowouts, and excessive tread wear are unmistakable evidence of careless driving and may be greatly lessened if not entirely avoided by proper care. Punctures and deterioration caused by chemical action or rotting of the fiber, may also be reduced to the minimum by taking certain precautions.

Selection of Tire Sizes Is Very Important.—That the owner may get the most mileage out of his tires, it is important that high grade tires of ample size be first selected. To equip a car with cheap tires is to invite trouble, which for very obvious reasons also applies if the tires are overloaded. A certain amount of reserve strength is necessary for servicability, and unless an amply large size is selected for the work called upon to perform, much annoyance and expense may be expected.

Forty per cent. reserve strength may be calculated sufficient for average driving, but 50 per cent. will not be found wanting when a bad piece of roadway is encountered. It is much better to allow a bit extra than to start out handicapped and "under shod." As the rear wheels support some 75 per cent. of the total load, it is highly important that the driving wheels be provided with tires of generous size.

Too Free Use of Brakes.—A too free use of the brakes is perhaps the commonest source of tire wear. With the exception of those occasions when it is imperative to check the car as quickly as possible, the use of the brake should be dispensed with. Braking is greatly overdone by most drivers, and the habitual use of powerful hand brakes cannot but prove harmful to the tires, owing to the sliding of the wheels which ensues before the momentum of the car is overcome.

Learn to control the car's speed by the throttle and spark and prolong the life of the tires by closing the throttle, disengaging the clutch and allowing the car to coast to a stop. By all means avoid the nefarious practice of bringing the car to a stop by letting the tires rub against the curbing. This slipshod method cannot be too strongly condemned, inasmuch as it rapidly wears out the shoe, loosens up the tread and allows dirt and water to work in to rot the fabric. Driving in car tracks is bad practice, which brings undue wear.

How to Prevent Blowouts.—That bugbear of the autoist—the blowout—may be largely done away with by keeping the lugs screwed up tightly. This is necessary to prevent any side play of the shoe within its rim. Loose lugs not only permit the tire to creep and roll out from the rim when rounding a curve, but the side play is often sufficient to completely shear off the valve stem. For the sake of safety, if for no other consideration, too much attention cannot be given to the tire fastening, and the lugs should be frequently examined and any looseness taken up, both before and after a run.

Rim cutting is generally caused either by overloading or lack of sufficient inflation. If the tires are called upon to carry a greater load than their dimensions are calculated to bear, no amount of pumping will keep them from flattening under the excessive load. This invariably results in the cracking and breaking down of the tire at its weakest point—where the flange engages the clinch. Badly fitting or misshapen rims are productive of the same ill effects as overloading.

Rusty rims are likewise to be avoided, and they should be occasionally gone over and cleaned of any rust that may have accumulated. A coat or two of enamel will often prevent further corrosion, or the rims may be given a coat of wax. This is the better method, and is the only satisfactory way of treating the rusty rims of an old car. To make a thorough job, the metal should be well scraped and sandpapered. The wax (preferably beeswax) should be heated and applied in a liquid state. The wax will not injure the rubber in the slightest, and by keeping out the air prevents further rusting of the metal.

The surface of the rim which comes in contact with the inner tube should be smooth. If rough, it is likely to wear and damage the tube, in which case the rim should be wrapped with a layer or two of tape, the loose ends being cemented in place. This tape may be obtained at any dry goods store.

Precautions to Be Taken After an Accident.—Excessive wear may be attributed to several things, as bad cuts, side slip, excessive braking, and speeding. Accidents are apt to occur to the most careful drivers, and upon such occasions the tire should be replaced at once. A small hole in the shoe will need no repair other than sealing up the aperture with rubber solution. This should be done before dirt and sand have a chance to work inside. In case a tire cannot be repaired on the road and an extra one is not at hand, it should be removed and the rim wound with three or four turns of rope, the ends being fastened to the spokes. Or if preferred, the tube may be removed and the casing filled with rope; this being accomplished by removing one side of the clinch and winding the rope around the circumference of the rim inside the casing. Care should be taken that there is enough clearance for inserting the flange in the clinch of the rim. This will give the requisite support and keep the casing from undue flattening and cracking of its retaining walls.

A convenient way for locating nonparallelism in the steering wheels is accomplished as follows: Turn the wheels in position for straight ahead running, and measure the distance between the front rims or tires. This measurement should be taken at the height of the hub and at the back of the wheel. Procure a stick and mark the spots between measurements. Now push the car forward until the front wheels make one-half a revolution, and take a second measurement at the same point (this will be at the front of the wheel, owing to the half turn forward). If the wheels are parallel, the two measurements should correspond. If there is a variation, the obvious remedy is to take up the lost motion in the parts.

Speeding Has a Very Destructive Effect.—Speeding is another cause of tire wear and the friction created by high speeds will often heat the metal rim uncomfortably hot for the hand to bear. A liberal use of talcum or soapstone will do much to prolong the life of the tire, acting as a kind of lubricant between the inner tube and casing.

Information for the Man Who Drives

EVERY once in so often, the exact time varying with the quality of the original finish and the conditions of use, it becomes necessary to have a car repainted, if it is to maintain a presentable appearance. Ordinarily such work should be entrusted only to an experienced carriage painter, but the excessive charge frequently assessed by such professional talent, often much greater in amout than is asked for an equivalent amount of work on horse vehicles, have caused more than one autoist, especially among the owners of the lower-priced cars, to essay the task without expert assistance.

In deciding to venture upon an amateur job of automobile painting, however, there are several points to be considered. First, it must be understood at the outset that it is not practicable to undertake a high-class coach finish for a number of reasons. Such work requires a great deal of time, not merely in applying the paint and varnish, but in waiting for the various coats to dry and in rubbing them down with polishing materials. The amateur will be wise to satisfy himself with one of the many excellent prepared paints, with the varnish admixed, such as are sold for painting wagons and carriages. These are obtainable in everything but the gray automobile finishes, go on smoothly and dry quickly. It is particularly important that only the best qualities be used, and the highest price that it is possible to pay is a good guide to quality, as well as being economy in the end, because of the superior quality of the high-priced paints. Brushes, too, must be of the very best, since any others will shed bristles on the work and ruin it. No paint with linseed oil in it is to be used, because of the tendency of this oil to cause cracking. If the paint requires thinning, use pure turpentine. Two coats of the right sort of paint should be sufficient.

Of the utmost importance is the preparation of the surface for painting. The least preparation that can be tolerated is to sandpaper down the old paint, evening off all rough edges, and following this by removal of all grease with kerosene and gasoline. Better than this, however, is to remove all paint, which can be most easily and quickly done by some of the chemical preparations sold by the paint manufacturers, thus avoiding the laborious methods of burning and scraping, or the injurious use of lye compounds. The preparations referred to are applied with a brush, and in a few minutes the paint swells, loosens and comes off, a second application hastening the operation.

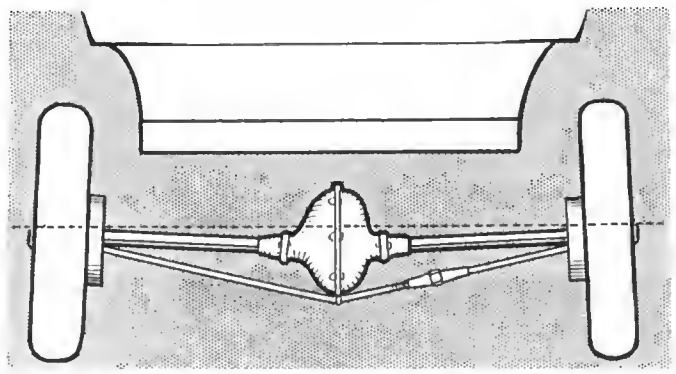
Striping is a work that ordinarily will justify the employment of an expert carriage painter for a half day, though a man with a steady hand and some preliminary practice, or with the simple striping machines now on the market, will find it surprisingly easy to achieve a very fair result.

Use for Railway Air Hose.—It is not widely advertised by the railway companies, but it is no less a fact that the air hose used to connect the air-brakes and train signal systems of adjacent cars can be made to constitute an excellent substitute for an unserviceable water connection on almost any standard automobile. As is extensively known, these connections generally are made of large-size rubber hose, and are given to leakage and wear as a result of prolonged use. A Western motorist recently found a section of such hose from a freight car that stood on a siding, the solution of a serious dilemma, which might have resulted in a long walk and then a delay for shipment of large enough hose, had not the railroad company thoughtfully provided the cure for his difficulty in the manner stated.

Consideration for the crew of the way freight will dictate that the required few inches of hose be cut not from the middle but from one end of the air connection, thus leaving it possible still to utilize what is left. For the same reason, if more than one connection is required, the different pieces should be cut from different cars, so as not to shorten the quota of any one unduly. And, of course, the honesty of the average autoist will suggest that the railroad be remunerated by a check, or, better, an anonymous contribution, forwarded to the proper officials.

Adjusting Truss Rods.—With standard types of shaft-driven autos, the normal straightness of the rear axle is, in most cases, maintained by a truss rod, pinned at its ends to the axle tube, bowed at its center by the bevel-gear housing and made adjustable for length by a turnbuckle.

It is inevitable that from time to time such an axle will require readjustment, no matter how well it may be designed or constructed. The long-continued terrific hammering over road inequalities, whether or not it is accompanied by slight wear of the pins and eyes, and at the point of contact with the bevel-gear housing, is almost certain to sag the axle to a greater or lesser extent at the center. On the other hand, contact with a rock or other obstacle in the road may bend the truss rod, thus shortening



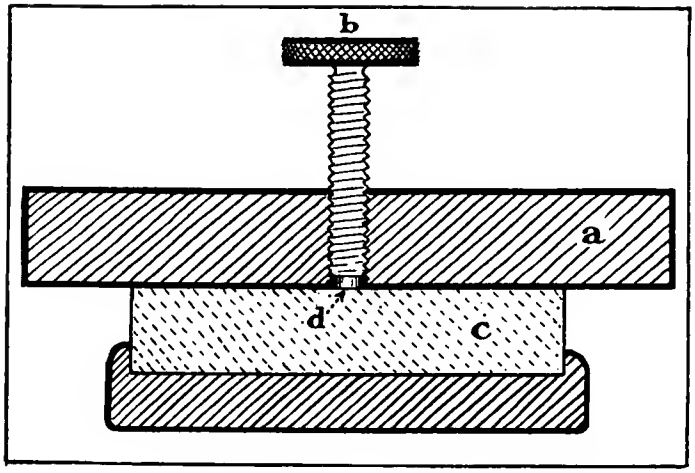
Showing Simple Method of Straightening Axle.

it and throwing the center of the axle up. Either deviation from a straight line is apt to be attended with disastrous consequences—loosening and wear of the rivets by which the axle tubes are held into the housing, wear and breakdown of the floating-axle members, or cutting of the bevel and differential gear teeth.

Bad as it is to run an axle that has become slightly out of line from either of the causes mentioned, a greater danger exists in the frequent ill-advised methods that are employed to effect readjustment, and which often result in a worse condition.

The proper way to secure a correct adjustment is to sight a board or other straight edge against the axle, as shown in the accompanying sketch, thus making it impossible to leave the axle out of true as the result of working the turnbuckle. It is to be noted that the turnbuckle invariably is provided with a lock nut, which must be loosened before adjustment is attempted and set tightly up when it is completed. Beginning with a new car, as the truss rod is adjusted now and again it will come to need adjustment less and less often, unless because of accident, the metal seeming to stretch to a natural limit.

Grinding Fixture for Vibrator Contacts.—In the maintenance of a car equipped with a jump-spark ignition system involving the use of vibrator coils, it becomes very important from time to time that the vibrator contacts be reground to remove the pittings and inequalities occasioned by the unavoidable slight arcing between them. With platinum-iridium contacts of the hest quality, the effect of such arcing is reduced to a minimum, but with contacts of poorer quality, it requires frequent atten-



Section Fixture for Grinding Vibrator Contacts.

tion. In any case the problem of securing a perfectly flat and even facing off of the small circular faces of the contact points is one that will trouble the average autoist considerably, as, indeed, it troubles many a very fair machinist. A simple solution of the problem, however, is the use of a grinding fixture approximating the lines of the accompanying sketch, in which (a) is a flat metal plate perforated with a threaded hole for the reception of the trembler adjusting screw; (b) bearing the contact at its point, and (c) is an oil stone for effecting the resurfacing. With this device, the finest possible adjustment can be had of the amount of metal removed, while at the same time the new surface is kept at exact right angles to the axis of the screw.

THOMAS TEST SHOWS EXCELLENT RESULTS.

LAFAYETTE, IND., April 5.—A recent unofficial test of a big Thomas car was made at Purdue University to satisfy the owner's curiosity as to what it would do on the testing stand. The car was a 1909 model 4-60 Thomas Flyer, rated by the manufacturers at 53-horsepower. The motor has a bore of 5 3-4 inches and a stroke of 5 1-2 inches. On the testing stand the drawbar pull, speed and horsepower delivered at the wheels were measured each time and a large number of readings were taken. That is, at certain fixed drawbar weights the speed and power were measured. A few of these readings taken at random are given, these being selected so as to show the possible variation in power with the speed:

Drawbar pull in lbs.	Max. speed in M.P.H.	Horsepower at Wheels.
150	82	32
250	53	36
300	48	38.5
On the second gear, the above being on direct drive		
660	24	41
On the first or low gear		
1,050	13.2	36

The car was geared down 2.23 to 1. The greatest power was developed on the second, which is intended as the hill climbing speed. This was 78 per cent. of the A. L. A. M. rating, a very high rate of efficiency.

After the test the owner, A. L. Sheridan, expressed himself as very well satisfied with the car's performance. No special preparation was made; the car was simply driven over to the laboratory and tested, so that the results here given are not exceptional.

AUTOMOBILE STATISTICS FROM AUSTRALIA.

Consul-General John P. Bray, of Sydney, transmits the following detailed information relative to the importation of motor vehicles into Australia:

According to a customs return recently issued, 3,559 motor vehicles were imported into Australia from 1901 to 1907. Of this total, 1,175 went to New South Wales, 1,436 to Victoria, 132 to Queensland, 496 to South Australia, 224 to Western Australia and 96 to Tasmania. The total import value of these vehicles was $3,392,125, and the duty paid on them amounted to $701.105.

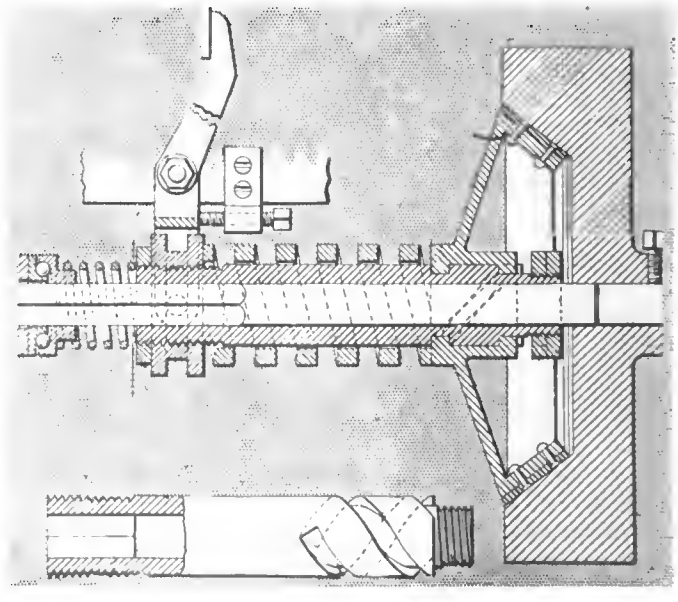
Of the total number of automobiles imported during the years stated, no less than 398 were imported from the United States. In the year 1903 the United States sent to Australia 71 automobiles, valued at $35,262; in 1904, 161, valued at $75,586; in 1905, 122, valued at $63,799, and in 1906, 44, valued at $37,841. The figures for 1907 are not yet complete, nor is it possible to get the figures for the first three quarters of 1908.

Bodies for automobiles, motor trucks and wagons, valued at $135,011, were imported during the same period, the duty amounting to $45,954. There were further imported during the nine months under review chassis for automobiles, motor trucks and wagons of a total value of $933,394, and the duty upon these amounted to the total sum of $22,439.

A NEW ONE IN CLUTCHES.

Anyone who has ever heard the taxicabbies mesh gears will appreciate to the fullest extent any device designed to ensure easy or gradual clutch releasing. The newest idea in the clutch line comes from Morris Ireland, of New York City, and his invention relates to a clutch between two shafts, which automatically releases upon a predetermined load being applied to the driven shaft whereby damage may be prevented.

More particularly it relates to an automobile clutch in which the road shocks are not transmitted to the engine when the clutch is engaged, and the breaking of the gears in changing speed and reversing as well as in starting is prevented. For instance, the driver frequently attempts to start upon too high a gear, which strains the gears, slips the wheels with damage to the tires, or overloads the engine. By means of this invention, in case the vehicle is started at too high a speed, the engagement is automatically released to such an extent as to permit a certain amount of slip between the driving and driven shaft, and thereby the vehicle starts slowly and without straining. The clutch being engaged, it will be seen that the driving torque tends to revolve the clutch cone on the worm backwards and the big spring opposes this force, thus tending to balance it and permit the small spring to hold the clutch in engagement. If the backward component exceeds the forward component the clutch member will be rotated on the sleeve, causing it to screw through the clutch cone until the operating collar has drawn the lever against the set screw, which causes all movement to stop. When this has taken place the clutch member will rotate backwards along sleeve away from clutch, thus causing disengagement. It can thus be seen that the clutch disengages gently as well as engages gently, which is an important advantage of this invention. The adjusting screw allows of a variation in the spring tension, which may be experimented with until the clutch "floats" on the shaft.



Section View of the Ireland Easy Release Clutch.

Letters Interesting and Instructive

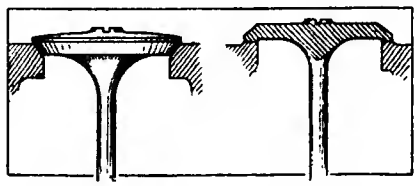
FLAT-SEAT VALVE ADVANTAGE.

Editor THE AUTOMOBILE:

[1,817.]—Please advise me through "Letters Interesting and Instructive," what are the advantages and disadvantages of square seated valves. I understand that a square seated valve is now being used exclusively on a number of the highest grade imported cars. CHARLES J. CHABOT.

Dallas, Texas.

The statement that these valves are used on a number of imported cars is subject to proof, as is also any statement of the advantages. In both types the volume of the opening is equal to the circumference of the effective opening times the



Cone Seat Valve. Flat Seat Valve.

sine of the angle of the valve seat times the lift. In the flat seat construction this angle is 90 degrees and the sine is 1. With the taper seat the angle is usually 45 degrees and the sine is .707. From this it is seen that for the same effective opening and lift the flat seat gives a larger volume of gas than the cone seat in the ratio of 1 to .707. This is utilized by reducing the lift in the same ratio, which ought to give a more quiet action. Users of this type of valve claim that the form reduces the amount of corrosion, and therefore the regrinding necessary.

IN RE MAGNETO WINDINGS.

Editor THE AUTOMOBILE:

[1,818.]—Please tell me through "Letters Interesting and Instructive" how to calculate the size and number of turns of wire for a magneto such as the W. & S. to give an amperage and voltage great enough to run an ordinary spark coil as used on automobiles, the magneto to run three times the normal motor speed. Also, please tell me the voltage and amperage necessary to run an autombile spark coil.

Chicago, Ill. L. E. B.

(a) The electromotive force impressed in the secondary circuit of a spark system may be as high as 30,000 volts.

(b) The current in amperes, at this high voltage is probably very slight. If the source of supply will afford 50 watts, the current will then be $50/30{,}000 = 0.0016 =$ current in amperes.

(c) If the secondary conditions are as above stated, it is then possible to say if the primary circuit will hold to a slightly higher wattage, in view of the losses in the coils, and if 60 watts is taken as the primary value, the same rule will work to find the current, *i.e.*:

$$60/5 = 12 \text{ amperes.}$$

(d) In the above, if the measurements are taken, as for an alternating current in one case, the same measurements must hold for all, and in view of the irregular shape of the waves of electromotive force, it will be understood that there can be much uncertainty to contend with.

(e) The primary current in amperes, as given, looks a little high, but it will be remembered that this does not mean 12 amperes out of the battery, which gives a direct current, and there is a correction to be made which might bring the direct current down to about 8 amperes, on a basis of 5 volts, electromotive force.

(f) The calculation of the windings of a magneto must take into account the design of the magnetic circuit, which would take much more space than can be given in the "Letters," but it is proposed to publish an article on this subject within a few weeks. In the meantime if you can use the formula of the electromagnetic induction class, it will be possible to make some headway through the use of the same, which is given as follows:

Considering a rotor of a dynamo electro machine, of which the magneto is a type, the formulæ, in a general way, may be written:

$$E = \frac{t\,s\,\theta}{10^8} \quad \ldots\ldots (1)$$

$$t = \frac{10^8\,E}{s\,\theta} \quad \ldots\ldots (2)$$

$$s = \frac{10^8\,E}{t\,\theta} \quad \ldots\ldots (3)$$

$$\theta = \frac{10^8\,E}{s\,t} \quad \ldots\ldots (4)$$

When,

E = Electromotive force in volts;

t = Turns of wire on the rotor;

s = Speed of the rotor in revolutions per second;

θ = Total of the magnetic flux, passing across one air gap between the rotor and the polar face.

From the electromotive force as found above the drop in volts in the windings must be deduced, and the balance will be available for useful work. In a magneto, it is probable that fully one-half of the impressed voltage in the windings of the rotor will be lost, due to the resistance of the wire used in winding the same. The problem is one in which it is the aim to wind as many turns as possible, of the wire of the least possible resistance in ohms, taking into account the greatest possible speed of the rotor, and the highest attainable flux (magnetic) density in the airgap. Consult a table of double cotton covered copper magnet wire, to determine space required for the windings.

GASOLINE MILEAGE RECORD.

Editor THE AUTOMOBILE:

[1,819.]—Please advise me what car holds the record for the greatest mileage on one gallon of gasoline and what the record is?

San Antonio, Texas. C. H. DEAN.

In the two-gallon efficiency contest held in New York City May 5, 1906, a Franklin 16-horsepower car carrying two passengers made 87 miles, which is 43.5 miles per gallon. The system of figuring adopted gave the Franklin first place, while second went to a Frayer-Miller car with five passengers, which covered 47.9 miles, an average of 23.95 miles per gallon. If, on the other hand, the award had been based on the number of ton-miles or passenger-miles, first place would have gone to the Mack observation car, which carried 19 people 17.13 miles. This works out 8.56 miles per gallon, but the passenger-miles per gallon would be 171.3, against 119.75 for the Frayer-Miller and 87 for the Franklin. The ton-mileage per gallon was 39.94 for Mack, 39.16 for Frayer-Miller and 32.62 for Franklin.

Your question brought out the point that mileage alone is not the only desirable feature, and we have gone into this at some length to prove that point. To our knowledge, no similar contest has ever been held, nor have these figures been exceeded.

STANDARDIZATION OF PARTS.

Editor THE AUTOMOBILE:

[1,820.]—It has been stated that the Licensed Association has done a great deal of standardizing of automobile parts. Will you please tell me just what they have done in this line.

Port Jervis, Pa. H. A. MORRIS.

The association has made only a small start toward standardization thus far, but it hopes to do more in the future. In fact, aside from the yoke ends, which were standardized as a matter of getting lower prices on forgings, screw threads, nuts, bolts and screws, little or nothing has been done towards the really important matters of standard wheels, axles, control parts, etc. As for the fine-screw threads, this really is a complication, for there previously were accepted standards, and the one added in no way conformed to those. Of all the subjects worthy of investigation, prior to standardization, no one is more meritorious than the control. Any man who has ever driven in a strange car will appreciate the full force of this. What was the spark advance before is now the retard, the reverse is actuated by the movement which formerly threw in the low speed, and many other inversions which are sure to be a source of trouble.

Some work has been done towards standardizing spark plugs, but the new standard created much trouble in that it was different from all previous sizes. A little

work has been done on wheels and rims, while the engine rating formula was a help, but the real big problems of standardization have not been touched as yet.

TO FIGURE RADIATOR SURFACE.

Editor THE AUTOMOBILE:
[1,821.]—Will you kindly tell me how to figure the radiating surface for an automobile engine, using the tubular form of radiator?
Pottstown, Pa. G. S. H.

A very good empirical rule for this is: multiply the bore by the stroke, times the number of cylinders, and the result will be the number of feet of length of 3-4-inch tubing necessary. To use 5-8-inch tubing, add 1-5; for 1-2-inch tubes, add 1-2; while for 3-8-inch tubes, it will be necessary to double the original figures, and for 1-4-inch size, to triple them.

All this is for tubes spaced three times the diameter apart, and not more than five tubes deep.

So, if you want to figure for a 4 1-2 by 5, four-cylinder engine, you will multiply $4\ 1\text{-}2 \times 5 \times 4 = 90$ feet of 3-4-inch tubing. Then to use 3-8-inch size, multiply by two, giving you 180 feet. By the rule you are limited to 1 1-4 inches center to center. If your space restricts you to, say, 18 inches high, that will allow of 14 spaces, or 15 tubes. For five tubes deep, the limit by the rule, this would give a total of 75 tubes. To have 180 feet of length with 75, you must have them $180/75 = 2$ feet 5 inches long. If your car will not allow this length, you must use a larger sized tube.

SERIES MULTIPLE ADVANTAGES.

Editor THE AUTOMOBILE:
[1,822.]—In a recent issue of your magazine, The Automobile, was an article advocating the use of batteries in series multiple for purposes of economy. Will you please advise me whether the coupling of a series of new batteries with a series of partly used batteries will cause deterioration in the new ones, and if so, whether the used batteries will appreciate in the same proportion as the fresh ones deteriorate?
New York City. E. C. D.

The writer of this paper made the point, as you will notice if you read it again, that the other cells will build up one dead one in discharging through it, with no appreciable losses. If this takes place in one series, why would not the same thing take place with a weak series connected in series multiple? Reasoning forward from this, it is apparent that partly used cells could be used with new ones without excessive depreciation on the part of the latter.

KNIGHT MOTOR AGAIN.

Editor THE AUTOMOBILE:
[1,823.]—I have heard considerable about a new engine called the Knight. Can you tell me anything about it and where I may obtain a good description of it?
Charlestown, W. Va. J. H. DONOVAN.

The Knight engine has the ordinary valves replaced by two sliding sleeves. This was described very fully in THE AUTOMOBILE for October 22, 1908, on pages 572-573. In this week's issue is given a description of a French two-cycle motor with a sleeve in place of valves on the same principle as the Knight.

EXHAUST GAS AND RUBBER.

Editor THE AUTOMOBILE:
[1,824.]—Please advise what is the effect on rubber tires, and what would be the result of using the gas from the exhaust for inflating tires by means of such a contrivance as mentioned in your issue of March 25 under the name of "Maxim Tire Inflation Apparatus."
Zanesville, O. J. B. MORRIS.

The principal constituents of the exhaust gases are carbonic oxide, whose presence indicates incomplete combustion, carbon dioxide, and nitrogen. It is thought that both of the former have a bad effect on rubber, although this has never been proven. If this is not so, the use of the gases for tire inflation would have no injurious effect. That this is the case may be inferred from the fact that some of the tire companies are putting out tanks of compressed carbonic acid gas for this purpose. The other components of the exhaust vary, and some of those occasionally present have a bad effect on tires or any form of rubber. Thus, oxygen is sometimes present and rots rubber. The hydrocarbons, when on hand, act just as does any oil. Others have no bad effect on the fabric, but readily pass through it, so that they only temporarily inflate the tire.

POWDER PREVENTS FRICTION.

Editor THE AUTOMOBILE:
[1,825.]—Is there any way in which the heating of tires can be prevented or lessened, particularly on long runs? I have often worried about this, for on long Summer tours my tires would get so hot that they were uncomfortable to the hand.
Portland, Ohio. A. B. SEE.

This cannot be wholly prevented, but can be lessened very materially by introducing some antifriction powder between the shoe and the inner tube before starting on a long run. Then, in case you have to stop with a puncture, it is a good idea to put in more powder. Some use ground talc, known as talcum powder. Others get a stick of soapstone and rub it over the shoe or tube, or both. There is mention in this issue of a new form of powder for this purpose which is neither talc nor soapstone. Be sure never to use oil, which attacks rubber.

NAPHTHALENE AS CAR FUEL.

Editor THE AUTOMOBILE:
[1,826.]—I read in your editorial, "Fuel Economy Is a Live Topic," in the March 25 issue with a great deal of interest, especially since I have been endeavoring for some time to run my engine more economically. Your figures, 62 per cent, are startling; but do you consider naphthalene blocks adaptable for use on a pleasure car? I have been laboring under the impression that gasoline was the ideal, as well as the most available, fuel for this purpose, and I would appreciate some advice through your "Letters Instructive" department.
New York City. J. L. HERTRAIS.

Naphthalene blocks are fully as applicable to touring cars as to trucks. In the case of the latter, however, economy is the keynote of all truck installations and, consequently, must be of their operation. To sell a truck at all you must first convince the man that it will save money.

The plan might well be worth a trial, but you must remember that gasoline will still be necessary for starting purposes. Gasoline is a good fuel, but the supply is decreasing in the face of an enormous increase in the number of consumers. This will necessitate the use, in the near future, of some other fuel, primarily not quite as good.

HONEYCOMB RADIATOR AREA.

Editor THE AUTOMOBILE:
[1,827.]—Please advise me what area of air space per square foot of frontal area I should get in buying a high grade honeycomb radiator, and how this figure is arrived at?
Pittsburg, Pa. JOHN R. DAVIDSON.

As to the figures you request, 9,000 square inches should be the minimum for a really high-grade cooler. This is figured as follows: inside circumference of tubes times the number of tubes, times the depth of the radiator, which is really the length of the tubes. This will give the total air space area. Now figure the frontal area of the radiator and divide the total air area in inches by the total radiator area in feet and the result will be the air surface per square foot of frontal area. With a square tube, the method is the same, but the length of the square plus the depth times two will replace the circumference in the case given above. If the sides of the tube are corrugated, the length of the corrugated line will have to be figured accurately.

REACTIONS OF ACETYLENE.

Editor THE AUTOMOBILE:
[1,828.]—Please advise what chemical reactions occur when pure compressed acetylene gas explodes from concussion, without the presence of oxygen? What fluid is used in acetylene gas tanks to absorb the gas, which I believe is not a trade secret? What is the essential chemical used in the various decarbonizers? Carbon is usually considered as insoluble, is it not? If so, it would seem as if the action of a decarbonizer was merely the breaking down or dissolving of the binding agent between the particles of carbon and the metal, and then mechanically blowing out these particles. Is this so?
La Salle, Ill. V. A. MATHESON.

The first named reaction is impossible. Although acetylene is regarded as unstable it cannot change its chemical composition without some other element to combine with, as it cannot of itself break down. The formula for acetylene is C_2H_2, and when it combines with air or burns the reaction is expressed as follows:

$$2\,C_2H_2 + 5\,O_2 = 4\,CO_2 + 2\,H_2O.$$

The usual solvent for the compressed gas is acetone or pyroacetic acid, which has the chemical formula $3\,(CH_3)\,O$. Your understanding of the action of decarbonizers is correct.

PATCHING CELLULOID.

Editor THE AUTOMOBILE:
[1,829.]—Some time ago I noticed in Letters Interesting and Instructive" a recipe for patching the celluloid windows in an automobile cape top. But now on wanting the recipe, I cannot find it. Will you kindly give it to me?
Ludington, Mich. M. E. CARTIER.

We do not find the recipe in question, but as acetone is a solvent for celluloid, get a little of that and apply it just as you would any cement.

FRENCH ROTATING SLEEVE TWO-CYCLE MOTOR

THE Ledru two-cycle motor was brought out some time ago, but the excitement incident to the introduction and use of the Knight motor has again drawn attention to it, says Louis Lacoin in Omnia. This motor has no valves but just as the Knight has two sliding sleeves, which take their place, so too, this has a single sleeve which replaces valves. There is this difference, however; in the Knight motor the sleeves reciprocate as the piston does and are driven off of the camshaft by a pair of eccentrics, while in the Ledru engine, the single sleeve rotates, being driven by a worm on a special shaft.

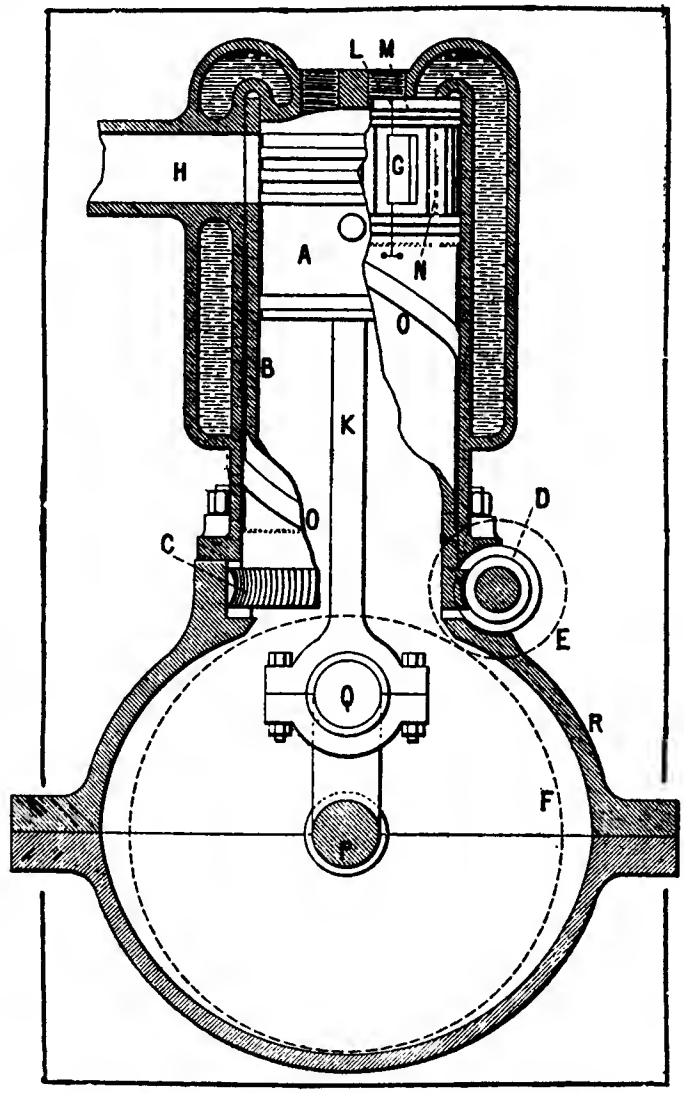
The figure shows a section through the cylinder and exhaust pipe, the inlet not being shown. *A* is the piston driving through the connecting rod *K*, the crankshaft *Q*, of which the center of rotation is at *P*, the split in the crankcase *R*. Upon the crankshaft is mounted a gear *F*, meshing with the gear *E*. The shaft which carries the latter also has a worm *D*. This drives the worm gear *C* which is fixed to the sleeve *B*. In this manner the proper speed of rotation (which in this case is a reduction) is obtained, as is also the rotative motion itself. This rotating sleeve has at its upper end a series of three slots or ports which the turning motion brings successively to register with the inlet and outlet, the latter being shown at *H*. These ports are marked *G* in the figure.

A series of circumferential grooves *M* and longitudinal grooves *N* are used to retain the tightness, no rings being provided. Near the top of the sleeve, and running from each slot to the top as well as some distance below, are cuts, marked *L* in the illustration. To reduce the friction to a minimum, the walls are cut away or relieved up to the immediate region of the inlet and outlet. To go farther would be to endanger the gas tightness which is questionable even with the construction shown. The engine is water jacketed, and the head of this presents a depression very similar to the Knight engine.

In operation the sleeve carrying the three equidistant ports must turn during a complete cycle of the motor through such an angle as will bring one of the ports at the end of the stroke to the place occupied by the port immediately before it. This being the case, it must turn six times more slowly than the crankshaft, a cycle corresponding to two turns. If, then, the motor runs at 600 revolutions per minute, the sleeve must run 100 r.p.m.

The position, size and spacing of the ports together with the speed of the sleeve are such as to follow any predetermined timing. In this way is attained a result never before reached in a two-cycle engine.

Lubrication and cooling seem to offer no difficulties, although in the problem of gas-tightness is a source of real trouble, perhaps the only one, of any consequence. This marks the only real apparent advantage of the Knight over the engine in question, the gas-tightness of the former being beyond question. As to the friction of the rotating sleeve, the point is made that this is less than it would be with the same sized sleeve reciprocating, because the unit pressure is the same in both cases, while the surface must be greater with the sliding sleeve. It is also apparent that the power consumed, aside from friction, is less, because the weight of the sliding part is not started and stopped with every revolution. This is an entirely new and original idea which seems to possess much merit. The whole story can only be told by thorough practical experience.



Section Through Ledru Motor Showing Sleeve.

At the annual general meeting of the Imperial Automobile Club of Germany, it was announced that at the commencement of the year the club possessed 42 honorary, 12 life, 1,240 ordinary, 51 women, and 349 extraordinary members. The expenditures amounted to $89,460, the income to $89,831. only leaving a sum of $371 to be carried over. This small sum, compared with $31,295 in the previous year, is due to the non-holding of a motor show in 1908. The club issued 5,200 triptyques for the United States, France, the Netherlands, Austro-Hungary, Italy, and Switzerland, nearly 2,000 more than in 1908, while up to now 2,318 danger boards have been distributed among the affiliated clubs at a cost of about $525. It was also announced that the club is interested in the "Automobile Traffic and Training Roads, Ltd.," to the tune of about $60,000.

The three-point handicap in the Prince Henry Tour regulations has been protested by several of the big South German clubs, and the Society of German Motor Manufacturers and Traders has also stated its disapproval of so sweeping an embargo, which will keep a number of experienced amateurs away from the start. As the propositions have been, however, out for so long, the Society thinks it best not to absolutely upset the race by a protest, but there will be an alteration in next year's race, the third and last of its kind.

Krupps of Essen, the great German firm of gunmakers, have just concluded a series of tests with a gun destined to burst balloons. The trials ended most satisfactorily. They are also building a new repeating gun to be fitted into an airship.

TOURS FOR REAL TOURISTS CERTAIN OF POPULARITY

By W. C. MARMON.

WITH the passing of Winter and its blizzards, bad roads, high winds and other inconveniences that make touring anything but ideal, and with the incoming of Spring, bringing numerous pleasures to the automobilist, naturally the car owners' thoughts are centered on the various tours and race meets which will be held during the warm Summer months.

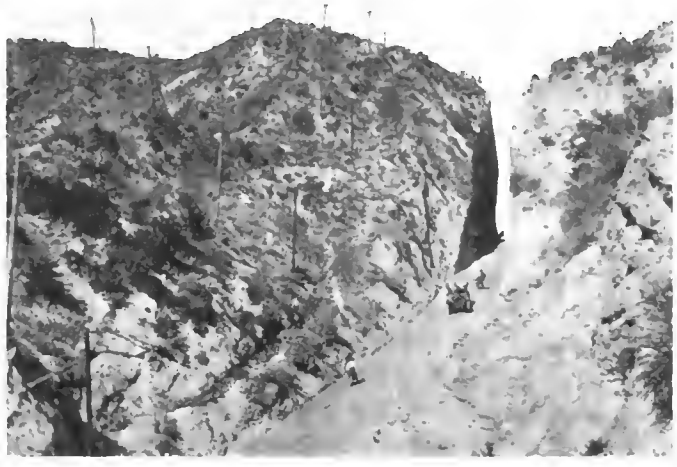
That 1909 is to be a banner year for the automobile industry, not only from a manufacturing standpoint, but from one of pleasure, sport and pastime, has been evidenced by the shows. Manufacturers are exerting every effort to meet the heavy demand made on them by the dealers. Dealers are being practically deluged with rush orders from the buyer; and the mails and telegraph and telephone wires are burdened with messages begging for earlier shipments and asking for additional consignments.

"There will be a shortage of cars," is the statement daily heard along "automobile rows" of the big cities. Manufacturers were unprepared for any such great demand for cars as has been the case since the American Motor Car Manufacturers' Association started the first of this year's shows in the Grand Central Palace in January. The other big shows which followed the Grand Central Palace affair have added to the makers' burden of keeping pace with the demand.

All this means that there will be thousands of new owners, and as new blood and new enthusiasm become mingled with the old, there is bound to be more individual touring and more interest and a larger list of entries in the competitive events.

It would appear that 1909 will see a record-breaking number of tours of all classes, but instead of having all tours of a competitive nature, with set schedules and long daily runs, why not have national tours similar to that held last Summer through fascinating New England by the Automobile Club of America?

Such enjoyable tours as these would create a great deal of interest. There is no question but what there are many owners who believe in and would enter such tours and who do not care to participate in a more strenuous contest such as the Glidden Tour. A tour running without schedule, in other words, a go-as-you-please event, would arouse interest, especially with women and children. It would arouse interest in the territories through which the great caravan of cars passed.



Picturesque Fremont Pass in Southern California.

This noted mountain pass in the San Bernardino Range is 28 miles from Los Angeles, at an altitude of 1,770 feet above sea level. The grade of the road is 45 per cent. and the sides of the walls of the pass are 70 feet high.

While such a tour would not necessarily demonstrate the good and bad points of a car for the benefit of the manufacturer, such as is the case in the Glidden, it would demonstrate to the buying public and prospective buyers that the present day car can travel under regular touring conditions over all manner of roads.

If such events are held it would mean that the entrant could stop whenever and wherever he liked, could eat his lunch in the shade of stalwart trees or in a hotel. It would mean that women and children would not become tired out with the day's journey, and that the country and scenery could be better enjoyed than if the car was traveling under schedule and had to arrive at controls at a given time. The elimination of penalizations would leave the mind of the drivers and passengers free to enjoy every bit of the journey.

Many members of the American Motor Car Manufacturers' Association are in sympathy with such tours, and believe that they would instill into the entrants a firmer belief in the automobile and the joys of touring would be better exemplified.

INCREASE IN EXPORTS OF AMERICAN AUTOS.

WASHINGTON, D. C., April 5.—In the monthly summary of the Department of Commerce and Labor, published for the month of February of this year, an increase in the number of automobiles exported is noted, while at the same time there has been a decrease of the amount of imports over that done in the same month of the previous year. In the matter of imports there were 59 automobiles brought into this country last February, as against 79 in 1908, the total value decreasing by $34,610, the figures being: 1909, $128,190; 1908, $162,800. The average for the month of this year is $2,172.71 per car. Of the countries sending cars to the United States, France leads with 33, Italy is second with 13, Germany third with 12, and England is represented by 1. There were no other nations on the list, and this is true also of the month of February, 1908. The falling off is shown by the statistics for last year: France 60, Italy 15, Germany 3, and again England 1. There has been an increase, however, in the importations of parts for foreign automobiles, the figures being: 1909, $61,579; 1908, $36,173.

American-built automobiles to the number of 208 were shipped out of this country during the month of February, an increase of 57 over those sent away in that month of last year, and the average value of this year's product was $1,668.11. The total value was $346,967, as against $301,240, but there were less spare parts needed by American cars this year than last, as shown by a falling off of the value of these by $2,285, the amount sent out this year being valued at $44,839, or $16,740 less than the amount of foreign parts imported. Of the exportation, British North America took by far the largest part, nearly one-third of the total going to Canada. This is the way in which the various countries, leading in the importation of American cars, stood last year: England, Italy, British North America, France, other European countries, West Indies, Mexico, and smaller ones. The change in the standing for 1909 is shown thus: British North America, England, Italy, West Indies and Bermuda, Mexico, France, South America, other European countries.

As far as numbers of cars are concerned there was no change in the exportation of foreign cars between the two months, both registering four, but there was an appreciable difference in the value, for in the recent February the total value was $20,009, as compared with $14,100 for 1908.

AIDS IN THE EXPORTATION OF AMERICAN AUTOS

THOUGH many American automobile manufacturers are at present unable to supply the demand for their product in this country, yet there are concerns looking forward to a time when perhaps there will be a lessened demand here, and these have gone into foreign fields. The United States consular service has been instructed to report frequently upon the conditions in the various countries as to the opportunities for the sale of American automobiles, and the following reports may be found of interest and advantage in building an export trade.

Good Car Demanded by Natives of Bombay.

Consul E. Haldeman Dennison, of Bombay, makes the following suggestions relative to the introduction of American motor cars into India:

The American automobile is little known in India, and still has to prove itself the equal of the Continental makes used. There are now 1,000 cars registered in Bombay, and not one of these is of American make, with the exception of a few "cripples," the remains of a lot of cheap runabouts which were dumped on this market some years ago. This market is well worth the best efforts of American manufacturers and exporters. Among the well-to-do natives the automobile has become popular, and the Continental manufacturers have been reaping a rich harvest from the ever-expanding trade. The native as a rule is unfamiliar with machinery and desires a car that is going to give him the least trouble possible. He is quite willing to pay a good price for a superior machine, and American exporters would do well, when they really determine to exploit this market, to introduce only their best machines.

There is only one road in India that approaches the standard of those in Europe and that is the "trunk line" between Bombay and Calcutta. This would seem to give the American car some advantage, as it is built to negotiate even the roughest sort of roads. Until American manufacturers are ready to expend considerable time and money in developing their trade they might as well not attempt to enter this market, as the writing of letters and sending of catalogues is a waste of time.

America Not Represented Among Many Cars in Burma.

In stating that there are nearly 150 motor cars in Rangoon and probably 50 more at other places in Burma, Consul E. A. Wakefield gives the following trade particulars:

These cars are, with a few exceptions, made in England, selling at prices varying from $500 to $4,000. One French car cost $6,000. A few years ago an American one-cylinder car was sold in India, which gave very poor satisfaction. To-day there are no American cars sold in the province of Burma and to successfully reintroduce them it would undoubtedly be necessary to practically demonstrate their serviceability and durability in a most thorough manner.

It is very questionable if American manufacturers could sell a car here without having the machine on the spot to be thoroughly tested. One car in successful operation would be worth more here than all the correspondence and advertising matter they could send. The roads in and near Rangoon are excellent for touring, so that the number of cars in use is steadily increasing. This is true of Mandalay, Moulmein and Bassein to a more limited extent. If an American manufacturer could secure a Rangoon firm of unquestioned reliability to act as his Burma agent it should be easy to secure a foothold which would lead to a continually increasing business. [A number of Rangoon firms which might represent automobile builders are listed at the Bureau of Manufactures.]

Large Field for Hill Climbers in Portugal.

Vice-Consul-General Charles F. La Serre, of Lisbon, has the following to say about the introduction of American automobiles in Portugal:

There are in Portugal about 1,200 automobiles. Nearly 600 of these are registered at the Governo Civil of Lisbon. Lisbon is a city of over 400,000 inhabitants and of considerable wealth. The automobile business is growing rapidly, and if the American manufacturer intends to make a bid for the business, now is the time to do it. There is only one American automobile in Lisbon; this is a runabout and is in the hands of an agent newly established. One reason why there are no more American cars here is that American concerns have not displayed any energy in demonstrating their machines in this market. Again, the dealers hesitate to try cars of American make because an automobile was imported three or four years ago that did not meet with the requirements demanded here. Lisbon is very hilly, and cars that are used here must be climbers. The lowest horsepower required is 15-20. There are no electric cars or cars of the steamer type in use in Lisbon. It is the experience of the dealers that the former are not suitable for hilly country, and recharging is very expensive.

There are some German and English automobiles sold here, but the favorites are the French and Italian makes, the French being the most popular. The style of car mostly used is the double phaeton or touring car. They vary in price from $1,800 to $5,000. The import duty is comparatively low. According to a recent government report there are in Portugal 8,920 miles of macadamized roads and 2,461 miles in construction.

Tires a Prominent Factor in Australian Trade.

Consul Henry D. Baker, of Hobart, makes the following suggestions to manufacturers of automobiles and parts who desire to share the trade of Tasmania and other Australian States:

American manufactures of automobile tires, if they desire to cater to the trade in Tasmania, should make the goods destined for this market of millimeter sizes and should have their goods shipped with greater care than at present. Most of the cars in use in Tasmania are of British or French make and are all equipped with metric-size rims. It is easier here to get good English or French tires than American tires; even the owners of American cars have nearly all gone to considerable expense in having the rims on their wheels changed to metric sizes. American manufacturers should supply tires in conformity with the sizes in local use and should take care that their goods reach Tasmania in good condition. Their goods might then be sold not only for American cars, but for British and French cars as well.

A common fault with American tires on Tasmanian roads is that they blow out around the edges, due to deterioration of the rubber on the long transit out here, the tires not having been placed in the coolest and driest places possible on the freight ship. The English and French tires arrive in much better condtiion, being shipped with a notice, "Do not stow near boilers." Owing to the present poor reputation of American tires here, those manufacturers who wish to improve their trade should be liberal in their guarantees and be willing to replace tires which prove faulty or damaged in transit. The sizes most commonly in use in Tasmania are the 880 by 120 or 125 millimeters (the last two being interchangeable with the 880 rim), 820 by 120 or 125 millimeters, 760 by 90 or 100 millimeters, and 815 by 105 millimeters.

Road Improvement for Autos in Afghanistan.

Consul-General William H. Michael, of Calcutta, furnishes the following information concerning the proposed establishment of an automobile postal service in Afghanistan:

It was reported some months ago that the Amir of Afghanistan intended to improve the roads en route from the Khyber to Kabul, in order to permit the use of automobiles. Orders have just been issued that the section from Dhakka to Jellalabad is to be taken in hand at once. The idea seems to be to establish an automobile postal service to and from Kabul, but progress is likely to be slow in this matter, as heavy expenditure will be required on the hill section between Gandamak and Buthak.

American Cars Have Large Sale in Java.

Consul B. S. Rairden, of Batavia, replying to an inquiry from an American manufacturer, has the following to say about the sale of automobiles in Java:

Within the last two years sales of automobiles have rapidly increased in Batavia and adjacent districts of the Javanese capital. The importations of automobiles in 1905 amounted to $48,000, and in 1907 to $360,000. The agent for an American automobile company reports that he sold over 100 cars in twenty months. The machine he handles sells for about $2,000. [The addresses of Batavia automobile dealers are on file in the Bureau of Manufactures.]

Large Demand for Cars in Other Countries.

Similar reports from other consular stations indicate that throughout Asia, Africa, and parts of Europe, there is a growing demand for automobiles which might readily be filled by those made in this country. Both European and Asiatic Turkey need light cars with ample power and hill climbing ability, such that will carry five people, with engines of from 15 to 20 horsepower. The best is required, however, and demonstrations must be given by operators who are able to show the quality of the cars.

STANDARDIZATION VITALLY NECESSARY.

Standardization of automobile parts has become a most vital question, and one that now is worthy of the most conscientious attention. This is a matter that affects the owner and driver more than the factory man, because it will cost the latter much money to make changes of this sort. On the part of the buyer, however, there should be no hesitancy in demanding such reforms as standard control systems. There should not even be any necessity to call attention to this, as it is self-evident to anyone who has ever driven two different makes of cars.

In one, the forward movement of the lever on the outside gives the low speed. Get into another car, get into crowded or congested streets, and then upon involuntarily throwing the outside forward speed, instead of going slowly forward the car goes backward into another rig, and the driver, probably a very careful operator, has a bill of damages to pay. And all through no fault of his own nor through any lack of care or ability.

Then there is the matter of the spark and throttle. On one car the former is uppermost, on the next the throttle is above. In the habit of driving the former, you retard the upper lever, and when you crank the motor it throws you over into the next county. Result, doctor's bills and other expenses through no fault of your own.

Moreover, the number, location and operation of the foot pedals are worthy of standardization. When used to operating the clutch with the left foot, it is more than disappointing to apparently declutch and try to change gears, only to find that the left pedal operates the brakes. So, instead of declutching you have put on the brakes and spoiled your gears.

That the importance of this subject is partly appreciated by the buying public is apparent from the statement that one of the foremost American car builders, turning out one of, if not the finest car in the country, was obliged at the beginning of the present season, by outside pressure, to change the form and location of the gear shifting lever. The former position was a good one and the shifting arrangement was excellent, but the public would not have it. As a result, the distinctive position was abandoned in favor of the commonly accepted one.

So, too, with the progressive gearset, this was markedly simple, comparatively lower priced to construct and install. But most of the people wanted and would have the other form and it became in a sense the standard. This necessitated that many firms change their construction, which has been done to a great extent, until to-day there is but one very prominent firm using this form of gear box, and, if rumor can be believed, even that will be changed for next season.

Instances might be cited, ad infinitum, but that is unnecessary. The idea is that many of the present forms which automobile parts take should be so altered, not to be interchangeable, that would be asking too much, but to be standard so that the operation of all cars will be alike. Then, and then only, will the danger and worry, with consequent expense, be eliminated.

This millennium can only be brought about by a strong and urgent demand from the people. To make such a demand efficacious, it must be widespread or universal. Previous to that must come a full realization of its advantages and the disadvantages now existing.

* * *

THE DIFFERENCE IN THIS YEAR'S CONTESTS.

There will be races this year, there is no question about that, but there will be a decided difference and it will be apparent to even a casual observer. Racing in the past has been racing pure and simple, sport for sport's sake. The contests of to-morrow will not be races in that sense of the word, but will be more tours on the order of a modified Glidden tour, which will be useful and serve a purpose in pointing out the good, bad and indifferent forms of construction as "shown up" by many miles of running under the ordinary conditions of road, speed, wind, weather, etc.

The other form of races which will be brought before the public in the coming season will also be of a useful nature, but at the same time more on the order of races. Just as the first named class will show up defects in the course of ordinary running, so the second class will do the same under extraordinary conditions of speed, road, etc. So hill climbing contests with maximum speed prevailing, two-mile track speed races and limited road races will be in order. Just as the British Four Inch race was a very instructive one to manufacturers, by far the most instructive ever held, so similar contests, properly arranged and run, may be expected to be of equal benefit to American manufacturers. The contests of the coming and future years will be of this nature.

HIGHWAY COMMISSION HEARS ABOUT CHAINS AND NON-SKIDS

ALBANY, N. Y., April 5.—Not a single voice in favor of the prohibition of tire chains and non-skid devices was raised in the hearing before the New York State Highway Commission on Thursday last, while prominent automobilists from various parts of the State appeared in opposition to the proposed measures. By their forceful arguments it is probable that they influenced the members of the commission to allow the use of these devices with certain restrictions and regulations. Evidence was adduced showing that chains do little or no damage to road surfaces in wet weather and at the same time increase the safety of the occupants of automobiles, though it was admitted that chains and other non-skids should not be used in dry weather because of possible injury to both tire and highway.

Charles Thaddeus Terry, chairman of the legislative board of the American Automobile Association, was the principal speaker against the proposition. Mr. Terry said that tire chains and other adequate non-skidding devices are necessary for safety and careful operation of automobiles when roads are wet, slippery or covered with snow and ice and that the injury to the road from them, if any, is slight and far overcome by the necessity for public safety.

"As for the tire chain," he said, "it sinks into the tire and only slightly in the road, is easily removed and thus is used only in dry weather. There would be no objection to a statute prohibiting the use of non-skidding devices when the roads are dry, for that is the only time when they can do any damage and automobilists do not need them."

Mr. Terry said further that a prohibition against the use of tire chains in all conditions of the road would be unconstitutional and that the Supreme Court of this State had held such a restriction void; that the provisions of the New Jersey law allowing non-skidding devices only when there is an inch of snow or ice on the road had been condemned by the attorney-general of that State and had been practically repealed by the New Jersey Assembly by a large majority. "All the automobilists of the State and of the United States," he declared, "insist that a prohibition of the chain would deny to automobilists equal rights to the use of highways, because under many decisions of the court it has been held to be a natural and usual use."

Coker F. Clarkson, representing the Association of Licensed Automobile Manufacturers, said: "What is the possible injury due to the use of chains? Only a fraction of the automobiles in operation ever use chains. Those on which chains are used have them in the tool box nine-tenths of the time—probably only one day in a month are chains used for a short time. Is it possible that this small use can really be the cause of material damage to the roads? During the very small time relatively that chains are used, what happens? On the straight stretches, when running free, the wheels are in perfect rolling contact with the road. The chains are loose on the tire treads, and imbed themselves partially in the tread of the tire and partially in the road. If the road is soft, the chains will compact a small area of it. If the total area of the road could be similarly treated, it would be greatly improved. Thus, far, no objectionable feature is present in the use of chains. On the contrary, every horse that passes, every moment it is on the road, is digging into and disintegrating the road. In addition, it would be well-nigh impossible to start a car on winter roads without the use of chains."

Henry Edmund, of London, England, a member of the Institute of Civil Engineers, said that he had much experience with the use of chains abroad, that in some parts of England they are required by law because the effect of chains upon roadways was less injurious to the roads than steel-studded tires, which had been experimented with.

Others who appeared were: H. A. Meldrum, president, and Oliver A. Quayle, ex-president, New York State Automobile Association; Frank G. Webb, president, and H. G. Andrews, secretary, Long Island Automobile Club; Bert Van Tuyl, Automobile Club of Rochester; F. H. Elliott, Bronxville Automobile Club; G. H. Stillwell, Automobile Club of Syracuse; F. A. Kately, Mount Vernon Automobile Club; Albert A. Shattuck, ex-president, Automobile Club of America; George C. Diehl, engineer of Erie County; Hiram Percy Maxim, Hartford; Peter D. Kiernan, Albany; Arthur F. Phelps, Watervliet; John M. Bruce, Yonkers; Edw. M. McMahon and James Hemstreet, New York.

When the opposition, the automobilists, had finished their arguments, Chairman Hooker, of the commission, gave those who were in favor of the proposed law a chance to speak, but no one appeared. Those who attended the meeting are inclined to believe that the commission was favorably impressed with the arguments of the automobilists. The absence of any champions of abolition of non-skid devices certainly diminishes the force of their argument—if they have any.

NEW YORK INTENDS TO REGULATE AUTO SPEED

CONDITIONS in New York regarding the reckless, injudicious, and criminal use of automobiles have brought about the formation of the National Highways Protective Association, to make a determined war against the persistent speeders and joy riders who have aroused the city authorities during the past week. A number of serious and fatal accidents have been caused by automobiles operated at a speed far above that considered reasonable, and an active crusade against the automobile "hog" is the result. This is supported by automobilists, the police, the professional chauffeurs, and others vitally interested, for the stigma of the wild driving has been felt by all users of automobiles in the vicinity of the metropolis.

The newly formed association has been incorporated under the laws of the State of New York, and its particular objects stated in its articles of incorporation are:

To prevent the improper and unreasonable use of the public highways and public roads and places by the owners or users of horses, carriages, bicycles, automobiles, and all other vehicles; to enforce and protect the rights of the members of this corporation and the public in the reasonable and proper use of such public highways, public roads and places; to endeavor to secure the construction and maintenance of good roads by public authority, and in furtherance and not by way of limitation upon the objects above enumerated; to endeavor to bring about reasonable and uniform rules and regulations for the use of the public highways, roads and places throughout the United States of America; to aid in the enforcement of laws in respect thereto, and so far as may be lawful to aid in securing any such changes or modifications thereof as may be found necessary or proper.

The plans for the campaign call for the stationing of twenty men on thoroughfares, used by automobilists, who will note the numbers of cars which are speeding. Where there is sufficient evidence convictions will be pressed, and for constant offenders jail sentences will be asked. By a card index system an account of the law breakers will be kept, and after being reported to the headquarters, the owners of the cars will be notified, so that if their chauffeurs have had the cars out without permission they will be apprehended. If, on the other hand, the owners themselves have been indulging in bursts of speed, the notice may tend to prevent recurrences. It is thought that by this means joy-riding may be stopped, and one of the greatest evils wiped out, at the same time making all chauffeurs more careful.

One contention that will undoubtedly be successful will be the efforts to prevent young boys from driving horses in crowded

streets, who, it has been declared, cause nearly as many accidents as reckless automobile drivers. The safeguarding of pedestrians, and sane users of the highways, is a worthy object, and the national association has already been praised by the police authorities. The bicycle squads in the city have been reorganized, and additional men put on, until the wave of criminal driving subsides. The detectives who are put upon the trails of the guilty will be no respecters of persons, and those who usually have enough influence to "beat" their cases will find that the influence will be of no avail.

Charles S. Whitman, a former judge of the court of general sessions, has been retained as counsel, and will have charge of the prosecutions for the society. The officers are: President, Henry Clews; vice-president, A. D. Middleton; secretary, Edward C. Cornell; treasurer, Gilford Hurry. Besides these officers, the incorporators are: F. Augustus Schermerhorn, Cleveland H. Dodge, George W. Burleigh, R. Fulton Cutting, Joseph H. Coit, Frederick N. Lawrence, Everitt P. Wheeler, J. Forbes Potter, Lawson Purdy, William H. Llewellyn, Milton I. D. Einstein, Ackley S. Schuyler.

CONNECTICUT MAY HAVE A COMMISSIONER.

HARTFORD, CONN., April 5.—Legislative action regarding automobile laws is at present in a peculiar situation, for a bill has been presented providing for the appointment of a commissioner of motor vehicles, and it is stated that until this bill is either accepted or rejected the proposed automobile legislation will not be considered. Therefore affairs are at somewhat of a standstill. The commissioner, if appointed, would look after the enforcement of the present automobile law or its successor and would issue the licenses and certificates of registration. At present this is done by the Secretary of State's office. There is considerable opposition to the new measure, although automobilists are generally in favor of it. If action is taken on the commissioner matter the present law may be revised. Another amendment likely to pass is one requiring registration of autoists from other States. This is opposed, and will be fought, unless it recognizes licenses of States which reciprocate those of this commonwealth.

ILLINOIS MAY EXAMINE AND LICENSE.

CHICAGO, April 5.—Examination of and licensing of drivers of automobiles in Illinois is contemplated by Senator Dellenback, who has introduced a bill which provides for the examination and licensing of all persons driving or operating motor vehicles propelled by electricity, steam or gasoline.

If this amendment passes it will also amend the motor-vehicle act so that all cities and towns in the State will be privileged to examine drivers and also to license them. Chicago evidently anticipates favorable action on the Dellenback bill, for its city council already has passed an amendment to the revised municipal code which in addition to the examination feature also provides for each car carrying a city tag. At present this extra tag cannot be carried without violating the State law.

STATE LAW FOR GEORGIA AUTOMOBILISTS.

SAVANNAH, GA., April 5.—Automobiles in the State of Georgia will probably soon be regulated by a uniform law which is now being prepared by the Secretary of State Philip Cook. Members of the general assembly have requested the drafting of the bill, and it is expected that it will be introduced into the Legislature at its next session in June. Mr. Cook has copies of a number of Northern State laws and is endeavoring to take the best parts for use in the Georgia statute.

HEARING TO-DAY FOR NEW YORK BILLS.

ALBANY, N. Y., April 5.—It has been arranged by the chairmen of the Senate and Assembly committees on internal affairs to hold a joint session on all bills relating to automobiles in any way before their committees for Thursday next.

OVERLAND BUYS POPE-TOLEDO FACTORY.

One of the largest automobile real estate deals which has taken place in this country for some time was consummated in New York, on Tuesday of this week, when papers were signed by John M. Willys, president of the Overland Automobile Company, of Indianapolis, Ind., and Col. Albert Pope, president of the Pope Manufacturing Company, Hartford, Conn., for the purchase of the mammoth Pope-Toledo manufacturing plant, at Toledo, O.

The Pope-Toledo factory is one of the largest and best equipped automobile manufacturing plants in the United States. It comprises twenty-four buildings of modern construction, having floor space of 400,000 square feet and covering twelve acres. It contains hundreds of thousands of dollars' worth of modern machinery. With its present factories at Indianapolis and the new Pope-Toledo plant, the Overland Automobile Company will be one of the largest manufacturers of automobiles in the country. The output of the Overland concern will be practically unlimited, and the 1910 product will be broadened with a larger range of models and prices.

In speaking of the new deal, Mr. Willys says: "The growth of the Overland company has been so rapid that we were forced to look to larger quarters. While for many reasons we would like to have increased our manufacturing facilities in Indianapolis, the Pope-Toledo location is the only one in the market which meets our requirements. When we secured control of the Overland Automobile Company we knew that the concern would grow, but did not expect that it would enlarge with such rapidity and in such a short period. Between 1903 and 1908, during the experimental days of the Overland, 250 cars were sold. During 1908 more than 500 Overlands were built and delivered. With only three months of 1909 passed, 1,350 cars have been built. and to-day we are 1,500 orders behind. The success of the Overland has swept us off our feet, and we were simply forced to secure larger quarters. The headquarters of the concern will remain at Indianapolis."

BIG MARATHON VICTOR WAS A CHAUFFEUR.

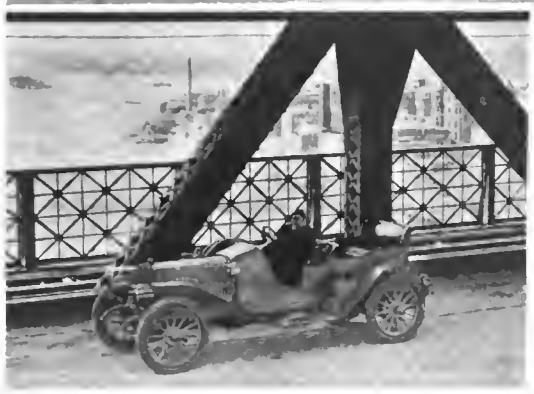
Chauffeurs may now take notice of a new road to fame, that of Marathon running on courses which take no cognizance of speed laws, for the style has been set by one Henri St. Yves. This youthful Frenchman made many thousand followers of this sport try to pronounce his name by winning the world's championship Marathon race in New York, last Saturday. It was heralded that he had been a waiter in the Hotel Cecil, in London, before coming to this country, and for that reason had given no "tips" upon his ability as a runner, inasmuch as he was in the habit of receiving only. It has developed, however, that the occupation of St. Yves was that of a chauffeur, and perhaps that accounts for his speed. His experience in his present line is a short one, covering but eight months, in which time he took prominent parts in four races in England and France, in which he scored a series of victories that have placed him in the front rank of the world's greatest runners.

GENERAL MOTORS COMPANY PLANS.

LANSING, MICH., April 5.—It was announced to-day by W. C. Durant, of the General Motors Company, who is visiting Michigan plants, that the new main factory of the General Motors Company is to be located at Flint, instead of at Lansing, as rumored. The new building will be 1,021 by 365 feet, and will be of brick, all under one roof. It will be located near the Buick plant, and represents an investment of $1,000,000. It is estimated that 3,000 men will be employed, in addition to the 5,000 now employed by the Buick company. It is intended to have the plant completed by early Fall.

It was also stated that the output of the Olds Motor Works will be greatly increased, and perhaps new buildings will have to be constructed this spring.

How New Yorkers Can Now Reach Long Island



METROPOLITAN automobilists, through the opening recently of the new Queensboro bridge between Manhattan and her sister borough, Queens, have acquired a short route to points on famous Long Island, doing away with the necessity of a roundabout trip to the Williamsburg bridge or the use of the now obsolete ferries. The saving in time will be very appreciable, for it is possible to leave the center of the automobile district and in a few minutes enter the gates of the Queensboro bridge, without having to go through congested traffic routes.

Incidentally there was a spirited contest among automobile dealers and owners to see what car would be the first to cross the bridge. White, Lozier, Franklin and others claim the distinction. Through the courtesy of the Department of Bridges a representative of the touring bureau of the White Company was allowed the privilege of driving his steamer over several hours before the roadway was formally opened by Mayor McClellan. The purpose of the trip was to secure data for those desiring to use the new structure, as it was believed that all autoists traveling between New York and Long Island City would make early use of the new bridge instead of the Thirty-fourth street ferry. The White touring bureau then issued the following circular of routes:

The best way for New York autoists to reach the new Queensboro bridge is to go through East Fifty-seventh street to Second avenue. Here turn left into Second avenue, and two blocks beyond turn right into the driveway of the bridge. The toll for an automobile is 10 cents, as on the other bridges. There is but one driveway on the new bridge, but it occupies the middle of the structure and is at least as wide as Fifth avenue. The bridge is 1 4-10 miles long.

On reaching Long Island City side, keep straight ahead through the plaza, and at the end of the plaza turn right into Jackson avenue. Continue on Jackson avenue until one block before reaching the court house, and then turn left into Nott avenue. One hundred yards beyond, bear left again into Thompson avenue, and continue over the new viaduct spanning the Long Island railroad yard. The distance from Fifth avenue and Fifty-seventh street to Thompson avenue by the route given is 2 7-10 miles. Thompson avenue, as is well-known to most automobilists, is the thoroughfare to all the principal roads on Long Island used by tourists. On returning to New York, retrace the route given except that, in leaving the bridge, it is best to go through East Sixtieth street.

Mayor McClellan, in crossing the bridge and officially opening it, rode in a Franklin touring car, but he was preceded by several hours by ex-Chief of Police Devery in his car. The Lozier comes forth, however, with the statement from C. A. Emise, of that company, that this car was really the first over, for Mr. Emise secured a special permit to use the bridge on Monday, the day previous to the announced opening, and that he crossed twice in his Briarcliff roadster. On going over en route to Flushing the main roadway was deserted and less than two minutes were consumed in covering the distance.

MOVEMENT FOR ATLANTA-WASHINGTON ROAD.

ATLANTA, GA., April 5.—Definite movements towards building a road from this city to the national capital have been started here, through the application of Frank Weldon and A. W. Smith for a charter, asking to be incorporated as the Interstate Highway Association. A capital of $1,000 is given, but the right to increase that to $100,000 is asked, and the objects of the association are stated to be several: the promotion, construction, and improvement of continuous highways from one section of the country to another; the right to organize local associations; to accept donations and contributions for the building of roads.

The principal office of the association will be in Atlanta, and it is planned to promote the road from this city to Washington before taking up those between other cities in the South.

COLUMBUS ASSOCIATION ORDERS ROAD SIGNS.

COLUMBUS, O., April 5.—The Columbus Automobile Association, which recently opened luxurious clubrooms at the Northern Hotel, has awarded a contract for the furnishing of a large number of danger and distance signs. The club will soon declare a "sign day," when they will be erected. For erection over garages twenty-five club monograms of blue have been received.

The club maintains a private secret service department, employing a detective to recover stolen machines and accessories. Since this department was founded twelve stolen cars have been recovered and also numerous other articles. There is a standing reward of $100 for the arrest and conviction of any person bothering the car of a member of the association. Another feature of the association is the information bureau.

Cross the Country Mud-Plugs the Thomas

PATHFINDING for an international contest, of the transcontinental variety, in the Middle West, is one continual round of hearty receptions and celebrations, when it is not a case of plowing through deep mud, or running over dusty roads. This has been the experience of the crew of the Thomas car, which is marking out the route to be taken by the contestants, in the endurance run from New York to Seattle next June. The pathfinder is now near Kansas City, Missouri, and has found that automobilists, and everyone else in that great country, are looking forward to the time when the participants in the event will pass through.

The Thomas left New York on March 20, reached Chicago on March 30, and left on April 1 for St. Louis. On the first day it reached Bloomington, 130 miles, running over roads that surprised the crew by their excellence, in comparison with some covered in Ohio. St. Louis was reached on Friday evening, by making the longest run of the trip, 190 miles, and the roads were found to be good, until within 20 miles of the Mound City, but there were many places where they were misleading. The big car had a triumphal entry, with a dozen other cars in line, and the general enthusiasm exhibited by everyone surpassed that seen anywhere. Saturday was taken for rest and the general interest in the contest grew apace. Business and automobile interests raised a purse of $1,000, to be given to the car which reaches St. Louis first in the run, and in the evening a banquet was given in honor of the pathfinding crew, nearly 100 members of the St. Louis Automobile Manufacturers and Dealers' Association attending, and the Postmaster, Frank Wyman, gave a letter to L. W. Redington to be delivered to the Postmaster of Seattle. Governor Hadley shook hands with the crew, as the official send-off, on Sunday morning.

Two days were allotted for the trip across the State of Missouri, to Kansas City, and daylight of the first was consumed in running to Mexico, 50 miles short of the distance it should have covered. The roads were good, but twisted and turned, so that it was hard to keep the right direction, and the car had to retrace its course several times. Other delays were caused by fractious horses, and many times the car had to stop until the equines were unhitched and taken off the road. Unwilling to lose time, the crew pushed forward to Centralia.

Kansas City would have been reached by daylight on Monday if it had not been for the turbulent condition of the Missouri River at Glascow, where there were only two means of crossing—a ferry, which could not be operated on account of the rough water, and an open railroad bridge, 100 feet above the river. George Miller looked at the latter, but the wind was so high that it was deemed best not to attempt the bumping across. As an indication of the interest shown all through the West, on Monday morning Moberly automobilists actually kidnapped the pathfinders, and made them put that town on the route, necessitating a short detour.

The river was crossed late Monday evening, and the night spent at Blackburn, about 50 miles from the river. A terrific storm forced the tourists to stop, and it turned the roads into seas of mud. On Tuesday afternoon the car reached Kansas City, having taken seven hours to travel 74 miles, the last 30 being over good rock roads, but the others were through deep mud. The trip was resumed towards Denver on Wednesday.

Two entries have been announced, a Simplex by H. B. Brosel, Jr., general manager of the Simplex Automobile Company of New York; and a Stearns by Oscar Stolp, of New York, who will be accompanied by H. Davis Webster.

NEW YORK WILL HAVE 24-HOUR RACES.

NEW YORK, April 5.—Prospects for three 24-hour track races were promulgated to-day at a meeting of the Motor Racing Association, at the Automobile Club of America, resulting in the appointment of a committee to inspect the various courses around the city, and to secure the best. This organization of metropolitan dealers held two successful round-the-clock events last fall, on the track at Brighton Beach, but the cutting up of part of this into building lots will prevent its use again. The Aqueduct and Jamaica tracks will be considered, and a programme arranged at an early date.

A. C. A. SMOKER TO CONCLUDE CARNIVAL.

NEW YORK CITY, April 5.—The Automobile Club of America has extended its hospitality to the automobile trade and will give a smoker and entertainment as the concluding feature of automobile carnival week, April 26 to May 1. At this smoker the prizes will be distributed. Carnival headquarters have been opened by Secretary W. R. Lee at 1789 Broadway.

ANOTHER TRACK MEET ASKED FOR.

BOSTON, April 5.—The contest committee of the Bay State Automobile Association has requested a sanction from the A. A. A. for a track race meeting to be held on the Readville track on June 17. Memorial Day, May 30, has in the past been the date usually selected for the spring races at Readville, but it was impossible to secure that date this year. The track has recently changed hands and improvements will not be completed in time to permit its use before June 17. The committee of the Bay State Association is headed by Dr. J. F. Hovestadt.

MAXWELL NEARING 8,000-MILE MARK.

BOSTON, April 7.—Well ahead of the 7,500 mile mark, the Maxwell four-cylinder touring car, which is running to make a 10,000 mile engine-non-stop record, is expected to cover the required distance within the week. Shortly after noon yesterday it had completed the 7,500 miles, and at noon to-day was 400 miles beyond that. It is expected to pass the 8,000 mile mark before nightfall to-day.

ADAPTING THE THREE-TON TRUCK TO FARM SERVICE

CONYERS MANOR, nine miles from Greenwich, Conn., is one of the notable estates in the East, being not merely ornamental, but a great farm operated on a commercial basis. It represents 1,300 acres of reclaimed land and is the home of E. C. Converse. Aside from being a beautiful estate, it is typical of the great advancement which has been made in modern farming, and especially in the way of applying scientific and commercial methods to agriculture. Motor cars are common at Conyers Manor. Not only is there a large and well-equipped private garage for the several pleasure cars, but there is a separate garage for commercial vehicles, which it is proposed to use extensively. The basis of work in the commercial vehicle line, now on the farm, is a Packard three-ton truck.

E. C. Converse's Packard Truck Leaving the Manor for Town.

The principal work of the truck is in running back and forth between the farm and the town. Its regular platform body has a special grain body inserted inside the regular stakes. By removing this inside body when it is not desired to haul grain to Greenwich the truck is ready for use in its other work of carrying fertilizer, coal, machinery and general supplies. Mr. Converse is an enthusiastic advocate of motor vehicles for hauling and makes no distinction between hauling in the city and in the country. He argues that with suitable roads such vehicles as this truck are particularly well adapted to farm hauling. Their greatest efficiency is in the carrying of approximately full loads for long distances, with infrequent stops. Agricultural hauling meets these requirements exactly.

For partial loads and short distances, the extra speed over the horse-drawn truck, makes up for the small load and more than compensates for the abbreviated distance. In the matter of stops, the gasoline vehicle is at no disadvantage, either, for it can be stopped in a shorter distance, and stopped or started in a shorter time than can the equal sized horse trucks. This agility, more than offsets the advantages, if any, accruing to the horse.

INCREASING USE OF THE AUTO FOR HOSPITAL SERVICE

THE illustration shows a White steamer recently put into service by the Bellevue Hospital in New York City after a prolonged trial of speed, easy riding qualities and silence, the last feature being of equal rank with the first in the final decision. This is a well-known quality of steamers and of this particular make. The advent of automobiles into this service marks another *new* departure, and a startling one, as it was freely predicted a few years ago that there was one field that the auto would never invade. This was the one in which a conquest is now being made by the car shown. There have been ambulances before this, but they have been mostly electrics, until the manufacturers of that type of car have come to look upon this field as particularly their own. The present instance shows that they are not very secure in their position and that it is time for them to look to their laurels. With the invasion of this division by the steamer as well as the electric, it would be a very hard matter to pick out anything in which some form of self-propelled vehicle is not applicable, or in which there is not a form of commercial vehicle working.

One of the New White Steamer Ambulances for Bellevue Hospital.

A Good Stretch of Pennsylvania Highway Between Lancaster and Harrisburg.

PENNSYLVANIA'S GOVERNOR GIVES TROPHY FOR CONTEST

HARRISBURG, Pa., April 5.—Gubernatorial participation in automobile endurance runs is something altogether new and exceedingly pleasing to automobilists, and the Motor Club of Harrisburg is the organization which is the first to secure this honor. Governor Edwin S. Stuart, of Pennsylvania, a friend of autoists and an experienced tourist, has donated the principal trophy for the four-day endurance run of the club, to be held from May 3 to 6, and perhaps may take an active part in the first lap of the contest.

A route of about 700 miles in length has been selected, and the pathfinders have already mapped out the first half of it. The party, headed by Dr. J. R. Overpeck, of Philadelphia, last week covered the roads of the first and second day, from this city to Washington, and return. From Harrisburg the route leads to Gettysburg, where the first checking station will be established, after a short run through the battlefield. From this famous place roads through more historic country were taken, over the South Mountains, to Hagerstown, Md., where the noon control will be made. The next stretch is to Frederick, where the checking station will be but a short distance from Barbara Fritchie's house. The Cooksville route to the national capital has been selected. The checking station has been arranged for at the New Willard Hotel, on Pennsylvania avenue, where the Washington Automobile Club will give a reception in the evening.

For the second day the run will start toward Baltimore, over a road that will surprise many, for it is a beautiful boulevard, and one of the best highways in the country. The entire distance to Baltimore was especially delightful to Pennsylvanians who know what bad roads are. The entrance to the city is made through the business section, and the checking station placed at the fine quarters of the Automobile Club of Maryland, on Mt. Royal avenue. Leaving the city the route leads through Druid Hill Park to the Reisterstown pike, on a run to Westminster, thence to Littlestown, where a second control will be placed, continuing through Hanover to York, where a noon stop will be made on May 4. The next station is at Lancaster, after crossing the mile-long bridge over the Susquehanna River at Wrightsville. At Lancaster a turn is made for the final spin back to Harrisburg for the second night stop. The roads on the preliminary trip were found to be excellent everywhere.

The remainder of the route will be covered this week, going to Wilkes-Barre and Scranton, and then returning via Delaware.

In addition to the Governor's trophy, there will be a National Capital Cup, donated by the Washington automobilists.

Crossing the Columbia Bridge at Columbia, Pa., Which Is One of the Longest Railroad Bridges in the Country.

CLUBS PREPARE FOR THE SEASON'S FUNCTIONS

NORRISTOWN CLUB HAS SPLENDID HOUSE.

NORRISTOWN, PA., April 5.—After two years of meetings in hotels, or at the offices and homes of its members, the Norristown Automobile Club now has a completely equipped and furnished home of its own, situated on the Reading Pike, a mile and a half from the town, large enough to hold banquets, and at the same time so arranged as to be a cozy meeting place for a few members at a time.

The building of brick is constructed in a bungalow style, so that the second floor is really the main one, and a broad stairway leads to it from the ground. The entrance from the porches which surround it is into a large Bohemian hall, finished and furnished in Mission style, with a wide stone fireplace at one end. On the same floor, which is forty feet square, are the ladies' parlors, the governors' room, cloak room and steward's quarters. Polished hardwood floors, handsome rugs and deep window seats give a homelike appearance to the big room, while

New Home of the Norristown (Pa.) Automobile Club.

the ladies' quarters are daintily furnished. The ground floor is a big rathskeller, with its stone open hearth, polished kitchen and grill, and a room for the steam heating and pumping plant.

At the rear of the lot on which the clubhouse stands there is a temporary shed which will cover a score of cars, and it is the intention of the organization to build a permanent garage ultimately. The building itself, and the future plans, are all in the hands of the house committee composed of William B. Hart, chairman; L. E. Taubel, Andrew H. Root, Harry C. Wilson and H. C. Carney. The club is indebted for its present location to L. E. Taubel, the treasurer, who purchased the property when it was a farm, and induced the club to build upon it. A housewarming was held recently and was attended by automobilists from Philadelphia and miles around Norristown.

LOWELL PLANS TWO RACES FOR NEW COURSE.

LOWELL, MASS., April 5.—Rumors that Lowell would have another stock-car race similar to the one held here last year have been set at rest through the announcement by the Lowell Automobile Club that both a light car and a large car race will be held on a specially prepared course greater in length than the one for the previous contest as features of an automobile carnival week. The dates have been set for next September 6 to 11 and the two speed contests will be the most important happenings of that Labor Day week. At present only the preliminary arrangements are being made, but the members are ready to push the whole matter as soon as John O. Heinze, the president of the club, returns from New York.

In addition to the automobile races there will be motorcycle contests, bicycle races, motor boat races and aquatic sports upon the Merrimac River. The interest aroused by the stock-car event last year has assured the club of the substantial backing of all local influence.

ALBANY CLUB OUTLINES MOUNTAIN TOUR.

ALBANY, N. Y., April 5.—Touring for pleasure only, with no form of a contest, is the plan outlined by the committee of the Albany Automobile Club which has charge of the club's fifth annual tour. This year a route has been chosen that will undoubtedly be a favorite one, taking in some of the most picturesque parts of New England, with short daily runs and frequent stops for sight-seeing. In fact, there are no rules, and the participants may stop as often as they like. The committee requests that the club members all stop at the hotels and garages with which arrangements will be made to give minimum rates.

The tour will commence on Tuesday, June 22, with a run of 132 miles to Woodstock, Vt., covering some beautiful country through Cambridge and Salem. On the second day the run is to the Bretton Woods, 110 miles, through Lebanon, Groton, Plymouth, N. H., the Flume and Franconia Notch, passing Echo Lake. Thursday will be given over to going to the summit of Mt. Washington, and on Friday there will be a run of 116 miles to Portsmouth, N. H., through Crawford Notch and Intervale. On Saturday the run will be another short one, 64 miles, to Boston, over ideal roads and through wonderfully beautiful and historic country, skirting the shore. On Sunday the tourists will travel over Massachusetts' splendid highways to Springfield, 95 miles, stopping en route to visit the old Way Side Inn. The run of the last day is over a new and very picturesque route, following the Connecticut river northward, through Holyoke to Northampton, passing Mt. Tom, and then bearing left through Goshen, Windsor and Pittsfield to the finish at Albany. This run is 98 miles in length and the total distance to be covered in the six days of touring is 615 miles.

HUGHES NOW WILKES-BARRE PRESIDENT.

WILKES-BARRE, PA., April 5.—At the annual meeting of the Wilkes-Barre Automobile Club, held here to-night, the following officers were elected: President, James H. Hughes; vice-president, Guy W. Moore; secretary and treasurer, P. S. Ridsdale; governors, Thomas A. Wright and George W. Lewis. The racing committee having the annual hill-climbing contest on May 31 in charge will be George F. Lee, chairman; T. A. Wright, P. A. Meixell, W. E. Steelman, Dr. E. C. Wagner, Guy W. Moore and George W. Lewis.

President Hughes, in his address, advocated increased activity in good roads work, efforts to secure sane legislation for automobilists, opposition to excessive speeding and vigorously advocated building a road up the Wilkes-Barre Mountain out of the Wyoming Valley to replace the old Easton turnpike. This has an average grade of 12 per cent. and a maximum of 22, and is so steep that there have been numerous breakdowns and accidents upon it. A preliminary survey has been made for a road with an average grade of 6 per cent. and a maximum of 11, and President Hughes will work hard to get this built.

A. C. A. WILL RE-ELECT OLD OFFICERS.

NEW YORK, April 5.—The Automobile Club of America, at its annual meeting, to be held Tuesday, April 13, will re-elect all of its present officers, with the exception of the treasurer, as nominated by the board of governors. No opposition will arise, for the constitutional time limit for the proposal of another ticket has elapsed, and therefore the officers for the coming year will be:

President, Judge E. H. Gary; first vice-president, Henry Sanderson; second vice-president, William G. McAdoo; third vice-president, Robert Lee Morrell; treasurer, Alfred Ely. The three governors whose terms expire this year have been nominated to serve for three years more, constituting the class of 1913. They are Horace Porter, George F. Chamberlin and Colonel John Jacob Astor.

ACTIVE CLUBMEN OF MANITOBA.

WINNIPEG, MAN., April 5.—At the annual meeting of the Winnipeg Automobile Club the election of officers resulted as follows: Patron, Sir Daniel McMillan; honorary president, J. C. G. Armytage; president, R. M. McLeod; first vice-president, W. R. Bawlf; second vice-president, P. C. Andrews; secretary-treasurer, W. L. Wright; executive committee, E. C. Ryan, D. B. Sprague, F. R. Newman, W. C. Power, W. A. T. Sweatman, H. M. Belcher, and C. Newton.

A resolution was passed admitting women into full club membership on payment of an annual subscription of $1.

The surplus proceeds from the race meet held last fall were distributed between the various hospitals in the city, each of which benefited to the extent of $35.

The secretary reported the offer of a free site for an automobile clubhouse by a well-known real estate firm, and the offer was left in the hands of the executive committee for consideration.

Fourteen new members were elected, bringing the total close to the 200 mark. It is proposed to hold two race meets during the 1909 season, and to arrange an extended tour during the fall.

WAUSAUITES FORM WISCONSIN VALLEY CLUB.

WAUSAU, WIS., April 5.—Owners of automobiles in this place have decided to form an organization under the name of the Wisconsin Valley Automobile Club. Up to this time the owners have been content to be individual members of the Wisconsin State Association, but the number of machines is multiplying so rapidly that it has been found to be of more interest to form a separate club. It will be affiliated with the W. S. A. A. and the A. A. A. Its main purposes will be to secure legislation for good roads; to keep a check on violators of the laws, and to maintain guide posts. H. G. Flieth, cashier of the German-American bank, will probably be elected president. Neal Brown, president of the W. S. A. A., is a prominent resident of Wausau and will be a member of the local organization.

UTAH AUTOMOBILE CLUB WILL JOIN A. A. A.

SALT LAKE CITY, UTAH, April 5.—Directors of the Utah Automobile Club have decided to apply for membership in the American Automobile Association in order to bring the State organization into closer touch with national movements in automobile affairs and to hold race meets, hill climbs and tours under national sanction. At present the club is chiefly interested in the good roads work under the provisions of the recent enactment of the Legislature, by which it is hoped to establish a system of improved highways throughout the State. As soon as weather conditions become settled actual work will be commenced.

HARTFORD POSTPONES CLUBHOUSE IDEA.

HARTFORD, CONN., April 5.—It has been decided by the "new quarters" committee of the Automobile Club of Hartford to abandon temporarily the idea of securing a clubhouse and to remain at the Allyn House for the present. This will be taken up for definite action at the annual meeeting, which will be held April 14. A number of desirable locations for a clubhouse were inspected and several good offers received.

J. Howard Morse, former president of the Automobile Club, and Mrs. Morse have returned to the city after a two years' tour through Europe. After a visit they will return to Switzerland.

BERLIN, WISCONSIN, AUTOISTS ORGANIZE CLUB.

BERLIN, WIS., April 5.—The Berlin Automobile Club has effected a permanent organization and elected the following officers: President, C. M. Boettge; vice-president, T. S. Rumsey; secretary, Perry Niskern; treasurer, W. N. Crawford; executive committee, Frank H. Russell, H. Safford and Fred Wright. The headquarters will be at the Wilson Garage. The club already has a membership of 35.

THE AUTOMOBILE CALENDAR.

AMERICAN.

Shows.

April 10-17.....Brooklyn, N. Y., Clermont Rink, First Annual Automobile Show, Long Island Automobile Club.
April 17-24.....Montreal, St. Lawrence Hall, Fourth Annual Automobile Show, auspices of Automobile Club of Canada. R. M. Jaffray, Manager.

Races, Hill Climbs, Etc.

April 22-24.....Chattanooga, Tenn., Hill Climb on Lookout Mountain, Lookout Mountain Automobile Club.
April 24.....Philadelphia, Roadability Run to Atlantic City, Quaker City Motor Club.
April 26-May 1...New York City, Second Annual Automobile Carnival, New York Automobile Trade Association.
April 26.....New York City, Second Annual Hill Climb, Fort George-New York Automobile Trade Association.
April 28-30.....Pittsburg, Pa., Gazette Times-Chronicle Telegraph Three-Day Endurance Run. Indorsed by Automobile Dealers' Association.
April 30.....New York City, Endurance Run, New York Automobile Trade Association.
May 3-6.....Harrisburg, Pa., Third Annual Endurance Run, 700 miles, Washington, Baltimore, Scranton, Motor Club of Harrisburg.
May 10-13.....Detroit, Mich., Four-day Endurance Run, Detroit Automobile Dealers' Association.
May 18-19.....Norristown, Pa., Second Annual Endurance Run, Norristown Automobile Club, to Hagerstown, Md.
May 22.....Hartford, Conn., 200-Mile Endurance Run, Hartford Automobile Club.
May 22.....Newark, N. J., Third Annual Endurance Contest, New Jersey Automobile and Motor Club, 190 Miles.

July 4.....Los Angeles, Cal., Southern California Automobile Dealers' Association. Road Races, 250 Miles for Large Cars; 150 Miles for Light Cars.
July 7.....Detroit, Start of Sixth Annual A. A. A. Tour for Glidden Trophy.
Sept. 15.....Denver, Col., Start of Flag to Flag Endurance Run to Mexico City.
Oct. 7.....Philadelphia, Second Annual Stock Chassis, 200-Mile Race, Fairmount Park, Quaker City Motor Club.
Dec. 29-30.....Philadelphia, Fourth Annual Mid-Winter Endurance Contest, Quaker City Motor Club.

FOREIGN.

Races, Hill Climbs, Etc.

April 11-18.....Austria-Hungary, Prague, Automobile Exhibition Hill Climb at Koenigsaal, Automobile Club of Tcheque.
April 22-30.....France, Paris, Small Commercial Vehicle Competition.
April 26-May 13..Germany, Commercial Vehicle Competition, Kaiserlicher Automobile Club.
April 29.....Sicily, Voiturette Races.
May 2.....Sicily, Targa Fiorio, Automobile Club of Italy.
May 6-9.....Austria. Small Vehicle Competition, Automobile Club of Austria.

SPEARE AT A.A.A. HELM; HOTCHKISS ON NEW JOB

BOSTON, April 6.—Lewis R. Speare, the newly elected president of the American Automobile Association, to-night was tendered a dinner by the directors of the Bay State Automobile Association, the presidency of which he recently resigned because of his increased national duties. The function was made notable by the presence of the Massachusetts Highway Commission and well-known automobilits from various parts of the State, in addition to several from outside the State.

President Lewis R. Speare.

Of course, the recipient of the honor heard many pleasant things said about him, including reference to his unselfish activities extending over a long period of years and expressions of confidence in his ability to increase the power and influence of the national body.

In the enforced absence of President-elect Tudor, of the Bay State club, Secretary Fortescue made an efficient toastmaster. The oratorical fusillade was long and varied. The members of the highway commission, Chairman Harold Parker, Col. W. D. Sohier, J. H. Manning, and Secretary A. B. Fletcher, supplied timely talk, and ex-Congressman Thomas Powers of Newton contributed the real eulogy of the center figure of the feast.

The "also spoke" list included A. B. Bliss, president Massachusetts State Automobile Association; J. O. Heinze, preident Lowell Automobile Club; W. H. Chase, president Wachusett Automobile Club; J. P. Coghlin, president Worcester Automobile Club; S. L. Haynes, ex-president Automobile Club of Springfield; F. H. Elliott, secretary American Automobile Association; Charles J. Glidden, the globe girdler; J. C. White, secretary to the mayor of Boston, who was unavoidably absent; J. H. McAlman, president of the Boston Dealers' Association; E. A. Gilmore, president pro tem of the Boston Motor Club; A. G. Batchelder, and several others added to the hilarity of the occasion.

The dinner was held at the Hotel Carlton in the recently acquired clubrooms of the Bay State Automobile Association. Songs there were by an amateur quartette of rare excellence, and songs there were in which all present joined in the singing. Concisely summed up it might be said, as is often stated in the country weekly, that "a good time was had by those present."

REFUSES TO MAKE "JOY RIDING" A LARCENY.

ALBANY, N. Y., April 6.—Assemblyman Robinson secured unanimous consent to-day to the taking up and passing the bill to make it malicious injury to property and a misdemeanor to tamper with or injure a motor vehicle, which measure was similar to the one passed through the House Monday night. At the same time Senator Hill's bill to make it larceny to take an auto for a joy ride without the owner's knowledge or consent was received and referred to the Assembly committee on codes, having passed the Senate Monday night the same time that Assemblyman Robinson passed his anti-joy ride bill through the Assembly. The Assembly bill, however, only makes the crime malicious injury. This bill also contains the anti-tampering with an auto provision, and makes that a misdemeanor as malicious injury to property or interference therewith.

It is doubtful which of the bills gets to the Governor, as the Assembly codes committee would not stand for the bill making the joy ride larceny, and the Senate may amend the Robinson bill so as to make it larceny instead of malicious injury to property.

SURCHARGED with unselfish enthusiasm for a cause, and absolutely free from obligations that might prove embarrassing to his best efforts, William H. Hotchkiss, ex-president of the Automobile Club of Buffalo and ex-president of the New York State Automobile Association, on February 1, 1907, started out to make the American Automobile Association what the majority of its organizers intended it should be—the national body of automobilists of the country. Up to that time the A. A. A. had suffered a spasmodic existence, its demise having been imminent at several periods. But the national idea—first the local clubs, then the State organizations, and finally the whole cemented with a national board of directors and officers—survived because in the belief of the majority it was correct in principle and lived despite an emaciated treasury and leaders who made slow and indifferent progress with the poor tools at hand. There were only six State associations and about seven thousand members, with dues uncollected and requests for payment ignored.

Ex-President W. H. Hotchkiss.

Then it was that the man from Buffalo appeared on the scene, took up the work the others had thrown down, and soon made it evident that a real pilot had seized the helm of the A. A. A. ship, which no longer drifted, but set sail for a definite port. Of course, Hotchkiss antagonized some with his vigorous methods, but for every one lost he added a score to the growing army of automobilists, who were beginning to appreciate what its real work should be. Clubs were born and comatose ones revived by liberal quantities of the administrative juice, State work following as a natural sequence. National boards were formed with functions that were exercised, and while the machinery at first still creaked from its intermittent periods of disuse, the persistent application of lubrication soon had even the smallest cogs in consonant operation. Overseeing the job was the tireless disciple of Blackstone, whose energy often took him into a maze of details and made some of his lieutenants feel that either he should not waste his time in side channels or else their successors should be named.

This, however, was the nature of the man, for to insure success no detail was too small for his personal attention. Results, however, tell the complete story, and when the other week Judge Hotchkiss informed the A. A. A. directors that he could not serve out his third term, he relinquished the head of a national organization that had grown to 27 State bodies and over 21,000 members. Reluctantly the resignation was accepted, for it means the loss of a man who fought for the general good of automobiling and gave to it most generously of his time, which meant services that could not have been bought by any sum within the command of the association.

Called to the important and difficult place of superintendent of insurance of New York State, the Hotchkiss thoroughness and indefatigability will soon make itself manifest. Governor Hughes made no mistake in his selection.

Wheels are to be attached to an aeroplane which W. H. Martin, of Stark County, Ohio, has invented and built. These wheels will be 1 foot in diameter, and other changes have been made in the construction, the front rudder and the frame being altered before the plans for the next flight are arranged. Mr. Martin has been in correspondence with F. S. Lahm, of Paris, regarding engines.

Pathfinding Party of 1907 A. A. A. Tour.

"Phil" Flynn in center, next to him on left are Paul C. Wolff and Dal H. Lewis; on his right, Teddy Day (hatless) and Arthur Banker (leaning on mudguard of Pierce car).

DEATH OF PHILIP S. FLINN, OF PITTSBURG.

Philip Sheridan Flinn, of Pittsburg, Pa., a well-known automobilist, died in Atlantic City, Sunday, March 28, after a long illness, a result of acute stomach trouble, which affected his heart. Mr. Flinn had been especially prominent in automobile circles in connection with the annual Glidden tours. As a member of the touring board of the A. A. A., he took an active part in the pathfinding tour for the 1907 tour, and with his Pierce car made perfect scores in both the 1906 and 1907 tours. In the 1908 tour he did not enter, but he piloted the cars from a point north of Pittsburg to the last ridge of the Allegheny Mountains, east of Bedford Springs. Mr. Flinn was 44 years old.

DEATH OF PROMINENT QUAKER AUTOIST.

PHILADELPHIA, April 5.—Ferdinand M. Johnson, chairman of the contest committee of the Quaker City Motor Club, died this morning after but two days' illness. A slight cold, from which he had apparently recovered, developed into pneumonia. It is understood that Mr. Johnson's death will in no wise affect the schedule of events he had arranged for the coming season.

The dates for the endurance run to Pittsburg and return have been changed to June 14 to 18 inclusive, the former dates, May 11-15, being close on the heels of the Harrisburg run and but a few days previous to the Norristown run. The date for the 24-hour race has also been changed—from June 11-12 to June 25-26. The Orphans' Day run is scheduled for Wednesday, June 9. Entries for the road ability run to Atlantic City on April 24 are coming in rapidly.

DINNER TO DAVID BRUCE BROWN.

Thursday evening, April 1, the yacht room at the Hotel Astor, New York City, was the scene of a banquet, at which David Bruce Brown, the young amateur, who so successfully lowered records on the McIntosh 120-horsepower Benz at the recent Daytona meet, was the guest of honor. The dinner was given by the Benz Import Company, Manager Jesse Froelich acting as host. The guests included Hugh D. McIntosh, the well-known Australian sports promoter, and owner of the car which Brown drove; C. and Levi Weingarten, E. E. Maxwell, W. P. Buckley, Charles Scharfer, Jr., Willis B. Troy, Harry Fosdick, Fred. J. Wagner, C. B. Ames. E. E. Schwartzkopf, Baron William Gienauth, Wm. R. Kass, Ernest Stoecker, C. W. W. Donnelly, T. M. Simons, J. P. Muller, W. J. McBride, Duncan Curry, William Harrison and R. F. Kelsey.

Congratulatory speeches greeted Driver Brown, Manager Froelich and Owner McIntosh after the menu had been served, all of which were gracefully acknowledged by the trio in question. A life-size portrait of the German Kaiser adorned the wall back of the banquet table, and tiny German flags and American beauty roses formed the table decorations.

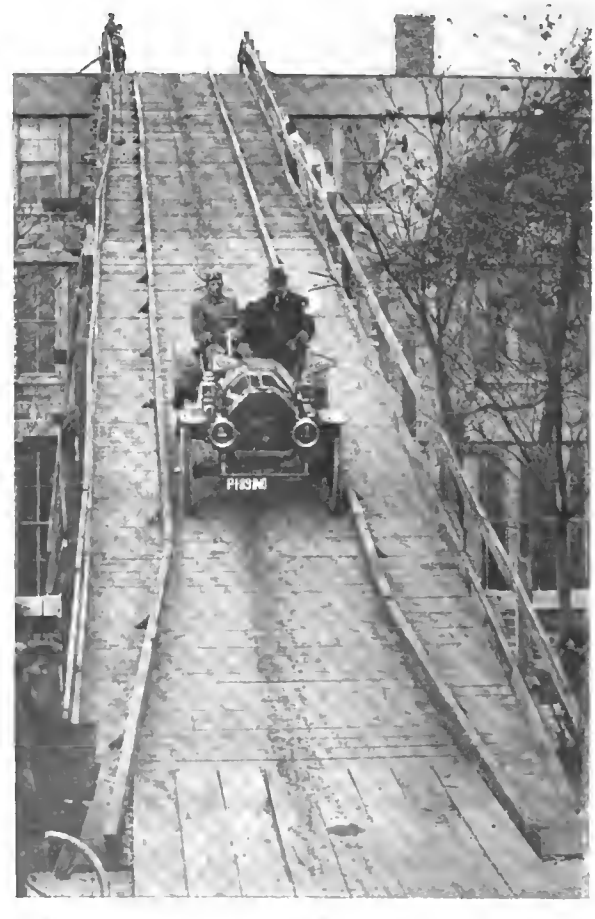
MRS. TAFT WILL DRIVE BAKER ELECTRIC.

WASHINGTON, D. C., April 5.—Mrs. William H. Taft, the "First Lady of the Land," has gone the President one better, for she will now operate her own car. She has recently placed an order for a Baker Queen Victoria electric with the Washington agent for the Baker Motor Vehicle Company, of Cleveland, and it will be delivered very shortly. The White House garage now has a White steam touring car and a Pierce gasoline limousine, so that the electric will complete the equipment of automobiles that has displaced the time-honored horse and carriage executive mansion oufits.

The car for Mrs. Taft will be the most elegantly appointed car ever built by the Baker company. It will be equipped with Exide batteries, handsomely upholstered in blue broadcloth; the coat of arms of the United States will be emblazoned on the door panels, and the interior will be noteworthy for its daintiness and refinement. That this decision of Mrs. Taft to drive her own machine will set a mark in the national capital is shown by the fact that since this was first known the Baker agents have had two requests for similar machines, one from the wife of an ambassador and one from the wife of a cabinet officer.

OVERLAND CLIMBS TO TOP OF GARAGE.

INDIANAPOLIS, IND., April 5.—Absence of hills, worthy of the name, in this vicinity makes it impossible for dealers to demonstrate the hill-climbing ability of cars which they handle. To obviate this difficulty, the Fisher Automobile Company has erected a structure from the side street to the roof of its garage, the length being 134 feet and the grade 39½ per cent. An Overland roadster made this climb in nine seconds flat, and this stunt was performed three times each day during the recent show week and always drew a crowd. The Fisher Company attributes many of the orders for 40 cars, which it took during the celebration, to this demonstration.



Overland Coming Down the Fisher Company's Artificial Hill.

Through Southern Florida in Premier "30s" with W. J. Bryan as Guest.

Michelin Starts the Racing Year Well.—At the recent speed carnival on the beach at Daytona, Fla., three new world's records were established on Michelin tires and two new world's records were secured last month at New Orleans during the Mardi Gras week contests. At Ormond David Bruce Brown won the DeWar Trophy, and established a new amateur world's record for one mile, and with the same car and Michelin equipment, he lowered the ten-mile world's record made by MacDonald on a Napier car away back in 1906. George Robertson, another Michelin enthusiast at Daytona, not to be outdone, wiped out the old five-mile records made by Lancia and Marriott in 1906 and established a new world's record for that distance. Other Michelin victories at Ormond include the one hundred mile contest for the Minneapolis Trophy; the two one hundred mile stock car events; the one mile invitation and the eight mile handicap. Michelins were again successful in all of the five laps of the interesting one hundred mile piston displacement contest, securing first, second and third place in every lap.

Immense Traffic at Franklin Factory.—As an index of industrial activity, figures are given showing the extent of the work of the traffic department of the H. H. Franklin Mfg. Co. at its automobile factory in Syracuse, N. Y. These figures show that for the past six months, constituting the first half of the present trade year, the shipments from the factory have aggregated 3,376,218 pounds. The shipments received include 2,399,477 pounds of merchandise, which with the addition of over 7,000,000 pound of coal, 1,000,000 pounds of lumber and several hundred thousand pounds of other commodities, makes a total of 11,367,675 pounds. In this period 342 freight cars loaded with Franklins have left the factory.

Times Square Automobile Company Enlarges.—The Times Square Automobile Company, of New York City, through its secretary, Jesse Froelich, has leased for a long-term of years the ground floor and basement of the property at 1591 to 1597 Broadway, at the northwest corner of Forty-eighth street. This will be added to the present quarters of the concern at 1599 and 1601 Broadway with an L to 215 and 217 West Forty-eighth street, giving it one of the largest establishments along the row. It is probable that the company will add several lines to those now conducted, chief of which will be the formation of a taxicab company, with a full line of cars.

Republic Rubber Company Opens Boston Branch.—Success in disposing of its tires in the territory around Boston, making it a principal distributing point, has obliged the Republic Rubber Company, of New York, to open its own office in that city. The branch will be located at 735 Boylston street, and a great deal of its trade will be in the staggard tread, which has proven popular there as well as in other large cities, where there are miles of smooth pavement.

Edison Company Uses an old Pierce Arrow.—After having been used continuously for five years by three different owners a 24-horsepower Pierce-Arrow has been placed in commission as a general utility car by the Edison Manufacturing Company of West Orange, N. J. The car is one manufactured in 1904. The only change made in the car was the removal of the tonneau and the substitution of a platform on which boxes and other material may be carried.

Morgan & Wright Enlarge Factory.—Building operations are now well under way at the factory of the Morgan & Wright Company, in Detroit, which when completed will increase the floor space of the plant by 20 per cent. The capacity of the factory has been taxed to fill orders, and last year it was run at night as well as day, so that additions became necessary.

Addition to Empire Tire Factory.—Empire Automobile Tire Company of Trenton, N. J., has decided to build an addition to its plant, because its trade has opened up so strongly that even by running at night as well as at day, it has been unable to care for its business.

Testing Track for Maxwell Factory.—The Maxwell-Briscoe Motor Company is having a half-mile testing track constructed at its Newcastle, Ind., factory, built of crushed stone, forty feet wide, and with curves well banked. It will cost about $3,000.

Auto Factory for Council Bluffs, Ia.—The Nevada Motor Car Company has purchased the property at Washington avenue and Main street, Council Bluffs, and will shortly commence the erection of an automobile factory, to produce drays and trucks.

Camden Reduces Speed Limit.—Camden, N. J., has had its little say, and has reduced the speed limit of automobiles to eight miles an hour, and including motorcycles in the same category. The limit was formerly very reasonable—12 miles per hour.

Fisk Company Issues Comic Posters.—The Fisk Rubber Company has issued a set of comic posters in colors, which it has sent by request to a number of automobile clubs throughout the country, attractively framed.

IN AND ABOUT THE AGENCIES.

Crawford, Philadelphia.—The Philadelphia agency for the Crawford, which until a week ago was represented in that city by the Thomas M. Twining Company, has been taken over by the Crawford Automobile Company, of Philadelphia, with headquarters at Broad and Ridge avenue.

Velie: Minneapolis, Minn.—Mich Auto Company, for local trade; Deere-Webber Company continuing with wholesale trade.

Winton and Sterling: Des Moines, Ia.—Strong Motor Car Company, 917-19 West Grand avenue.

Fritchie: Los Angeles, Cal.—Electrical Construction Company, for southern California.

Brush: Freehold, N. J.—Frank Du Bois, for the western half of Monmouth County.

Anderson, Utica, N. Y.—Bailey & Bowne, Whitesboro and Wiley streets.

Oakland: Cleveland, O.—Avenue Motor Car Company, 1806 Euclid avenue.

Matheson: Newark, N. J.—Motor Car Company of New Jersey.

Velie: Los Angeles, Cal.—Standard Motor Car Company.

Matheson: Detroit.—J. P. Schneider, State agent.

American: Trenton, N. J.—Chauncey Van Horn.

Rambler: Opelika, Ala.—Walter Greene.

Moon: New Orleans, La.—E. F. Martin.

Roe: Opelika, Ala.—C. M. Cannon.

PERSONAL TRADE MENTION.

E. Percy Noel, advertising manager of the Moon Motor Car Company, of St. Louis, in addition to writing on technical and aeronautical subjects, is also engaged in lecturing on these subjects. He has spoken on "Locomotives of the Air" before the railroad men's branch of the St. Louis Y. M. C. A., and at the central branch on "Air Travel of To-day," both illustrated.

Willie Haupt, the young Philadelphian who was so successful in hill climbs and races last season with a Great Chadwick Six, has severed his connection with

An Up-to-date Albany Salesroom.

C. S. Ransom is the distributor for the Stevens-Duryea, Lozier and Chalmers-Detroit cars at Albany, N. Y., and has a fine location at 81 Chapel street, opposite the Hotel Ten Eyck. The dimensions, 30x75 feet, afford ample space for offices, a stock of automobile supplies and quite a number of cars.

the Chadwick Engineering Company, and while at present temporarily engaged, is looking for a high-speed car, with which to enter events this year.

Godfrey G. Luthy, secretary of the Bartholomew Company, of Peoria, Ill., the manufacturers of the Glide cars, is receiving the congratulations of his many friends upon the announcement of his approaching marriage to Miss Elizabeth A. Radley, which will occur in that city, April 20.

Ernest L. Ferguson, of New York City, has been elected secretary of the Contest Board of the A. A. A. Dai H. Lewis, who has been secretary has resigned to give all of his attention to his duties as secretary of the Automobile Club of Buffalo.

W. L. Walls, who has been acting manager of the Kansas City branch of the Studebaker Company, has severed his connection with that concern, and has taken a position as manager of the Maxwell-Briscoe Company's branch in St. Louis.

H. E. Rocklege has resigned from his position as manager of the Missouri Valley Automobile Company of Kansas City, Mo., and in the future will act as traveling representative of the Maxwell-Briscoe Automobile Company, of that city.

R. W. Harroun, the inventor of the Harroun bumper, is now associated with the Factory Sales Corporation of Chicago, in a selling capacity.

OBITUARY.

Jacob Neuman.—Jacob Neuman, vice-president and general manager of the Stein Double Cushion Tire Company of Akron, O., died on March 27.

TAXICAB AND TRANSIT.

Detroit, Mich.—The newly incorporated Taxicab Service Company has arranged to use Chalmers-Detroit cabs in its service, and all will have yellow hoods as distinguishing marks. The following officers have been elected: President, T. W. Henderson; vice-president, H. G. Lyle; treasurer, Geo. King; secretary and general manager, L. S. McCreery.

Frederick, Md.—Interests in Frederick, Md., are back of an enterprise to establish an automobile stage line between that city and Emmitsburg, 22 miles distant. Fast machines to Harmony Grove, Hansonville and Mount St. Mary's College will be running by May.

RECENT INCORPORATIONS.

Kissel Motor Car Company, New York.—Capital $50,000. To manufacture horseless vehicles, motors, engines, carriages and wagons. Incorporators: F. S. Waldo, Andrew Kirkpatrick, J. G. Fitzgerald, 214 West 80th street, New York City.

William Stevenson Garage Compsny, Morristown, N. J.—Capital $50,000. To manufacture, repair, etc., automobiles, etc., general automobile garage business. Incorporators: William Stevenson, Annie C. Stevenson, W. W. Crane.

Armstrong Buggycar Company, Atlanta, Ga.—Capital $25,000. To buy and sell buggy-cars and automobiles and other vehicles, and to maintain garages. Incorporators: R. K. King, D. D. Armstrong, Thos. Scrutchin.

Originator Mfg. Company, Jersey City.—Capital, $125,000. To build automobiles and do a general merchandise business. Incorporators: V. J. Mills, New York; J. C. Inwright and B. L. Inwright, Jersey City.

Phoenix Auto & Raincoat Company, New York.—Capital $10,000. To manufacture auto and rain coats and female wearing apparel. Incorporators: Jacob and Norman Lederer and Herman Rosenberg.

American Mors Company of Illinois, Chicago.—Capital $25,000. To manufacture and deal in automobiles and other motor vehicles. Incorporators: E. W. Pottle, Rudolph Goefert, G. J. Meier.

Roy A. Faye Company, Boston.—Capital $50,000. To do a general automobile business. President, R. A. Faye; treasurer and clerk, F. D. Bennett.

Motor League of America, Syracuse, N. Y.—Capital $100,000. To manufacture motors, engines, cars and vehicles. Incorporators: A. A. Schlachter, Ernest Woods, T. A. Levy.

Pittsburg Auto Delivery Company, Camden, N. J.—Capital $125,000. To carry on an automobile delivery business. Incorporators: W. A. Pittis, A. Wood, V. A. Murray.

Pittsburg Auto Delivery Company, Pittsburg.—Capital $125,000. To construct vehicles of every kind. Incorporators: W. A. Petters, A. Wood, V. A. Murray.

Griswold Garage and Machine Co., Port Jefferson, N. Y.—Capital, $20,000. Incorporators: F. C. Griswold, L. H. Chambers, F. C. Dildene, J. B. Overton.

Aero Club of Dayton, Ohio.—Incorporators: G. W. Shroyer, Dr. L. E. Custer, G. R. Wells, F. C. Carter, P. M. Crume, William Dennick.

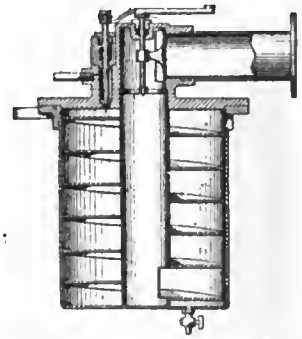
Mitchell Motor Car Company, Racine, Wis., has filed an amendment increasing its capital stock from $500,000 to $1,000,000.

SELECTED AUTO PATENTS.

Issue of March 30.

916,465. Carbureter.—Ralph L. Looby, New York City. Filed Sept. 9, 1908.

This device has an entirely new method of vaporizing the fuel, which consists of allowing it to flow down a spiral passage through which the air flows, but in the opposite or upward direction. The spiral passage surrounds a central chamber in which may be hot air, thus assisting in vaporization. The throttle valve which controls the outflow of gas is at the top, as is also the gasoline inlet. This arrangement makes the whole device exceedingly simple.



Section Looby Carbureter.

916,491. Rotary Engine Valve.—Joseph Rothschild, Bayonne, N. J. Filed Feb. 18, 1908.

916,529. Attachment for Vehicles.—Edwin F. Brown, Chicago. Filed May 6, 1907.

916,678. Automobile Tire.—Bruno R. G. Darre, New York City. Filed Nov. 9, 1908.

916,694. Spark Timer.—Herman W. Gabel, Fond du Lac, Wis. Filed Oct. 14, 1907.

916,784. Vehicle Tire.—Barton Ross, Buffalo, N. Y. Filed Sept. 24, 1907.

916,871. Spark Plug.—Gabriel P. B. Hoyt, New York City. Filed March 25, 1908.

916,888. Axle for Motor Road Vehicles.—Louis Renault, Billancourt, France. Filed Dec. 12, 1906.

Farmer Goepfert in His Rambler Inspecting Corn Bins.

At Abilene, Kan., W. H. Goepfert owns one of the largest corn farms in the State. He uses a Rambler in all his trips about the place. In the background 1,200 bushels of corn are shown in the cribs.

INFORMATION FOR AUTO USERS

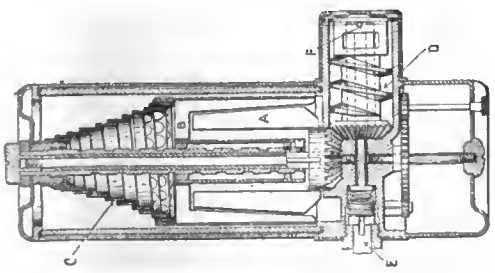
A Handy Tire Repair Kit.—A very complete and compact repair kit, suitable for repairing all makes and types of automobile tires, is manufactured and sold by the Michelin Tire Company, Milltown, N. J. This outfit, which is shown in the illustration, includes one elbow lever, one spur lever, one tube of talc, one roll of friction fabric, two tubes of Michelin patching cement in a metal

MICHELIN TIRE REPAIR KIT.

box, four red rubber patches of different sizes with beveled edges and one dummy valve. These various components are contained in a substantial and well finished wooden box with sliding cover. Several of the articles mentioned are worthy of special mention, including the Michelin elbow and spur levers, which greatly reduce the labor involved in putting in place or removing clincher tires of all types. These tools are very strong, well finished, and form a useful addition to any repair kit. The illustrated instructions that accompany the Michelin outfit show clearly the various operations in which these tools are used.

Michelin patching cement, two tubes of which are contained in this repair kit, is made of pure unadulterated dissolved Para rubber. It is one of the strongest and most satisfactory cements on the market and may be purchased in larger quantities in both tubes and cans of various sizes for private use and for garages and repair stations.

Casgrain Speedometer.—This instrument employs for its principle one of the oldest-known forces—liquid motion. A certain quantity of liquid is confined within a cylinder with absolutely no chance of escape, as the shaft connections are made above the level of the



SECTION VIEW CASGRAIN SPEEDOMETER.

liquid; and as a further precaution, the gear marked C in the sectional illustration shown, is fitted with a worm, which when revolved excludes all oil from the tubular projection, within which the only outlet is enclosed. Thus a certain amount of oil confined within a certain space, is rotated by paddles marked A, at a certain speed, thus setting up a liquid motion in suitable proportion to the speed at which paddles marked A are revolved. This current in turn, sets up a drag on paddles marked B, to which indicating dial is fixed, and it is this drag which causes indicating dial to be rotated on a spiral shaft, marked C, against a compensating spring in suitable proportion to speed at which paddles A are rotated.

By the above means the large individual figure is shown at the indicating point for every consecutive mile on the scale. The scale is 28 inches long, passing four and one-half times round a cylinder of 2⅛ inches diameter. The absence of any mechanical connection between the driving mechanism and the indicating dial, is, with the view of eliminating inaccuracy that may be caused from wear, and absolute steadiness is claimed because the liquid absorbs the vibration. Each figure on the dial is placed by hand according to individual electrical test, each figure being put in its proper location regardless of its position in relation to another. The Casgrain speedometer is manufactured by the Couch & Seeley Company, 10 Thacher street, Boston.

Bowser Direct Lift Garage Storage.—Gasoline has to be safely housed, and for convenience in drawing supplies from time to time, S. F. Bowser & Company (Inc.), of Fort Wayne, Ind., offer what is catalogued as the "direct-lift" system, which, however, is but one of the many Bowser plans, all of which are fully described in Bowser literature. In the direct-lift system the gasoline is stored in a steel tank under the ground and the pump is placed directly over the storage tank, thus making a low-priced, safe system for the storage of automobile gasoline. In these days when the quality of gasoline is none too good, it is necessary to conserve what is left of quality in it, and it can be done if the gasoline is removed from the package and stored in steel tanks built for the purpose.

A New and Popular Igniter.—The American Igniter, manufactured by the American Electric Fuse Company, Muskegon, Mich., is a combination of timer, coil and distributer enclosed in a single case, dust, heat and moisture proof, and so designed that it can be mounted directly on the cam or timer shaft, thus freeing the dashboard of the coil boxes and vibrators. The coil is a large and powerful one, and is non-vibrating. It is designed to operate any number of cylinders, and has a large winding area. Its makers assert that they have been able to nicely determine in its construction the proper proportion between the primary and secondary coils, thus securing the maximum efficiency with the minimum of current consumption, and an exceptionally hot spark on 2-5 amperes of current is the result. But one adjustment is required to regulate the spark for any number of cylinders. Although this igniter has been on the market for a short time, the makers have found it necessary within the last month to order approximately $10,000 worth of new machinery to care for the rapidly growing business. As will be seen, the American Igniter is a complete ignition system. The makers guarantee it to be satisfactory in every respect.

Reflex Spark Plugs.—Several new ideas in design are embodied in the spark plugs being made by the Reflex Ignition Company of Cleveland, principally dealing with the core and insulation. The plugs are of the condenser type, the steel electrode and baffle plate being machined integral, and the tip is made of an alloy which will not oxidize or warp. The insulation is double, the inner section being rolled lengthwise on the core from a thin strip of pure mica. The outer sections are simply mica washers, to act as a protection to the inner insulation, and there is no packing required, for the core is held in position by bronze seats. The nose has two ports for escaping gases, and a baffle plate, which is a new feature, inasmuch as it is claimed to keep the oil from reaching the insulation. The shell is machined from cold-rolled steel and tempered, the spark gap having a specially machined beveled rim. The plugs are made in standard, metric, A. L. A. M. and half-inch threads, and interchangeable porcelains can be furnished.

REFLEX SPARK PLUG.

Tungsten Lamps Used.—The new tungsten lamp, in which life, efficiency, and rugged service are as pronounced features, made it possible to consider electric lighting in cars as a permanent thing. Black Manufacturing Company, of Fort Wayne, Ind., taking advantage of the utility of the tungsten lamp and with a fine display of inventive faculty, completed a system of lighting for automobiles, in which the company's very efficient battery plays an important part. Then, the new "Parabolic" reflector, as here illustrated, has much to do with the success of the Black system. The company reports this system of lighting as in brisk demand.

THE AUTOMOBILE

Laying Out the Route for the Glidden Tour

By Len G. Shaw

Pathfinding Party of the A. A. A. Annual Tour Before Leaving Detroit on Its Arduous Spring Journey.

DETROIT, April 12.—With great éclat the E-M-F "30" car that will act as pathfinder for the Glidden tour pulled away from the Hotel Pontchartrain this morning and started on the six weeks' grueling trip which will take it to Chicago, Minneapolis, Omaha, Denver and back to Kansas City, where next Summer's journey and contest for the Glidden Trophy will end.

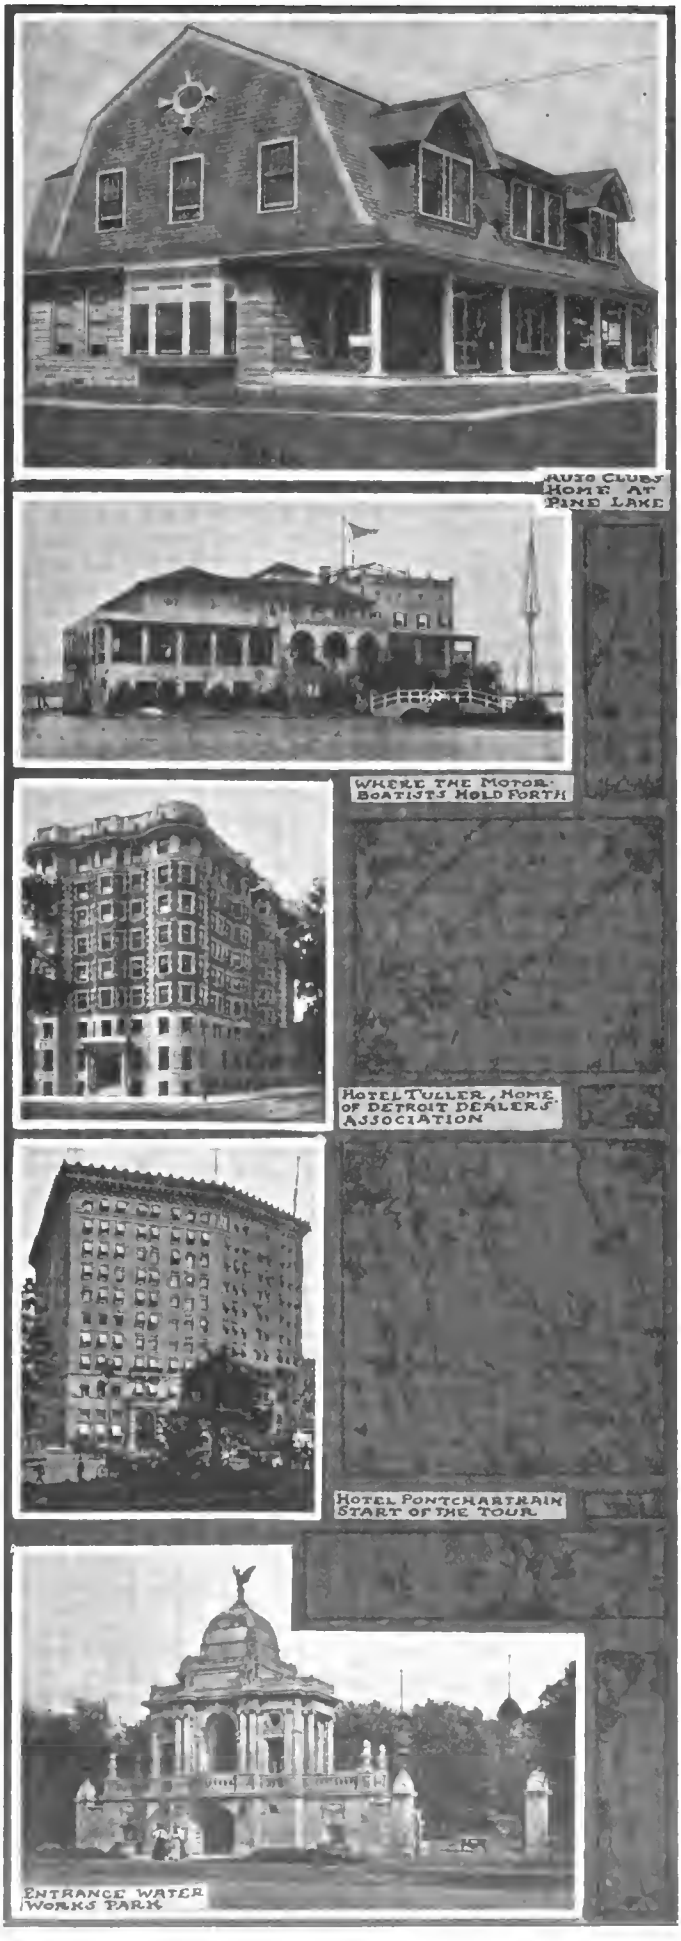
It was a fitting send-off that the car and its occupants received. Members of the Detroit Automobile Dealers' Association, to whose efforts was largely due the securing of the A. A. A. tour start from this point, and a great number of motoring enthusiasts were on hand to wish the tourists good luck and accompany them out of town. The Pontchartrain was thronged with curious mortals for hours before the time set for the start, and the pathfinding car, stationed in Cadillac square, adjoining the hotel, was the center of attraction for a crowd that at times seriously interfered with traffic. It was a good-natured assemblage, and when at last the "pathfinder" and consorts started off on the first stage of the trip a mighty cheer went up.

Detroit Possesses Beauty.

Secretary Dai H. Lewis, whose fondness for the feathers once he has reached them is proverbial, but who can check his slumber before the alarm clock has finished its get-up song, broke his record by getting up bright and early. Lazarnick, the snap-shotter, too busy elsewhere, sent his associate, Kron, who will cover the trip. The party got away in good season, the sun coming out from under the clouds long enough to bid adieu, with a 40-mile "zephyr" from the South giving assurance of plenty of fresh air on the opening day, at least.

It is worthy of note that the E-M-F "30" which will carry the pathfinders through to their destination and then make its way back to Detroit came out of the finishing room at the factory at just noon on Saturday last, with never a taste of the road up to that time. Whisked off the elevator, the commutator was given a slight adjustment, and George Meinzinger, the driver, who will take the car through, E. Leroy Pelletier, the advertising manager, and one or two others climbed in and gave the car its first touch of the strenuous life. A run of a few miles, and it went back to the factory to have tire cases, luggage holders, and other appliances fitted, and was ready to start that afternoon, if needs be. No special preparation was made, a stock car taken from the regular factory run being selected, showing the thoroughness with which the E-M-F product is made. President Lane of the D. A. D. A. handed a flag to Lewis to present to the Denver Automobile Club. "Tell them we will come and get it in July," said Lane.

Pelletier Entertains Lewis.



Of course, Dai H. Lewis, secretary of the Contest Board, will make the entire journey in the car, as will the driver, Meinzinger, no mechanician being carried. Mr. Pelletier will go the greater portion of the way. In addition a member of the local press will be picked up at each important point, continuing with the party until the next man relieves him. This gives variety, and at the same time stimulates local interest.

Six Weeks Required to Lay Out Tour.

Pathfinding, as the initiated know, is no sinecure. The distances must be carefully computed, every distinguishing mark along the route noted, every turn or cross-roads photographed, and an astounding amount of detail looked after. On the six weeks which will be occupied by the pathfinders it is expected that not less than one thousand photographs will be taken. No attempt at breaking records will be made, owing to the exacting nature of the work. The journey will be made by easy stages, as easy stages go at this season of the year. The trip is undertaken fifteen days earlier this year, but no difficulty is anticipated.

Preliminary to the start, a dinner was tendered officials of the Detroit Automobile Dealers' Association, members of the local press and few others at the Hotel Portchartrain, Sunday evening, Dai H. Lewis being the guest of honor and E. Leroy Pelletier acting as host. In the course of his talk Secretary Lewis stated that to date 29 entries had been received, as against six at this time last year, and he fully expected that by the closing date the number would total one hundred.

Now Possible for an Individual to Win Glidden.

This year, for the first time, it will be possible for an individual entrant to win the Glidden trophy. It will not be a competition between clubs, and there will be no teams. The winner of the Glidden prize will have personal custody of it for a year, it being a perpetual trophy. There will be a new Hower trophy for runabouts, which will become the permanent possession of the winner as in former seasons. This year there is also a new prize for cars with miniature bodies, or double rumbles. This is known as the Detroit trophy, it having been subscribed for and presented by the motorists of that city. The Glidden deed of gift had to be altered to permit of its going to an individual instead of a club, and the rules of the contest have been modified accordingly, the changes being such that a single winner is certain to be evolved. The cars will be classified and penalties will be imposed in fractions of a point for repairs and replacements.

The tour will be a little longer than usual this year, but not much more strenuous, except that the rules will be more exacting to prevent the large number of tied scores there have been at the finish in former yeras. Some poor roads will be encountered west of Chicago, but Glidden contestants will not be surprised at anything in this line and it is expected that the average daily distance covered will be as great or greater than in former years.

The most distinctly novel feature of the tour this year will be the arrangements for the overnight accommodation of the contestants over a part of the distance west of Chicago. Arrangements are being made to have a group of sleeping and dining cars accompany the tour and be sidetracked at the various night stopping places. This is necessary because of inadequate hotel room. It will obviate the annual bickering about "a room and bath" in places where there are not enough for all, and also it will make it compulsory to exclude women from the tour. The cars will afford accommodations at a lower cost than hotels.

What Happened the First Day's Journey.

JACKSON, MICH., April 12.—The first day's grind of the Glidden pathfinder came to a close late this afternoon, Jackson being the stopping point for the night. No attempt at making time marked the journey, but the 75 miles were covered in six hours, including a stop of one hour at Ann Arbor for dinner and numerous halts along the line while Secretary Lewis and Photographer Kron secured data and pictures for the use of the tourists next July. This day's run would not be worth chronicling were it not for its value in showing what can be accomplished over southern

Michigan roads. A 30-mile head-on wind blew all day, at times assuming the proportions of a gale.

But when it was all over to-night Secretary Lewis was jubilant. "Fine roads, as good as I ever encountered, particularly at this time of the year," said the veteran pathfinder. "When you can make a run like that in the middle of April, there is no limit to what you can accomplish in the middle of July."

Pathfinder Encounters an April Snowstorm.

KALAMAZOO, MICH., April 13.—The pathfinder had a most strenuous day, forcing its way through a blinding snowstorm during the greater part of the forenoon. The party reached here this afternoon, after navigating roads that were miniature lakes. South Bend is the destination of Wednesday night.

ABOUT THE CITY OF THE STRAITS.

DETROIT, April 12.—Brief though their stay may be, Glidden tourists who foregather in Detroit in July, making this the starting point of the year's big event in motordom, will long have reason to remember with pleasure their visit here. Every waking hour—and the others will be few—will be monopolized by the local entertainment committee, and from the time the vanguard arrives until the last tourist has left the city, there will not be a dull moment.

Those whose interest centers in the motor industry will find more here that is worth while than in any other city in the world. Detroit is admittedly the hub of the automobile industry, being among the first to produce practical cars, and leading the procession from that day to the present time. It has ten of the largest factories devoted to the manufacture of motor cars ranging in price from a few hundred dollars up as high as the purchaser may desire to go, and a score of smaller plants. This season they will produce all told in excess of 50,000 cars—not press agent, but real ones—all of which will be sold for real money. These cars will have a market value of considerably more than $55,000,000. If placed end to end they would make a string more than eighty-five miles in length, and would be able to transport an army of 200,000 men at one time.

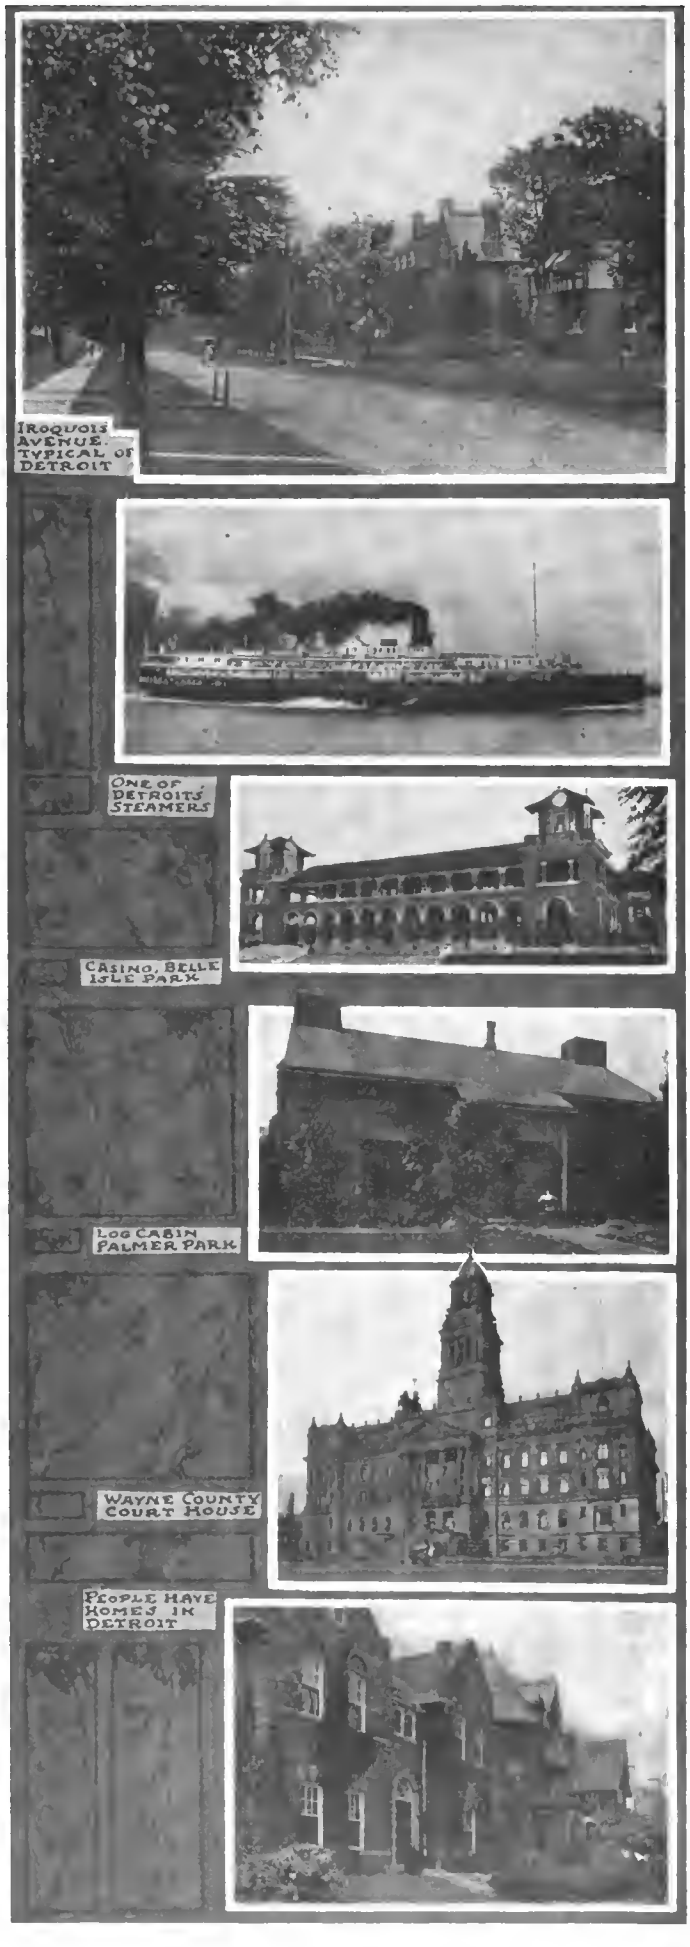
Will Have Entree of the Big Auto Plants.

The Gliddenites and others who gather here at that time will be given entrée to all these factories, affording them an insight into the magnitude of the industry and what the production of a high-grade automobile involves that they have hitherto lacked.

Motor enthusiasts will find at the Packard Motor Car Company's plant the most complete institution of its kind in America, if not in the world. A stockholder once facetiously remarked that just as often as they got a few dollars ahead orders were placed for a fresh supply of building materials and began an addition to the factory. This isn't quite true; if it was they would be building all the time. However, not a year passes without extensive additions to the plant that, even to the experienced, seems sufficient for all time to come, and which now embraces something like eighteen acres of floor space. It isn't that the Packard Company produces so many cars. It's output this season will be around the 2,000 mark. But—"ask the man who owns one"—it is the infinite care expended on every detail, and the fact that the car in its entirety is made under the Packard roof, that requires such facilities.

The Cadillac Motor Car Company is another concern that manufactures automobiles instead of making them, a distinction too often overlooked. The Cadillac plant is one of the wonders of the automobile world, and it will turn out some 9,000 cars.

There is the Ford Motor Company, pioneer in the low-priced medium-power field, and one of the largest producers of automobiles in the country. Just now every energy is being bent toward getting into its fine new plant at Highland Park, a suburb of Detroit, but in spite of the handicap of attempting to run two places at one and the same time the Ford Company will this season turn out something like 20,000 cars.



The E-M-F, which since its organization, less than a year ago, has kept the trade guessing, and which will this season put on the market, and sell, some 8,000 of the popular "E-M-F 30" cars; the Chalmers-Detroit, with one of the best equipped plants imaginable and an output in excess of 3,000 cars; the Blomstrom Gyroscope, the Regal, Brush Runabout, and Hereshoff, one of the most recent additions to the local colony, but which has already achieved pronounced success; the De Luxe, and nearly a score of lesser lights, are numbered among the concerns that are making Detroit famous and providing the country with automobiles. One can obtain luxury or practice economy.

Detroit Has Many Notable Attractions.

But it will not be necessary for Gliddenites to confine their attentions to automobiles, nor is it the intention of those in charge of the arrangements that they shall. Detroit has no peer in the matter of attractions. If there were nothing else, the Detroit River has given the city world-wide fame as a summer resort. Forming as it does the connecting link between the upper and lower Great Lakes, it provides a marine pageant the like of which cannot be found elsewhere. Here during the months when navigation is possible, giant freight steamers carrying trainload after trainload of iron ore destined for the furnaces of Ohio and Pennsylvania and grain for Eastern and European mills, or bearing coal and general merchandise for the thriving cities and farming communities of the Northwest, pass Detroit on an average of 10 minutes apart, day and night.

Belle Isle, situated in the Detroit River at the eastern end of the city, is the finest natural park in America. From the shady driveways or the broad verandas of the Casino there is afforded an unobstructed view of the passing fleets, with Detroit, half hidden in the smoke from its multitudinous factories, stretching for miles along the river, while in the opposite direction are the broad waters of Lake St. Clair, with the Canadian shore, dotted by summer homes, in the distance. Nature dealt leniently with Belle Isle, and a thoughtful municipality has supplemented its efforts in providing a beauty spot that outranks all others in the city where life is worth living.

There is practically no limit to the charming rides that can be taken in the vicinity of Detroit. Grosse Pointe, with its miles of macadam roadway, with Lake St. Clair on one side and "Millionaires' Row," the summer homes of Detroit's kings of finance, on the other, with the magnificent Country Club and golf courses, is one of the most popular points. You can motor out through Oakland County, up hill and down dale, in among the scores of little lakes that dot the district, or take a run to the home of the Detroit Auto Club, at Pine Lake, where every courtesy will be extended the Gliddenites. For a nominal sum the motorist who so desires can "go abroad," crossing the river, and upon the execution of a bond and the payment of a small license fee being permitted to spin—not speed, for such things are not tolerated across the border—along the "king's highways" in Canada.

Forsaking the auto for even a few hours, it is possible to board a palatial steamer and for an insignificant sum enjoy a cruise through the St. Clair Flats, the Venice of America, or, traveling in the other direction, witness from the deck of the steamer a marine parade that has no equal, passing on the way to Bois Blanc Island and other down-river resorts, the Hellgate of the Great Lakes, the Limekiln Crossing, upon which the United States government has spent upward of $6,000,000, and where the greatest engineering undertaking of its kind in the world is now in progress, involving the expenditure of another $6,000,000 in cutting in the dry a channel through miles of rock.

Headquarters for the Gliddenites will be at the Hotel Pontchartrain, but they will also be given full sway at the Hotel Tuller, home of the Detroit Auto Dealers' Association, and the other hostelries with which Detroit is so liberally provided. Arrangements for the entertainment of the visitors are proceeding apace, it being the determination of the D. A. D. A., the Board of Commerce, the local auto manufacturers and others to make the occasion a memorable one.

Fifth Avenue, New York, on Easter Sunday Illustrated the General Use of Motor-Driven Vehicles.

EIGHT CLASSES ARE PROVIDED FOR BY M. C. A. RULES

EIGHT classes have been provided for by the rules committee of the Manufacturers' Contest Association, and five of these are according to piston displacements with minimum weight limits. The results were first the work of the special rules committee, selected from the general committee of twenty-five, and these were the men who struggled with the knotty problems: H. E. Coffin, Chalmers-Detroit Motor Car Company, chairman; A. L. Riker, Locomobile Company of America; George A. Weidely, Premier Motor Manufacturing Company; F. B. Stearns, The F. B. Stearns Company; Edgar Apperson, Apperson Brothers Automobile Company, and Paul LaCroix, Renault Freres Selling Branch.

The result of their work was then referred to the committee of twenty-five, which now officially announces through Secretary Russell A. Field what has been recommended to the contest board of the American Automobile Association, the adoption of which is foreshadowed in advance. The price classification of the American Automobile Association was readoptcd, with the stipulation that it apply to stock car events, making the complete classifications recommended for 1909 as follows:

Piston Displacement In Cubic Inches.	Min. Wght. in Lbs.	Class.	Price.
.....	....	8	Special
.....	....	7	Open
.....	....	6	$ 850 and under
160 and under	1,200	5	851 to $1,250
161 to 230	1,500	4	1,251 to 2,000
231 to 300	1,800	3	2,001 to 3,000
301 to 450	2,100	2	3,001 to 4,000
451 to 600	2,400	1	4,001 and over

Other changes were recommended, including the designation of a stock car, the new rule for which will read as follows:

STOCK CAR.—A motor car completely described in the manufacturer's catalogue for the current or any preceding year, which is manufactured in quantities of 25 or more, which is on sale by the regular selling representatives of the manufacturer and is manufactured ready for delivery to buyers. Top, wind shields, and extra tires may be removed. The muffler cut-out is optional.

In reference to stock chassis, the present clause reads:

STOCK CHASSIS.—A chassis, which without any changes whatsoever, except that lighter read springs may be used, can, by adding the necessary parts, be assembled into a complete stock car for which it is designed.

To it was added the following:

Vehicles for stock chassis races must be the product of a factory which has, during the twelve months prior to the date of the event, produced at least fifty (50) motor cars regardless of model. The A. A. A. minimum weight clause, with an allowance of 2 per cent., will govern. It is further provided that additions to the oil and fuel supplies, a change of steering gear angle of driving gear ratio and of tire and rim equipment are left optional with the entrant.

It was unanimously voted to recommend to the Chicago Automobile Club that its race for the Cobe Cup and the small car event to preccde it both be for stock chassis and held under piston displacement classifications.

In the final adoption of the classes nearly every member of the general rulcs committee took part in the discussion. There were present at the meeting: Edgar Apperson, Apperson Bros. Automobile Company; A. P. Brush, Buick Motor Company; H. E. Coffin (chairman), Chalmers-Detroit Motor Company; C. H. Tangeman, Hol-Tan Company; C. M. Hamilton, Isotta Import Company; H. G. Farr, Knox Automobile Company; A. L. Riker, Locomobile Company of America; H. A. Lozier, Jr., and C. A. Emise, Lozier Motor Company; Benjamin Briscoe, Maxwell-Briscoe Motor Company; Alfred Reeves (proxy), Mitchell Motor Car Company and National Motor Vehicle Company; R. H. Croninger, Pennsylvania Auto Motor Company; E. P. Chalfant (proxy), Pierce-Arrow Motor Car Company; G. A. Weidely, Premier Motor Manufacturing Company; Paul Lacroix, Renault Freres Selling Branch; F. B. Stearns, The F. B. Stearns Company; F. A. Barker, Dayton Motor Car Company; Walter White, The White Company; E. Lillie, Itala Import Company.

CHICAGO'S TWO ROAD RACES ARE DEFINITELY ANNOUNCED

CHICAGO, April 12.—The sanction for the road racing carnival of the Chicago Automobile Club, June 18 and 19, has been granted by Chairman Hower, of the A. A. A. contest board, the local promoters having complied with all requests as to military protection, permission to use the course, and the financing of the events. In addition to this the A. A. A. chairman has permitted the Chicago club to modify the classifications of the Manufacturers' Contest Association because of the fact the new rules were designed mostly for 1910, while the Chicago events were outlined before the birth of the new organization.

Under this special dispensation the contesting cars for the Cobe trophy will be limited to a piston displacement of 525 cubic inches, while the weight limit has been reduced from 2,400 to 2,150 pounds.

The club has accepted the classification of the M. C. A. for the other event, which will be for light cars instead of being a "baby" race such as was run at Savannah. In this the piston displacement limit will be 300 inches, while in the way of a concession the weight limit has been knocked off entirely.

Probably the greatest triumph achieved by the Chicago Automobile Club is the securing of troops to guard the course, something unheard of heretofore outside of Georgia. The most remarkable part of it, though, is that permission has been given to take Illinois soldiers into Indiana for this purpose, the First Regiment of the Illinois National Guard having been secured for police duty. A camp for the troops will be established near the starting point, which will be on the east leg of the course about a mile and a half from Crown Point. The signal corps of the regiment will run a military wire round the course, and the hospital corps will be on duty with all its paraphernalia, for ready duty.

Entry blanks for the two road races will be out this week, and of course no time will be lost in placing them in the hands of the manufacturers, most of whom seem eager to give the race strong support. The fees have been placed at $500 for the first car, $300 for the second, and $200 for the third, both races to count in the total number. The classifications for the two races are as follows:

Cobe Trophy Race, June 19.—Open to stock chassis of 1909 models or earlier, of which ten have been built, and 1910 models, of which the parts for ten are on hand at the factory of entrant prior to June 1, 1909, manufacture of same to have commenced. The entrant is to furnish affidavit proving the eligibility of the entry under above conditions, and is to furnish a bond of $5,000, made payable to the treasurer of the A.A.A., which bond is to be forfeited to the A.A.A. in the event of the entrant failing to construct ten cars according to his affidavit, said cars to be completed on or before October 1, 1909. This race will be approximately 410 miles in length, cover a 24-mile circuit over the public highway. Minimum weight of chassis, with tanks empty, 2,250 pounds; maximum piston displacement, 525 cubic inches in the whole engine.

Light Car Race, June 18.—Open to stock chassis under same conditions as the Cobe trophy race as to number of models built, etc., but not to have over a maximum piston displacement of 300 cubic inches in the whole engine. No weight limits imposed.

Optional Construction.—All must be stock except: Extra gasoline and oil capacity, no change in principle; any angle of steering column and gear; any gear ratio of driving system; any tire and rim equipment.

CONTESTS OF THE CHICAGO MOTOR CLUB.

CHICAGO, April 22.—An endurance run for cars listing at $1,750 and under is planned for next month by the Chicago Motor Club, which to-day announced its card for the coming season. The opener will be a novelty in that it will be the first time special attention has been given to the popular-type car such as is represented in the division up to $1,750. It will be a most thorough test, too, it being the idea of the club to ask the cars to go at least 500 miles in two days, fully as stiff a schedule as was used in the 1,000-mile four-day affair last fall. No exact route has as yet been mapped out nor have the rules been adopted, but the technical committee expects to have the regulatons in shape for publication the latter part of the week.

In addition to this the Motor Club will stage its annual reliability for all classes between September 10 and October 30 at a distance not less than 1,500 miles. Last year the cars traveled 1,000 miles in four days. The annual hill-climb will take place as near August 14 as possible, and again the hills at Algonquin, Ill., will be used. Other events also are planned. One of them will be a skidding test and the other a taxicab demonstration. No dates have been set as yet for these two.

SAVANNAH'S HOPES TELL UNPRINTED STORY.

SAVANNAH, GA., April 8.—That Savannah is depending upon getting the next Grand Prize race can be seen from the work that is being done on the course.

If Savannah is successful in landing the next race, the drivers will find a complete new race course. Instead of having sixteen turns to make they will have only seven, the turns at Isle of Hope being cut out.

Ferguson avenue, which drivers claim to be the fastest section of the course, has been made 60 feet wide, with only an 11-inch grade from one end to the other, and it will be more than five miles long and will save from eight to ten turns. Seventy more convicts have been put to work on the course, these coming from different parts of the State.

AUTOISTS TO CELEBRATE OPENING OF BRIDGE.

NEW YORK, April 12.—Automobiles will take a very prominent part in the celebration of the formal opening of the new Queensboro Bridge. The week of June 12 will be taken up with various festivities, and Tuesday, June 15, and Thursday, June 17, will be given over to automobile sports. The plans call for a non-technical touring contest on Long Island on Tuesday, embodying some new features; and on Thursday a parade of decorated cars across the structure for three prizes, and a cash prize as a refund for the cost of decorating the winner. A committee has been appointed, of which A. R. Pardington, second vice-president and general manager of the Long Island Motor Parkway, Inc., is chairman.

NEW YORK PREPARES FOR CARNIVAL.

NEW YORK, April 12.—But ten days now remain before the beginning of the second annual carnival of the New York Automobile Trade Association, and dealers, owners and many others interested are making active preparations for the various events. The entry blanks for the hill climb and other contests will be issued at once, and the lists of those who have applied for the necessary blanks is evidence of the numbers which will enter. The voting for the king and queen has become spirited, and thousands of ballots have been cast. Arrangements for the parades, the dinner, the smoker and other festivities are nearly completed. The entire week of April 26 to May 1 will be used.

CLEVELAND TO HAVE DECORATION DAY CLIMB.

CLEVELAND, April 13.—The Cleveland Automobile Club announces that its climb of the Gates Mill hill will take place on Decoration Day.

ECHO OF STATEN ISLAND SPEED TRIALS.

NEW YORK, April 12.—An echo of the automobile race on the West Side boulevard, Staten Island, held under the auspices of the Automobile Club of America, on May 31, 1902, was heard on last Thursday when Judge Stapleton in the Supreme Court opened a sealed verdict of $2,500 against the city of New York. The suit for $10,000 was brought by Mary Bogart, wife of John T. Bogart, a spectator who was killed by the fast Baker electric, but the case was never settled until last week.

SEMI-ANNUAL REPORT OF ELECTRIC VEHICLE CO.

HARTFORD, CONN., April 12.—The semi-annual report of the receivers of the Electric Vehicle Company, Halsey N. Barrett and H. W. Nuckols, filed with the Superior Court shows a balance of $151,356.13. Sales and charges on account for the period amount to $215,485.91, with purchases of $187,692.26. Under disbursements, the heaviest item was the pay-roll, which amounts to $160,762.03, materials cost $128,656.46, while the A. L. A. M. is credited with $118,992.64. George B. Selden is credited with $17,492.86.

VANDERBILT RETURNS FROM EUROPE.

William K. Vanderbilt, Jr., the donor of the famous cup bearing his name, and president of the Long Island Motor Parkway, Tuesday returned on the *Kronprinzessin Cecilie* from his Spring European trip. Mr. Vanderbilt declined to have anything to say to the daily newspaper interviewers, but expressed the intention of remaining in this country for the next eight months. Of course, he will give much attention to the completion of the Motor Parkway, and it would not be surprising if a race were arranged for the famous trophy, to take place as usual in the Fall.

CLEVELAND IS BUSILY SATISFIED.

CLEVELAND, April 13.—"How's business?" "Never knew it to be better." That's an almost daily conversation in the trade in Cleveland. From the agents of high-priced cars down to those selling machines for $600, and from the largest dealers in accessories to those selling automobile grease on a commission the answer is the same. Business is good in all lines, and the trade is rejoicing as a consequence. The few warm days that Cleveland has experienced have served to start the automobile fever coursing up and down the veins of local motorists, and the stimulus mentioned is the result.

All the local factories are busy, some day and night, while the same condition holds true in many agencies.

SEATTLE PATHFINDER REACHES COLORADO.

Snow and bad roads have hindered the Thomas car which is laying out the route for the endurance contest from New York to Seattle, but Tuesday evening the crew succeeded in reaching Denver. They were delayed by the conditions at a number of places on their run from Kansas City, and were unable to reach Pueblo on account of the deep snow. It is expected that the party will leave Denver to-day for Cheyenne or Laramie, Wyo., and strike the roads toward the Northwest.

Kansas City was left last Thursday morning, and across the State enthusiastic receptions were met, automobilists and farmers joining in the celebrations. An impromptu reception was accorded the transcontinental travelers at Fort Riley and checking stations were established at a number of places. Pilot cars have been accompanying the Thomas since leaving Missouri and will probably be picked up from day to day.

President Taft has accepted the invitation to press the button which will give the signal to Mayor McClellan, of New York, to start the contestants by firing a golden revolver now being made for the purpose. Up to the present, four entrants have been announced, a Simplex, a Stearns and two Ford cars being listed. Henry Ford surprised the trade with the statement that he will enter two of his model T cars.

Maxwell Completes 10,000-Mile Non-Stop Record Run

Official Starting of the Non-Stop Performer in Front of the Bay State A. A. Clubrooms, March 18.

BOSTON, April 12.—At 10:10 o'clock this morning the autometer on the Maxwell touring car that on March 18 began a 10,000-mile non-stop motor run tickcd off the last fraction of a mile necessary to make the 10,000 total, and a new record for such a test had been established. The completion of the 10,000-mile total came when the car was near Framingham on the return journey from South Framingham. On board the car were the three drivers who have becn at the wheel during the past twenty-five days, C. E. Goldthwaite (who was driving), Arthur Sce and Ellery Wright, and with them was Charles J. Glidden, of globe-girdling fame. On the car flew an American flag, which was given the car just beforc it began its last trip by Mrs. Charles J. Glidden. The flag was one which Mrs. Glidden obtained whilc in Japan on the last motor trip which she and her husband made to the East.

The finish of the 10,000 miles came a little earlier than had been anticipated, the official reception having been arranged for 4 o'clock in the afternoon. On this account the motor was not stopped, but was kept in motion and the car was run about through the suburbs until this afternoon, when the reception incidental to the official completion of the run was held. At 4 o'clock in the afternoon a large number of motorists, including nearly one hundred owners with their Maxwell cars, drove out to Coolidge's Corner, Brookline, about three miles from the city, and there met the car and escorted it into Boston, the procession moving over Beacon street and along Automobile Row, on Boylston street, to Copley square. There, at 4:21 o'clock, in the presence of a large crowd of people, Lewis R. Spcarc, president of the American Automobile Association, who started the motor on March 18, brought it to a stop.

The autometer then showed 10,074 4-5 miles. The car was at once turned over to a technical committee consisting of Professor Parks, of the Massachusetts Institute of Technology; Secretary James Fortescue, of the Bay State Automobile Association, under whose auspices the run was conducted; V. C. Charles, manager of thc Inter-Statc agency, and C. J. Bailcy. This committec is to take down the car, make a thorough examination of all parts, and present its report later.

To complete the 10,000 miles' run the car was engaged just 600 hours 10 minutes consecutively, and all that time, with the exception of the few hours required in the stops to change drivers, take on supplies of gasolene and oil, change tires, and makc a few repairs, the car was in motion, averaging while on the road between 18 and 20 miles an hour.

A total of 679 gallons of gasoline was put in the tank, and 388 3-4 quarts of lubricating oil was used. When the car had been running a little more than a week there was trouble with the off rear bearing, and this was repaired, but owing to the damage that had been done by the broken bearing it was necessary last week to put in a new rear axle. This was the only repair of importance made during the run. One spark plug was replaced and one of thc push rods on the motor which showed an imperfection was changed. Toward the end of the run the muffler fouled, and it was necessary to do some work on that.

The nearest the motor came to stopping was a few days from thc end of the test, when the wires supplying the electric light over the speedometer short-circuited with the wires from the batteries. Fortunately this accident did not interrupt the current from the magneto and the motor did not balk. Though the ignition system was reinforced at the beginning of the run, only the magneto was used while running on the road.

The tire record of the car was remarkable, for in the 10,000-mile trip only eight tires were used, the second set being in good condition at the finish. One of the original shoes was used until the car had been driven about 7,200 miles, and then it blew out. That was the only blowout. There was a small number of punctures comparatively, and they occasioned little delay, for the tires were on demountable rims and inflated tires were carried on the car at all times. Exccpt when the car was in the garage for the work that was done on the axle, and the motor

Justice of the Peace Teele Swearing in the Drivers and Observers of the Non-Stop Run.

consequently was running for some time without a load, it was unnecessary to change or add to the water in the radiator.

The car was driven with care all the way through and the men at the wheel were experienced operators of Maxwells. A high-test gasoline was used and a high grade of oil. With these exceptions and the reinforced ignition system that was not used, the conditions of the run were similar to ordinary operation. No private owner's car, of course, would be subjected to such a test as the constant running of the motor for twenty-five days, and it is figured that the distance covered is at least twice that made in a year by the average owner. The constant vibration of the steady running motor showed its effect toward the end of the test in the breaking of several spring leaves. It was found that the vibration had brought about crystallization of the metal.

The run created a vast amount of interest all through New England, and as Frank J. Tyler, manager of the Maxwell-Briscoe Boston Company, issued a general invitation to people to ride in the car there were few day trips on which there were not one or two passengers. The day and night running was exceedingly trying on the drivers and observers, though there were three shifts, and they were pretty thoroughly tired out this afternoon. They were able, nevertheless, to accept the invitation of Sales Manager Kelsey and the Maxwell company to a dinner given them this evening at the Bay State Automobile Association rooms.

The run began at 10 o'clock in the forenoon of March 18 in front of the quarters of the Bay State Automobile Association, when Mr. Speare cranked the motor. During the first few trips, and when changes of route were made, the car was driven by Lucius S. Tyler, Ralph Coburn and William S. Simonds, of the Boston branch of the company. At other times the car has been piloted by Goldthwaite, See and Wright, of the Maxwell-Briscoe factory force. The official observers were Adam Schneider, Joseph George and C. F. Lawrence. All drivers and ob-

During the first week of the test, in which about 3,000 miles were covered, the car shuttled back and forth between Boston and Worcester. The weather was generally good, and the roads used excellent. On March 25 the route was changed to Providence, and the first night out a bad storm was encountered. The hood was carried away in the wind, and the driver and observer had to repair a puncture in a downpour of rain. The Providence route was followed for five days, bringing the total mileage to about 4,900. Then the car was shifted to Newburyport route, and for three days it was driven back and forth between Boston and that city. April 2, 3 and 4 the car went to Nashua, N. H., and since then it has been running between Boston and South Framingham.

The non-stop performer was fitted with Ajax tires and Continental demountable rims; utilized Splitdorf magneto and spark plugs; its mileage and speed were guaranteed by Stewart and Warner speedometers; and its lubricators were Havoline crystal oil and Keystone grease.

MAXWELL DRAWS THE CAMPBELL TROPHY.

New York, April 12.—At a luncheon given by L. H. Perlman, the first winner of the Chester I. Campbell touring trophy, Friday, at the A. C. A. clubhouse, Carl W. Kelsey was the successful one in the drawing between the 15 perfect score contestants, and becomes the owner of the valuable cup. The lots were drawn by a disinterested person under the supervision of Referee L. M. Bradley, and the last one drawn, No. 20, was that of Mr. Kelsey. Mr. Campbell, the donor, J. K. Mills and T. F. Moore, the managers, were present, and all of the fifteen either in person or by proxy.

Those at the luncheon were: C. W. Matheson, two Matheson cars; Guy Vaughn, Stearns; M. P. Batts, Stearns; H. A. Street, Cadillac; L. B. Le Duc, Cadillac; A. B. Cordner, Acme; W. W. Burke, Mora; J. I. Miller, Cleveland; V. P. Pisani, Zust; Paul Lacroix, Renault, and C. W. Kelsey, Maxwell. Those represented by proxy were: C. S. Carris, Franklin; Ray McNamara, Premier, and Albert Dennison, Knox.

PIERCE-RACINE MAKERS INCREASE CAPITAL.

Racine, Wis., April 12.—Articles of incorporation have been filed at Madison for the Pierce Motor Company, of this city. The capital stock is $300,000, and Charles McIntosh, A. J. Pierce and Frederick Robinson are the incorporators. Mr. McIntosh and Mr. Robinson are heavily interested in, and at the head of, the J. I. Chase Threshing Machine Company, of this city. Mr. Pierce has been for four years at the head of the Pierce Engine Company, and was one of the first builders of gasoline engines in the United States.

The company will take over the entire assets of the Pierce Engine Company, enlarge the plant, and push the sale of Pierce-Racine automobiles, motor boats and motors. Pierce-Racine automobiles are better known in the West than in the East, for the output has always been limited, although Mr. Pierce built his first one in 1893. The marine engines and boats, however, are well known all over the world.

The new corporation starts out under very favorable circumstances; the shops are running with a full force, on full time. There is no liability, and with ample working capital the building of 500 cars will be started at once. The line will consist of one five-passenger car listing at $1,500, one five-passenger car listing at $1,250, a runabout and a roadster.

GIVES KNIGHT-DAIMLER STRENUOUS TEST.

Coventry, England, April 3.—A decisive answer to critics of the new Knight-Daimler slide valve engine has been given by the long endurance trial of two standard engines which has successfully ended to-day. The form of the trial was decided on by the technical committee of the R. A. C. and consisted, first of all, of a continuous full speed run on the test bench for 132 hours, the power developed on the brake not falling below 1.3 times the R. A. C. rating of the two engines, which were standard 22 horsepower and 38 horsepower types.

At the conclusion of this run the engines were erected on cars without any adjustment being permitted, and a distance of 2,000 miles was covered at Brooklands at a speed average of 40 miles an hour. A final run of five hours on the test bench and subsequent examination of the parts by the judges completed the trial. The Daimler company has challenged any other maker to equal this record and have staked $1,250 with the R. A. C.

CONCERNING THE USE OF A PHOTOGRAPH.

Our attention has been called by the Rushmore Dynamo Works to the fact that the photograph appearing in the advertisement of another lamp manufacturer on the back cover of the April 1 issue was made with Rushmore lamps, not with the lamps advertised, as might be inferred from the use of the photograph in that connection. We have learned that this photograph is one of several taken by a Plainfield motorist last fall and that it is copyrighted in the United States and has been authorized for publication only in *The Car*, of London, from whose pages it was reproduced without inquiry as to its source.

In justice to the concern referred to, we must further state that the advertisement originated solely in the art department of this office. The night scene was reproduced from *The Car* for its pictorial qualities, which were recognized to be very exceptional, and with no suspicion that it had originated so near home.

ELKHART CO. MAKES PRATT MOTOR BUGGY.

Elkhart, Ind., April 12.—The Pratt Motor Buggy is the newest output of the Elkhart Carriage & Harness Manufacturing Company, of this city. The machine is constructed with an air-cooled engine of sufficient power to propel the car at a rate of from 25 to 30 miles an hour. The firm has been experimenting for many months with various types, and has given the one adopted a thorough testing on the roads before announcing its manufacture.

Automobile Gasoline and Other Available Fuel

Part I

By Thos. J. Fay

THE amount of gasoline that should be provided will depend upon the design of the car, in any given case, and the motor used. As a concrete example of general practice the following will hold, viz.: (a) single-cylinder motors in runabout types, 5 gallons; (b) double-cylinder motors in light cars, 10 gallons; (c) small four-cylinder motors in roadsters, 15 gallons; (d) light touring cars with four-cylinder motors, 20 gallons; (e) standard touring car work with four-cylinder motors, 25 gallons; (f) the largest sizes of cars with six-cylinder motors, 30 gallons of gasoline.

Radius of Travel of Cars.—Taking the gasoline as above allowed it is an approximation of the situation to say that all the cars will have the same radius of travel, although the following is more nearly in accord with the results obtained in actual practice under average conditions:

NO. CYLINDERS.	MILES PER GALLON.
1	30
2	20
4	15
6	10

There are wide deviations from the above, nor can the differences be ascribed to cylinders alone. The six-cylinder motor, although it apparently uses more gasoline, is generally placed in high-speed cars and the weight, as well as the front area (causing a large wind resistance result) all go toward an increased gasoline consumption. The four-cylinder types of cars, some of which are heavy and go fast, use gasoline in quantity, all the way from 9 up to 18 gallons, considering the best results. The average two-cylinder car will not do quite so well as the table shows, and the one-cylinder car would have to be in fine shape to run on 30 gallons.

At all events it is well to have a good supply of fuel on hand, and in order to avoid annoying interruptions of service it is recommended that some means of determining the rate at which fuel is used be provided. There are a number of devices available for the purpose of showing the gasoline level in a tank, at will, and Fig. 1 shows the design of a tank so contrived that only half of the gasoline can flow to the carbureter without opening a second valve. This tank is usually made of cornice copper, the weight of which should be on a basis of 20-ounce copper for the ends and 16-ounce copper for the shell. The baffle plates can be of the lighter material, although they are generally made of the same weight of copper as the heads. As the section, Fig. 1, shows, the baffle plates *H* and *H* are shaped the same as the heads, and, unlike the heads, they are provided with holes of a good size so that the gasoline can find a level equal in all the compartments. The heads, *I* and *I*, are dished outwards and the hangers should be with a considerable surface, so that they will not tear out at the rivets.

Gasoline is put into the tank through the filler, of good size, *F*, and the cap *G* should be so devised that it may be screwed down tight against a leather packing washer. This material is the best packing to use; rubber will not do at all. If the tank is fed with pressure to furnish the means by which the gasoline is forced into the carbureter the cap *G* must be tight or else the pressure will ooze out. If the gasoline is fed by gravity, a vent hole (about 1-32 inch in diameter) must be allowed for in the cap *G* or elsewhere in the tank, the function of which is to equalize the pressure.

If pressure is fed to the tank, which pressure usually comes from the combustion chamber of the motor, it should be brought in through the pipe *K* and to the bottom of the tank in order that the "spent" products of combustion will be cooled by the liquid, and if there is any flame it will be quenched in the liquid. It is a safety measure to so lead the pressure into the tank, and it will also be prudent to put a screen over the end of the pipe just before it enters the tank.

The gasoline is brought to the carbureter through the pipe *L* and is controlled by the valve *B*. When one-half of the gasoline is used the pipe *A* prevents the flow of any more fuel through the valve *B*, in to the carbureter pipe *L*, so that it will be necessary to open the valve *D* in order that gasoline will flow through the pipe *C* into the carbureter pipe *M*. The carbureter pipe *M* can be joined to the pipe *L* at any convenient point or it would be a good idea to have both pipes lead to the carbureter.

The piping should be large (say, 3-8-inch hole) and of annealed copper. The joints should be limited to necessary terminals and junctions, but all joints should be ground. There are divers forms of fittings to be had, and the joints can be made tight in all of them in which soft packing is not used. In pressure systems especially, it is of the greatest importance to have secure, as well as tight, joints, for the reason that it is extremely difficult to repair trouble of this nature on the road. The motor will not run without gasoline, and in a pressure system the gasoline will not run up-hill to the carbureter, hence the pressure must be prevented from oozing out through leaky joints, some of which are tight when a car is not in use, but owing to design will not stay tight when vibrations are introduced.

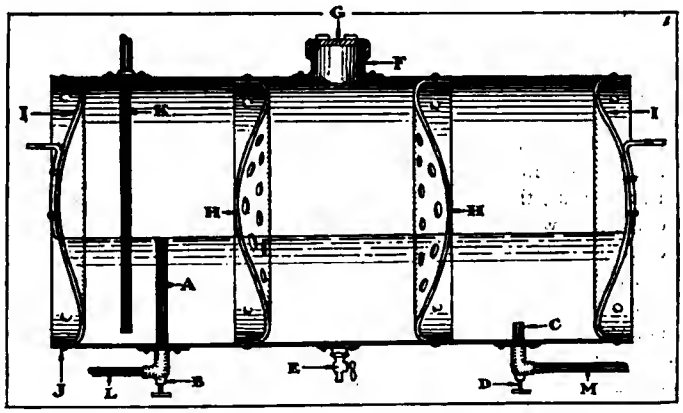


Fig. 1.—Partitioned gasoline tank entrapping a reserve supply.

If the piping is small the chances are that "jelly," which forms out of the contents of the gasoline, will be the source of much trouble, and in the cars, such as use small-diameter piping, the same should be so placed that it can be removed and blown out quickly, and on the road. Even in systems using large piping, if the joints are constricted they will be the cause of the same kind of trouble, with even a chance of the trouble being more acute on the ground that the jelly will form more readily at constricted points.

Water in the Gasoline.—Even if the gasoline is strained through a chamois skin when it is emptied into the tank, if the same is with a vent hole, as required in the gravity-feed system, water will make its way into the tank; moreover, it seems almost impossible to keep water out of the tank whether or not the system is of the gravity-feed genera. At all events the water is a source of annoyance in more ways than one in that if the tank is of steel, rust may form on the bottom, which is the natural resting place for the water. In any event, no matter what material is used in the make-up of the tank, water will not burn, under the conditions in which it is placed in the gasoline tank, and it will interfere with the carburetion to a marked degree.

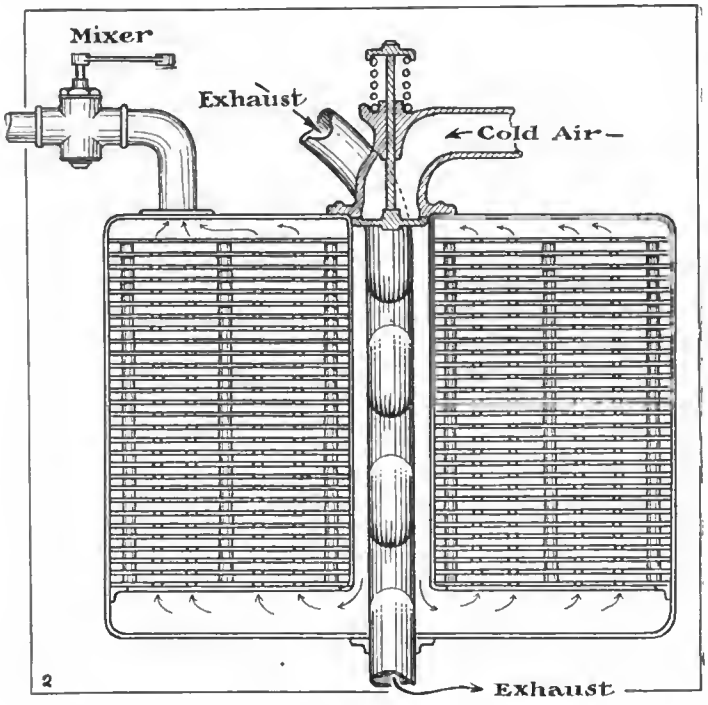

Fig. 2.—Gasoline tank in which the liquid is vaporized by heat.

Since the water will settle to the bottom of the tank—for the reason that it is heavier than gasoline—it is generally the case that the reserve supply is not as good as it ought to be, and the remedy lies in running off the water, through the cock *E*, Fig. 1. In any case, the residuum after a car has been on the road for a couple of weeks is of the heavier fractions of the hydrocarbon distillate, and it should be removed from the tank.

Tanks in Which Gas Is Made.—In view of the uncertain nature of automobile gasoline and the presence of a considerable percentage of the heavier distillates, the ordinary means at hand fall short of the full requirement when reference is had to the complete vaporization of the liquid before it enters the motor cylinder. With a view to the complete vaporization of the fuel before it enters the motor cylinder the gas-producing tank, Fig. 2, is used to quite some extent, and it promises to be a large factor in the future. In this plan, the tank is filled almost completely with wood-fiber boards, superimposed, but slightly separated, so that the greatest possible surface is offered to the hot air as it is drawn through the pile of boards, in which holes are provided for the purpose. The air is taken in through an orifice at the top of the tank, leading to a jacket which surrounds the heater to the bottom and thence upward. The heater itself is devised in a manner not unlike an ordinary radiator, and since the exhaust gases from the motor pass through the heater, the air is adequately heated for the purpose.

The capacity of such a tank is about 55 per cent. of the capacity of the same sized tank, in which no boards are placed. In other words, "voids" in the wood-pulp boards will foot up to about 45 per cent., and the free space makes up the balance. Once the voids in the boards are filled with gasoline, nothing besides can enter, so that there is no danger of an explosion, even when a naked flame is applied to the openings in the tank. True, the mixture, in the space not filled with pulp, could be made "lean" enough to ignite, but it is ordinarily so rich that it will not burn at all. In view of the small amount of space, not filled with pulp, the volume of gas that would be available, assuming it were reduced in richness to the point where it would burn, would not be enough to do damage. In every two-cycle motor mixture is in the crankcase, and the same is rich enough to ignite, as a rule. "Crankcase shots" are not only possible, but they do occur, and what is more to the point, they do no damage. It will be remembered that the compression is but slight in the crankcase of a two-cycle motor, which accounts for the lack of vigor of the burning mixture, but it is a significant fact that the pressure in the crankcase is more than that which obtains in a gas generator, as shown in Fig. 2.

Economy follows the use of any means by which the gasoline is vaporized completely before it enters the cylinder, and carbon formations are aborted. If, then, the gasoline can be vaporized before it leaves the tank there will be ample time for the excesses to condense and the mixture, properly diluted with air, will be suitable for the purpose, taking into account the best results, in which a homogeneous gas, free from liquid, is the more nearly perfect. In the form of fuel holder, Fig. 2, the rich gas passes from the tank to a mixing valve, the function of which is to alter the proportion of air to rich mixture, at the will of the driver, and according to the road condition, or better yet, the speed of the motor. If the motor is to run at high speed, the amount of air should be increased if a carbureter is used, for then the gasoline will be sucked out in greater proportion and the mixture will be enriched in excess unless air is added sufficiently to dilute the same enough to offset the gasoline increase. With the generator, Fig. 2 (gas tank), the reverse holds to some extent, in that the gas will become lean if the amount of gas passing over is increased enough so that the surface available is relatively deficient, as it will be after a certain point in the process. The mixing valve regulates for all these differences, and the motorist adjusts the same in proportion to the needs without having to consider the source of the variable.

In view of the ability of the generator to deliver a gas rather than air with globules of gasoline entrained, Fig. 3 will serve to illustrate a point that ought to find a residence in the mind of any autoist who expects to drive his own car and be awarded a due measure of pleasure or profit. Referring to Fig. 3, *A* represents a gas in which the air is in excess with the result that the phenomenon known as popping in the carbureter transpires. This mixture is quick-burning, due to excess oxygen, and the intake valves, which are generally set to open with a small difference in time, before the opening of the exhaust valves, open too soon for a mixture of this sort. In some motors the intake valves open before the exhaust valves close, and in such cases, especially at low crankshaft speeds, popping in the carbureter is prone to happen.

To avoid this popping it is necessary to enrich the mixture, which is done by allowing less air to pass through the air-port of the mixing valve, and the condition depicted in *B*, Fig. 3, will follow. There is an entire absence of liquid gasoline, just as in *A*, the essential difference being in the ratio of air to rich mixture. In this case, the motor should be able to deliver power at a high speed, and the relation of gasoline to air should be about that due to 8,000 volumes of atmospheric air to one volume of (liquid) gasoline. The condition in *A* will be about on a basis of 10,000 volumes (or slightly under) of atmospheric air to one volume of (liquid) gasoline. As the motor slows down the auxiliary air must be adjusted, primarily to suit the gasoline ratio, and in order to enrich the mixture if it happens to be the desire to slow the motor down to suit road conditions rather than to carry a heavier load. Enriching the mixture will render it slow-burning, and as this process goes on a motor will be slowed down (although it is better to reduce quantity of the right mixture) in which event the density of the mixture will be increased, after a fashion, somewhat as shown in *C*, Fig. 3. When the mixture is so enriched that it will have 3,500 volumes of atmospheric air to one volume of (liquid) gasoline it will not take fire and the motor will fail to run.

It is generally claimed that the greater the weight of fuel entering the cylinders, the greater will be the power of the motor, but it must be remembered that the fuel must be burned completely in order to make this rule hold true. Take, for illustration, the case in which the mixture is enriched in the process of slowing the motor down, this is not on a basis of increasing power. On the contrary, the power is on the decrease (a) because the speed is decreasing and (b) because the fuel is not in the best state to do the maximum work.

Economy Depends Upon Speed.—Since the power of a

motor depends upon the speed, economy in the use of fuel also depends upon speed. That speed is a settled requirement is too well understood to need proof; on the other hand, the relation of speed to torque will stand exploitation at this time, the formula for which may be written thus:

$2\pi = 6.28 = 2 \times 3.1416$, in which $3.1416 = 7/22$ = ratio of diameter to circumference of a circle,

R = radius at which torque is measured, taken in feet, can be accepted as unity in this case,

S = speed of motor crankshaft in revolutions per minute,

P = torque = pull in pounds, in this case, at one foot radius,

33,000 = foot-pounds per minute, equivalent of 1 horsepower,

$H.P.$ = horsepower of the motor.

$$\text{when } H.P. = \frac{2\pi R S P}{33{,}000}$$

$$R = \frac{H.P. \times 33{,}000}{2\pi S P}$$

$$S = \frac{H.P. \times 33{,}000}{2\pi R P}$$

$$P = \frac{H.P. \times 33{,}000}{2\pi R S}$$

The formula shows that, at a constant torque, the power will be directly proportional to the speed; on the other hand, the torque will not remain constant if the fuel is not held to a constant (right) mixture. Taking advantage of this, the fuel is enriched so that it will not deliver the best results when it is desired to slow the motor down in the absence of any considerable power requirement. If the power is to remain in direct proportion to the speed, it is then that the mixture should be held by about 8,000 volumes of atmospheric air for one volume of (liquid) gasoline. When the rich mixture comes from the tank as shown in Fig. 2, it can be "saturated," in which event the ratio of atmospheric air to gasoline will be on a basis in which 15 per cent. of the whole amount of vapor will be vapor of gasoline. This is a maximum value, rarely attained, and in order to show the great extent to which this saturated mixture would have to be diluted with atmospheric air, to make it burn, it is only necessary to say that, when the mixture holds 8,000 volumes to one (liquid) volume of gasoline, it is then the equivalent of 1.8 per cent. gasoline vapor (the balance atmospheric air) in the whole mixture.

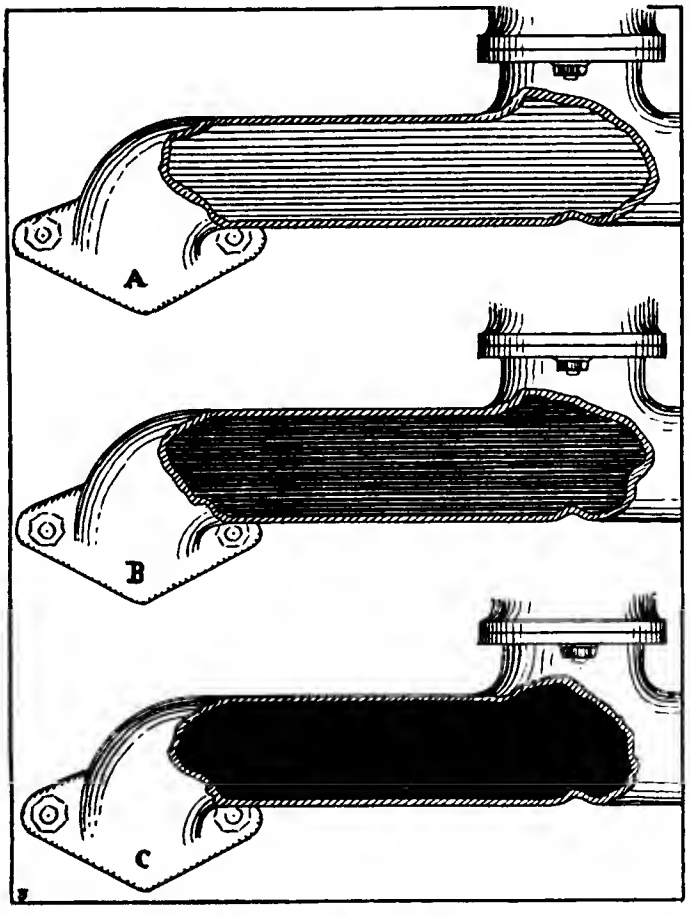

Fig. 3.—Carbureter manifold, (A) showing lean mixture, (B) proper mixture, (C) rich mixture.

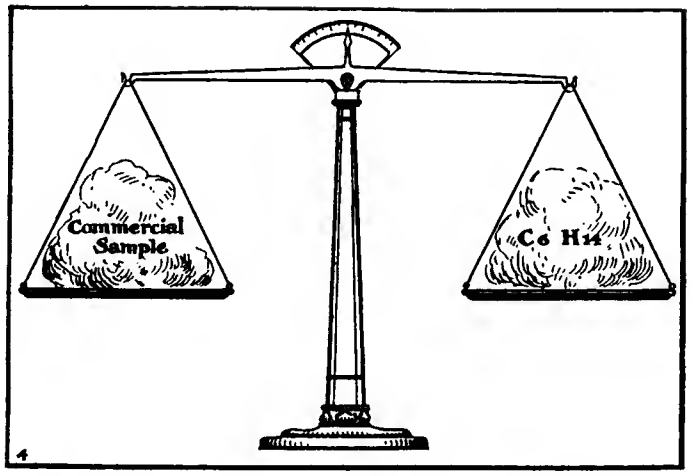

Fig. 4.—Illustrating the principle to use in comparing fuels.

Economy Depends Upon Completeness of Combustion.—As a rule, when a motor runs slow, the fuel economy is materially reduced, although the adjustments can be so made that but little of the fuel will evolve as carbon monoxide, hydrocarbons, hydrogen, carbon, oxygen, etc. When the products of combustion are carbon dioxide, water and nitrogen as the diluting agent, it is then that the fuel will be regarded as in a state called "complete combustion" and the fuel economy, aside from the utilization of the energy, will be a maximum. The effect of load changes on the combustion of the fuel, taking into account speed changes as well, may be noted in the following table:

PRODUCTS OF COMBUSTION UNDER THREE CONDITIONS.

Products.	Full Load.	Partly Loaded.	Slow Speed.
Carbon Monoxide	3.31	6.9	....
Hydrogen	1.19	2.4	....
Hydrocarbons	0.30	0.9	....
Carbon dioxide	11.90	9.9	6.3
Oxygen	0.23	0.3	11.2
Nitrogen	83.07	79.6	82.5
Total	100	100	100

Since the fuel value of the partially burned contents is known it is possible to reflect the losses resulting from incomplete combustion. The value of the unburned products can be set down as follows, subject to slight variation in some cases:

FUEL VALUE OF THE ELEMENTS ENTERING IN.

Carbon burned to carbon monoxide	4,400 B.T.U.
Carbon burned to carbon dioxide	14,500 B.T.U.
Hydrogen burned to water	62,032 B.T.U.
Hydrocarbons burned to carbon dioxide	20,000 B.T.U.

In the above tests of the state of the fuel after use, it is in evidence that, running slow, the air was in considerable excess, thus showing that, instead of running on a rich, slow-burning mixture, the slow speed was brought about by using a lean mixture in which the actual heat units present were barely adequate for the purpose. As the table shows, the best disposition of the fuel was made with the motor running slow, under which conditions there was no carbon monoxide, hydrogen or hydrocarbon fuel in the exhaust.

(To be continued.)

Valuing and Selecting a Second-Hand Car

by A. D. Hard.

THE market price of a partly used automobile does not properly indicate its true value for actual use. Unlike most articles bought for use, an automobile may quickly become unsatisfactory to the owner without fault of the automobile itself. The principal source of dissatisfaction among owners is the desire to secure a later and more stylish model. This notion causes the owner of a really good machine worth probably two thousand dollars to offer it for sale for half that sum. Another reason for selling a partly used automobile at much less than its real value is a desire to have a machine just a little faster, or a little finer than the next-door neighbor on the other side of the "spite fence." Again, a touring car is wanted in place of a runabout, or a steamer is wanted instead of a gasoline car, or a limousine may be desired in place of an open car.

In most of these changes the old car is traded in for what it will bring on the more desirable car, and the partly used car then finds its way into the second-hand car dealer's hands. Sometimes the partly used car will be but little used, not injured at all, and in fact will run smoother and better than a new car. The price usually asked for such a car is far below its real value. I saw a well-known touring car in a popular second-hand shop on Michigan avenue, Chicago, last January, that cost $4,000 less than two years previously, which was marked $900. I examined it critically and found it in first-class condition. Of course, I bought it. In less than thirty days that car was eagerly sought for by two buyers at $1,500, but they did not get it.

As an expert I am frequently requested to give my opinion on the value of a proposed purchase, and the necessity at once arises for differentiation between market value and actual value. The price which a buyer should fairly pay for a partly used automobile depends upon the average price charged for such make and quality of machine. The value for use is quite another and a different matter.

Figures from a Bargain List.—Taking the "bargain list" of a large New York dealer as a basis for making averages, the following figures were deduced. I selected six of the most popular makes and found that he had seventy of these cars for sale, some being old models, some being single cylinders, double cylinders, four cylinders, and part being chain drive. There were nineteen Cadillacs, sixteen Wintons, twelve Fords, nine Maxwells, eight Ramblers, and six Buicks. The average cost price of these cars when new was nearly $1,600. The average price now charged for them as partly used cars was $503. The average time that these cars had been used was sixteen months. Nearly all of these cars had extra equipment, the average value of which I estimated to be $30. This left the average selling price of the cars at $473. From these composite deductions, we find that a second-hand car that has not been used more than sixteen months should sell for not over 30 per cent. of its original cost price. But this must not be a strict assessment of value, for conditions of engine, tires, and amount of equipment must be considered. There are several factors to be considered which do not appear at a casual glance, nor can they be determined by a trial run.

Reliability and Replacements Have an Actual Money Value.—The repute of the maker of a car for turning out reliable products is a very important feature which should not be overlooked. Another factor of value is the possibility of securing replacements when needed. And the probability of ready sale for a fair price in case that you may wish to dispose of it is worth some attention. The maker who turns out thousands of cars will in all probability have a more even standard of mechanical construction than the one who struggles along with an output of fifty cars a year. The manufacturer who makes all the parts which are vital to the quality of his car will be likely to make them well so as to derive a good name as an asset of value for future business.

On the other hand, a manufacturer of automobiles may not have the extensive shop equipment to turn out as good an engine as the man who devotes all his capital and ability to perfecting that special part. To say that every part is made in our own factory may or may not be a true estimate of quality. As a rule, the car that has been abandoned by a manufacturer is faulty. It has not proved to be as good as he expected that it would and he has quit making it. The manufacturer who is constantly changing his model is very apt to be uncertain in his judgment of what is really best in methods of construction and design.

Appearances May Be Deceiving, but Dealers Are More So.—When it comes to examination of the car as a prelude to choice, the man who can buy with his eyes exclusively will be more certain of securing something which will not disappoint him. Not that I mean to say that dealers are all dishonest, but they all look at the transaction from a more or less selfish point of view. Selling second-hand automobiles is fast becoming as proverbial as selling horses, have good eyes and use them.

The cheapest thing on earth is talk, and the next is a catalog with testimonials. The relative cost importance of parts that may be worn and need replacing is a matter of discrimination.

If a car needs a complete new engine, it certainly is not so desirable as one that requires some few inexpensive replacements. Frequently a few of these little replacements will make a car almost as good as new, while without them it will hardly run at all. For want of a minute rubber washer on a tire valve, the tire went flat, the car ran into a tree, and two people were killed. As a rule, lack of compression is considered an awful fault of an engine, when it may be due to worn piston rings which can be replaced for a few cents.

An experienced ear, aided by a physician's stethoscope, will discover burned-out bearings, loose connecting rods, and leaky valves. A noisy transmission may be silenced with thick grease, so remove the cover and look at it. I know of no way to test a differential but by taking it apart and looking at each gear. Nothing about a second-hand car may be so worthless, yet look fairly good, as the tires. The only safe way is to make your bargain so as to cover a new set of tires which are not seconds.

A trial spin in order to see how much power and speed the car may have is of doubtful value to the buyer, although it is a great point for the seller. This applies to new cars as well as partly used ones, for it is an easy matter now to use special fuel for trials in a demonstrating car. The first automobile which a man operates should be a second-hand one, for the first three months' use of a new machine by an inexperienced driver will do it more real damage than the next three years of careful operating. The best way to select a second-hand machine is to get an experienced automobile mechanic to examine the vital parts and make a report as to what replacements are needed to make the car a good serviceable machine, then use your own judgment as to whether on not it suits your needs.

Aeroplanes will beat the Empire State Express, is the remarkable opinion voiced recently by A. M. Herring, president of the Herring-Curtiss Aeroplane Company, during a talk about the future of the flying machine. This concern is now building four machines of a model that is slightly smaller than the Silver Dart, which has flown successfully in Nova Scotia, but with increased power. It is expected that these will be such that they could leave New York City at the same time as the Empire State Express, and beat the train into Buffalo. Experiments will be tried to determine speed attainable.

Which Is Better: Three or Four Speeds?

By Louis Lacoin

WHICH is preferable—a car with *three* speeds, because of its simplicity and the relative smoothness of its running, or one of *four* speeds, despite its higher initial cost and the supplementary complications of its mechanism? That question does not trouble the purchaser very much; the list price alone interests him. With regard to the reasons that have permitted the builder to reduce the cost, or have compelled him to increase it, he is concerned but vaguely. A certain name, a certain power, details of the mechanism that are *a la mode*, influence far more in his choice than the number of gears that the chassis happens to have in its interior. Pay more and then have more lever shifting to do? Thank you. I prefer at the same price a motor that is more powerful. And the builder does not hesitate to place this heavier motor on his chassis. He knows that a few horsepower more will scarcely have any influence on the cost of building the machine, while their presence will permit him to inflate the market price without fear.

But so far as putting a four-speed gear set on the chassis that he builds, he consents to do it on the heavy, high-powered vehicles, because their selling prices are sufficiently remunerative to warrant it. But the small cars? They are the ones on which it is necessary to reduce the cost of manufacture to the minimum. They should have but three speeds. So much worse for the buyer. He cannot comprehend the necessity of being out of pocket several hundred francs for a fourth speed, since that fourth speed strikes him as useless.

But that fourth speed is not useless by any means, as can be proven. First, to begin by justifying the reasoning of the builder in showing what the addition of that supplementary speed leads to in the way of changes on the chassis. In Fig. 1 have been grouped three types of change speed gears. No. 1 represents a type providing three forward speeds and reverse, with the high speed on the direct drive. The sliding member is reduced to the two pinions *C* and *D*, with the jaw clutch *A* for the direct drive. Both the length and diameter of the shafts are moderate; the weight is not great, and the cost can be kept low.

Additional Speed Adds Fifty Per Cent. to Length.—The method of operation of the second arrangement, No. 2, still involves but a single sliding member, but it is almost *half as long again* as the preceding one. The addition of the fourth speed has been responsible for the increase. It must not be thought, however, that the relative distances between the pairs of gears are all the same, and that the fourth pair would accordingly not be responsible for increasing the length more than one-fourth of its previous size. This would be a fallacy.

Take, for example, the three pinions of the sliding member. The gear *B* is actually in mesh with the pinion *P*. That pinion must be a sufficient distance away from the driving gear *M*, so that these two shall not come in contact when the jaw clutch *A* is engaged. The gear *C* of the sliding member, on its part, must not contact with *P*. Between *B* and *C* there must be sufficient space for engagement, plus a length equal to the travel of the jaws of *A*, plus a few millimeters for play. The gear *C* must not contact with the pinion *Q*, when sliding to the right, after *B* and *P* have become entirely disengaged. The pinion *Q* is then distant from *P* a space greater than that from the left face of *B*, to the right face of *C*. Again, the gear *D* of the sliding member must never come in contact with the pinion *Q*, and, as on the direct drive, when *C* is close to *P*, *D* is also close to *Q*, the distance between *C* and *D* is equal to that between *P* and *Q*, and must be greater than that between *B* and *C*. From this it will be evident:

1. That the interval between *B* and *C* is equal to the width of a gear face, plus the length of the direct drive jaws, plus the necessary play.

2. The interval between *C* and *D* is equal to the preceding space, plus the width of *two gear faces*, plus the necessary play, which is also greater.

3. The interval between *P* and *R* is equal to that between *C* and *D*, plus the width of *two more gear faces*, and the play required, this being greater than before.

Fourth Speed Increases Both Speed and Weight.—Consequently the addition of the fourth speed has increased the length of the gear-set by the width of five gear faces, and a number of millimeters for the play required. These shafts, being so much longer, must be made that much stronger and heavier. The gear-set housing must likewise be made capable of carrying a greater weight, from which it will be seen that a four-speed gear-set calls for an entirely different class of work than a three-speed gear. Necessarily, the cost is much greater.

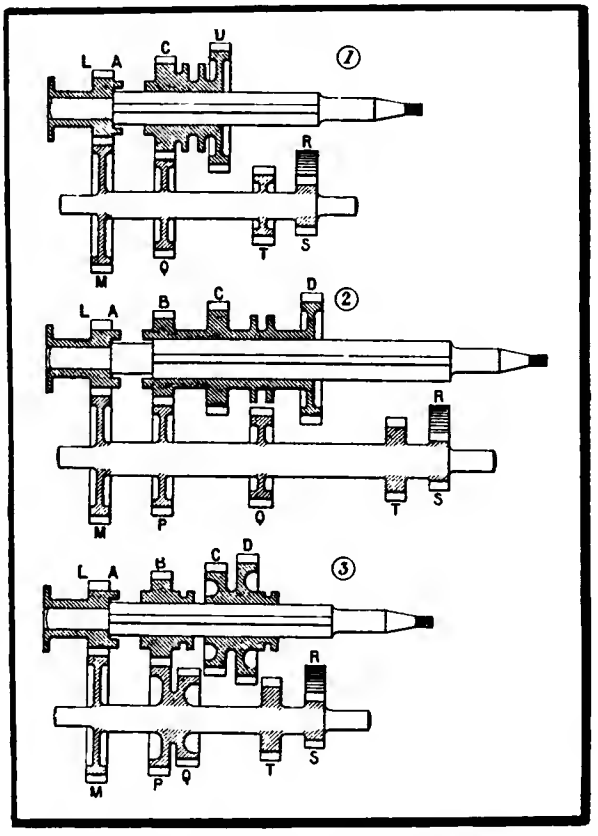

Fig. 1.—Types of change gears: No. 1, three speeds. N. 2, four speeds, one sliding member. No. 3, four speeds, two sliding members.

Thus far our attention has been confined to a type of gear-set having but a single sliding member. It is possible to make it with two sliding members, or even with three. The size of the gear box may then be reduced. See No. 3. But the interior complication and the more involved method of operating the sliding members, far from diminishing the cost, greatly enhance it. There is no difficulty, in view of this explanation, in understanding the hesitancy of the designer to thus increase initial cost.

Let us see what end this fourth speed serves. It is not with the manufacturer that the question will be discussed, but with the buyer. Take, for instance, two machines, identical in every respect, except the number of speeds with which they are pro-

*Translation from the French of "Omnia."

vided. Both are of the same weight, have motors of the same power, and both have the same type of gear-set, except that one has four and the other has but three speeds. Take the three-speed car first. The choice of these speeds is not a matter of indifference, as our analysis will show incidentally, though this is not the place to discuss that. Assume that the speeds chosen are the conventional ones of 16, 28 and 48 kilometers (10, 17½ and 30 miles) per hour. Assume the car to be on the road, with the second speed engaged. Will the motor then propel the car at exactly 28 kilometers (17½ miles) per hour? It will, if it happens to be on a 7½ per cent. grade, as under these conditions, the motor will develop its full power. But if the grade be less, the speed will no longer be 28, but 30, 33 or even 35 kilometers (18½ 20½ or 22 miles) per hour, at which the motor, being less heavily loaded, will drive the car. On a stiffer grade the speed will, on the contrary, diminish, and if we wish to climb a grade stiffer than 10 per cent. it will stall.

The curve *A B E C N D*, Fig. 2, represents the speeds which the car in question will make on the different grades with the second speed in engagement. During this period the motor will turn at a series of speeds corresponding to those of the vehicle. But at all these speeds, with the exception of the first, it will not furnish

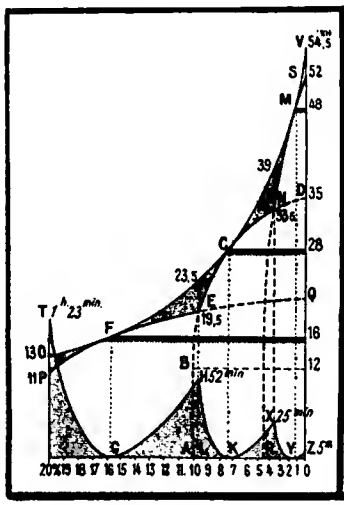

Fig. 2.—Showing time losses with three speeds.

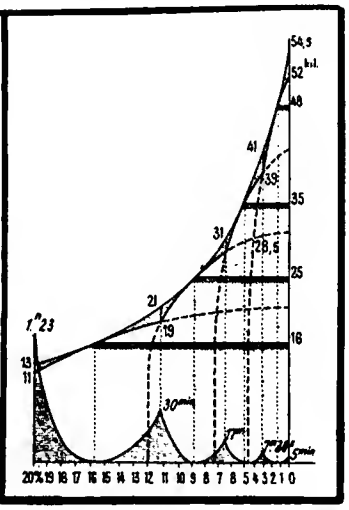

Fig. 3.—Showing time losses with four speeds.

its maximum power. Its maximum output will correspond to the point *C* of the curve *A B E C N D*.

Shifting into first speed, we will then have a new curve *P F E Q*, with *F* as the point of maximum power. On the third speed we would have the curve *X N M S*, with the point *M* as the peak representing the maximum power delivered by the motor. If free to take any gear ratio, the points *C, F* or *M* of the curves corresponding to each one of these gear ratios would form a new continuous curve *U F C M V*. That curve would represent the speed at which the motor, turning at its best r.p.m. rate and developing its maximum power, would drive the car up the different grades.

It will also be evident that on a 9.6 per cent. grade the car would attain a speed of 23.5 kilometers (14.6 miles) per hour, while on the first speed, curve *P F E Q*. On the second speed, curve *A B E C N D*, it will only reach a speed of 19.5 kilometers (12 miles) per hour. Not having all speeds, 4 kilometers (2½ miles) an hour is consequently lost. If there was 100 kilometers (64 miles) to run on such a grade, it would mean the loss of almost an hour in making it—to be exact, 52 minutes, taking 5 hours and 8 minutes, instead of 4 hours and 16 minutes. So far as the owner's pocket is concerned, the result is the same as if the motor had been run under full load for 52 minutes, without propelling the car. If the motor were one of 12 horsepower, it would mean 5.2 liters (1.14 gal.) of gasoline wasted.

Loss Is Less on Lower Grades.—But grades of 9 per cent. are rare; take one of only 3.6 per cent. The loss in 100 kilometers (64 miles) will be 25 minutes, or 2.5 liters (.55 gal.) of gasoline. The curve *T G H K X Y Z* represents the loss of time in 100 kilometers, which the three-speed gear-set, chosen with the speeds in question, would cost. Why not then choose others? Everything depends upon the nature of the ground to be covered. If, as is usually the case, the rises are short, and the easy grades far more numerous than the bad ones, we could have favored them in our illustration, by making the second speed very much higher. In a rolling country it would be necessary to diminish the value of these speeds in such a manner as to reduce the loss of time on the heavy grades, and increase it on the others; *T* and *H* would then be lowered, and *X* and *Z* raised.

For lack of more definite data, let grades ranging up to 8 per cent. be assured. The average loss of time in 100 kilometers will then be 12 minutes, and the loss of fuel for the same distance will be slightly more than one liter—1.2 liters (.26 gal.), to give the exact figures.

It will be well now to consider the four-speed car, Fig. 3. Assuming the same basis of desiring to favor the light grades, choose speeds of 16, 25, 35 and 48 kilometers (10, 15½, 22 and 30 miles) an hour for the first to the fourth speeds, respectively. The maximum power curve remains the same, as well as the curves for the extreme speeds, 16 and 48 kilometers per hour The two curves of 25 and 35 kilometers per hour have replaced the former single intermediate of 28.

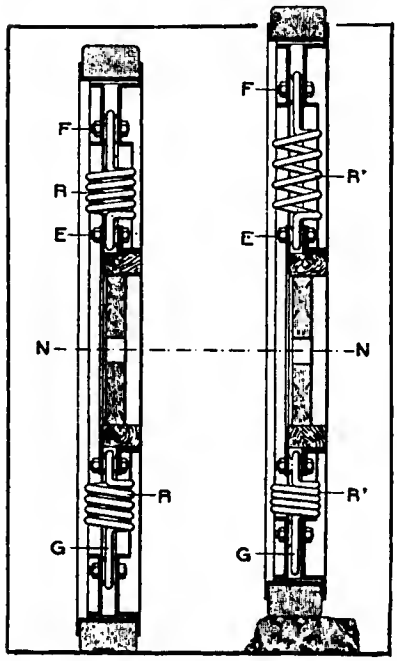
Fourth Speed Saves Enough Fuel and Time to Pay Its Way.—These curves follow very closely the curve of maximum power, while the fuel and time losses per 100 kilometers are greatly reduced. It is found, as a maximum, 30 minutes on a grade of 11 per cent.; 17 minutes on a grade of 6.2 per cent.; 7½ minutes on a 3 per cent. grade, and 5 minutes on rises less than this. The mean average of these losses on grades up to 8 per cent. in 5 minutes, and half a liter (.11 gal.) of *essence*. By having four speeds, 7 minutes and .7 liter (.15 gal.) of fuel per 100 kilometers have been gained. Let it be supposed that only 20,000 kilometers (12,400 miles) in a year are covered. The gain is 1400 minutes, or almost 24 hours of driving, and 140 liters (31 gal.), or at least 52 francs in fuel ($10.40) in actual running (outside of Paris), without considering the matter of lubrication and wear on the motor, during those 24 hours of useless running. due simply to that fourth speed.

On the other hand, let it be assumed that the mean possible speed, the power of the motor being given, is 40 kilometers (25 miles) per hour. If there are three speeds, that will be lowered to 37 (23). With four speeds, instead of 40, we will have 38.7 kilometers (24). The fourth speed will then be equivalent to the practical increase of 5 per cent. in the power of our motor. To the economy of time might be added that the saving of fuel is almost one liter (.22 gal.) per 100 kilometers, so that we must recognize that this extra speed is well worth the small amount of space it demands on the chassis, and that it has the right to pay for its presence there.

"Machine Drawing and Design for Beginners."—In this work on a time-worn subject the publishers, Longmans, Green & Company, have succeeded in getting a new style of treatment which is unusual and effective. The author is Henry J. Spooner, C. E., a well-known English engineer and writer on engineering subjects. The text is divided into 26 chapters, each devoted to a different subject which is thoroughly handled and completed before taking up the next. The method of treatment is as follows: the subject is defined, then discussed, then the ordinary points are called to the student's attention and their treatment clarified. Next the more difficult questions are taken up in a similar manner and finally the subject is closed. Drawings illustrate every point made and no less than 14 useful tables are given. At the close of every chapter exercises are given of a numerical, drawing and sketching nature. These carefully follow the text, but at the back are given a miscellaneous lot of problems covering the whole work. It is an excellent book for the purpose, mechanical drawing self-taught, or equally good for class instruction.

FRENCH SPRING WHEEL APPEARS MERITORIOUS

FROM the very birth of the automobile there have been produced spring, elastic and other flexible wheels designed to eliminate the pneumatic tire and all attendant troubles. These have possessed merit sometimes, others were only ingenious and not practical. The latest to be produced among the French, always large producers in this particular line, is the Lipkowski. This has, says *Omnia*, an interior portion carrying the axle and a felloe or exterior part carrying the rim and demountable solid tire. The two are united by means of a number of small diameter coil springs, 12, to be exact. They are arranged in sets of three each, placed between the arms of the interior part. This part is a built-up member and projecting arms are riveted between the two portions, which go to form the hub.



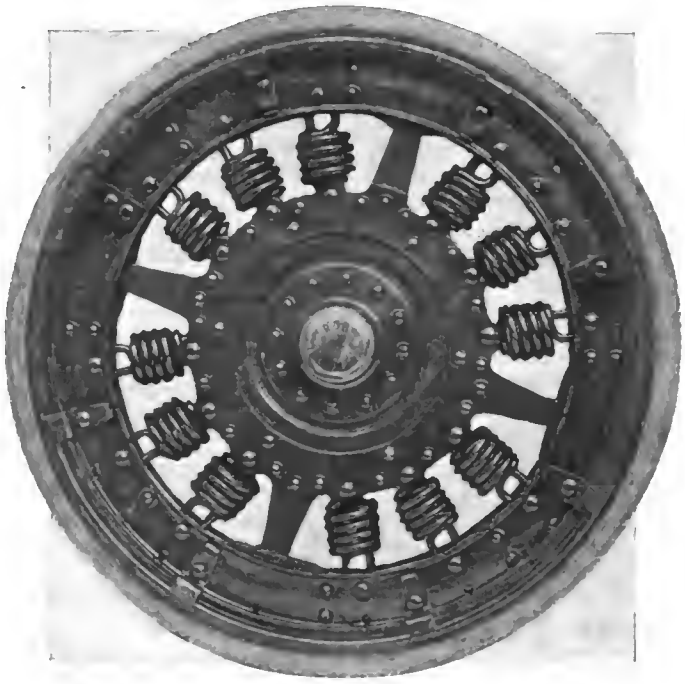
Section Illustrating the Action.

The arms are of steel and case hardened to care for possible wear. They are free to slide up and down as well as sideways, but only to a very limited distance. The rotative or sideways sliding motion is limited by a pair of abutments or projections, while the other motion is restricted by the springs. These will restrain the rotative motion, making it gradual and progressive. Shocks would destroy the projections which may not have a large cross-section.

The springs are coils of a small diameter and with the size of the wire proportioned to the load, small for light touring cars and runabouts, large for heavy enclosed cars or trucks. The two eyes for attachment are turned into a plane parallel to the flat side of the wheel and differ. The inner end is perfectly circular and just fits the bolt upon which it is mounted, so that there is no play at that end. The outer end is elongated and consequently has a little freedom.

This comes in when the wheel runs over an obstruction, as shown in the sectional drawing. The interior part with the axle does not rise but continues in the same horizontal plane. The felloe portion rises, thus drawing away from the inner part at the top and approaching it at the bottom. The first action exerts tension on the upper spring, stretching it. The second part of the movement compresses the bottom spring, First, the elongated eye gives or slides the length of the elongation. A further movement results in pressing together the coils.

In this way the inner wheel is suspended within the outer, the outer taking all road shocks and altering its position relative to the inner without actually disturbing it or the axle which it carries. The outcome of this is the desired result, easy riding qualities with solid tires. A set of these wheels on a heavy limousine car of 40 horsepower was driven 10,000 kilometers (6,210 miles) among the Alps and through other mountainous parts of Switzerland and Italy. On this long tour the inventor had with him three or four friends, so that the car was well loaded at all times. The riding was said to be very comfortable at all times and the only outcome of the trip was the necessity for replacing two broken springs.



View of the Lipkowski Wheel, Showing the Springs.

These cost 18 francs ($3.50) and their replacement occupied but 11 minutes. It is hard to imagine a similar trip on pneumatics with any less expense and an equally low amount of lost time, so the statement is fair that the merits of the wheel have been proven by actual, severe test.

SOME POINTERS REGARDING THE CARE OF TIRES

SIDE slipping and wear is due to spreading of the front wheels, generally caused by a bent distance rod or drag link connecting the steering arms or knuckles. If this condition is present, even in a comparative slight degree, the strain and wear brought upon the tire will quickly wear out the tread, inasmuch as the side slip continues with the rotation of the wheels. In case of excessive tread wear, examine the front wheels and find if they take proper position for straight ahead running.

Deterioration, due to chemical action, or rotting of the fabric lining, is usually caused by water or dampness, and is most likely to occur in tires which have been stored away for the winter. Water will penetrate even a comparatively insignificant cut in the tread, and being absorbed by the fabric a gradual breaking down of the tire and disintegration will result. It is important for this reason to keep the tires in good repair.

Extra shoes and tubes should be protected by cases from the light and dust. Inner tubes in particular should be given proper care. When not in use they should be partly inflated and placed inside the spare shoes. Extra tubes should be spread upon a table with the valves spread half-way, and rolled up with the valves on top. Talcum or soapstone powder should then be freely sprinkled in the folds.

E-M-F Fire Fighter for Tampa's Fire Chief.

TAMPA'S FIREMEN GET THEIR NEW AUTO.

TAMPA, FLA., April 10.—Desiring to be thoroughly up-to-date in its equipment, the fire department of this city has received through the Tampa Harness & Wagon Company, the local agents, an E-M-F "30," a tourabout, equipped with four fire extinguishers, lanterns, axes and other fire-fighting paraphernalia for the use of the chief. The photograph shows Chief A. J. Harris seated beside the chauffeur, and directly behind him sits the assistant chief. Standing in the rear of the car is T. N. Henderson, manager of the Tampa Harness & Wagon Company. This car was the first E-M-F delivered to a Florida dealer, and is the first one in commission in that State, the wide tread that is required for Southern use on sandy roads making deliveries slower here than in the North.

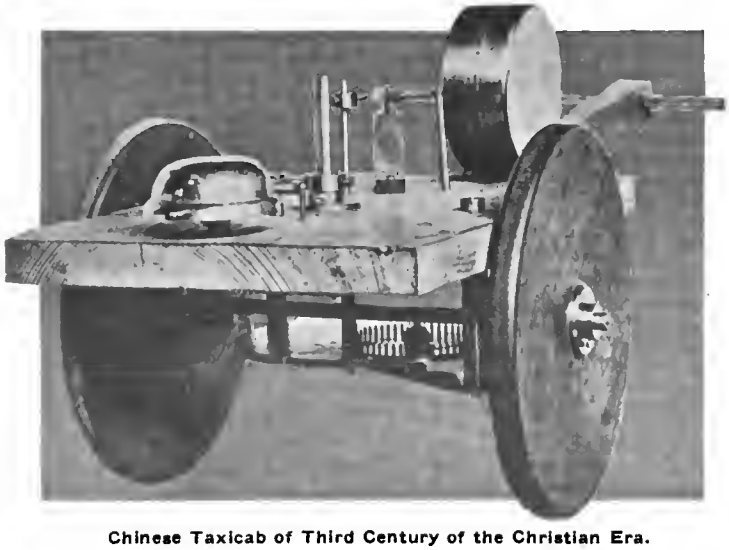
CHINESE HAD A TAXICAB IN A.D. 265.

Professor Giles, of Cambridge University, has discovered in the dynastic histories of China a full specification of a taxicab dated A. D. 265. A model of the chassis has been made by Professor Hopkinson. The existence of such a vehicle has been hinted at several times in the past few years, and, in the research, Professor Giles came across the following reference to it in the history of the China dynasty (A. D. 265-419):

"The measure mile-drum-carriage is drawn by four horses. In the middle of it there is a wooden figure of a man holding a drumstick towards a drum. At the completion of every li the man strikes a blow on the drum."

Under the years A. D. 815, 830 and 987, they again heard of the taxicab, and the following further description was given:

"They are painted red, with pictures of flowers and birds on the four sides and in two stories, handsomely adorned with carvings. At the completion of every li the wooden figure of a man in the lower story strikes a drum, and at the completion of every ten li a man in the upper story strikes a bell. There is a pole with a phœnix-like head and a team of four horses. Formerly the chariot held 18 soldiers, which number was increased in 987 by the Emperor T'ai Teung to 30."



Chinese Taxicab of Third Century of the Christian Era.

The taxicab was again to the front in 1037, when an account of the mechanism was given, and even so late as the fourteenth century they read of a well-known poet who wrote a poem entitled "Ode to a Taxicab" in its praise.

ANOTHER COMMERCIAL FIELD FOR THE AUTO.

CLEVELAND, April 12.—The use to which the Auto Renovator Company of this city has just put their White steamer is decidedly novel, to say the least. A special body was built and placed on the rear end of the regular chassis. Within this is placed a dynamo and the necessary regulating devices. In use, the cleaning of houses by the vacuum system, the car is driven to the house where work is to be done, the dynamo belt is then put on, so that current is generated, this being connected to the other apparatus by means of wires. This is the up-to-date way of handling the cleaning problem, and is said to be far superior to the old and noisy vacuum apparatus.

Vacuum Cleaning Outfit on White Steamer Chassis.

To attract attention and thus business the car is equipped with a very large set of Gabriel horns. When going along the street to or from work the horns are played, the skilled operator being able to produce all of the popular airs and attract a proportionate amount of attention.

MAIL WAGON AND FIRE TRUCK FOR AKRON.

AKRON, O., April 12.—For a town of its size Akron can pride herself on being just as up to date as many a larger place. The recent events which have led up to the statement above are the call for bids on an automobile fire truck by the Board of Safety, the construction of an appropriate house for the same, and the very successful trial of a Brush mail wagon similar to those now in use in Washington.

This test lasted something over twelve hours, during which time the car covered 13 runs, totaling 35 miles, and made 322 stops. In this time the same work was done as ordinarily takes three men and three horses. The result was highly pleasing to Superintendent Schick, who personally accompanied the car. He was so much pleased that he will immediately place an order for a duplicate of the car used on the test.

The many large tire factories are so widely scattered that good service with horses is practically impossible and there have been many complaints. It was the result of these complaints that caused the present trial. The product of one of the tire companies helped to make the test a success, the Metz clincher tires going through without a particle of trouble.

Letters Interesting and Instructive

CARBURETER WATER JACKETS.

Editor THE AUTOMOBILE:
[1,830.]—Will you please explain the functions and necessity of water jackets for carbureters? Also the necessity for hot air supply to the carbureter, which is used on many cars. READER.
Allegheny, Pa.

The chemical action of converting a fluid into a gas is accompanied by the absorption of heat. If no extra heat is furnished, the action of absorbing heat from the air will freeze the moisture in the air and this collects on the outside as a sort of snow or frost. That in turn retards the vaporization. So, heat is furnished from the handiest source. On some cars this is the hot jacket water and on others the heat of the exhaust pipe is used. It is very seldom that both are utilized on the same cars.

The purpose of making the carbureter with a jacket is to allow the use of the hot water if desired. All carbureters so made may also be had without the jacket. The majority of drivers prefer to do without this external heat supply in summer or in warmer climates.

COLOR TELLS THE STORY.

Editor THE AUTOMOBILE:
[1,831.]—Will you please tell me what the color of the exhaust indicates; that is, how can you tell from its color what is wrong?
Baltimore, Md. STUDENT.

The exhaust from a perfect mixture is practically colorless. When the exhaust has the form of a dense smoke it may indicate one of two things. Either you are using too much lubricating oil, in which case the smoke will have a blue color, or else you are using too much gasoline, when the smoke will be more black and contain much soot. If the former is the trouble, you may not be able to remedy it at once. The whole system will be so full of oil that it will not burn out in a few minutes. The waste of fuel, on the other hand, can be remedied at once.

ONE PLUG WON'T SPARK.

Editor THE AUTOMOBILE:
[1,832.]—Will you please help me out of a little ignition trouble? My four-cylinder engine is ignited by means of a magneto, coil and regular spark plugs. Number one and three fire all right, but cylinders two and four will not fire as they should, although they sometimes spark. Can you tell me what is the most likely source of trouble, so that I can fix it? R. E. PAIR.
Torrington, Conn.

There are a number of likely sources of trouble in your case. First, the insulation of the wires to the cylinders which are at fault may be defective. Defective insulation may be due to moisture, as water or oil, wire touching metal so as to ground the circuit, or the insulation in the two sections of the coil may be partly broken down. Second, you may have loose connections in those two circuits, at the plugs or at the coil. Third, the spark plugs may be defective. A cracked porcelain will cause trouble like this. Or the insulation on the plug may be partially broken down so that the plug is fooling you by sparking all right in air but won't jump correctly in the higher pressure of the compressed mixture. In the latter case, the current will leak through the defective insulation of the plug rather than jump the air gap.

These are the principal sources of trouble in a case like yours and of them all you will find the defective insulation within the coil the most elusive and, at the same time, the most troublesome.

GASOLINE ATTACKS RUBBER.

Editor THE AUTOMOBILE:
[1,833.]—In the March 25 issue of "The Automobile" was printed a description of a tire inflator, which utilized the compression from one cylinder of an automobile engine. It being a well-known fact that gasoline, as well as oil, has an injurious effect upon rubber, it seems to me that the carbureter air which this device pumps into the tires, containing gasoline as it does, would have the same effect upon the inner tube.
If I am mistaken about this, I would be pleased to be corrected, as I have received several inquiries on the practicability of such a device.
Youngstown, O. E. F. McNUTT.

Regardless of any merit or demerit of the particular device in question, the fact exists that gasoline always and under all conditions attacks rubber. So any mechanism which introduces gasoline or its vapor into a tire would have a more or less destructive effect. Experience will tell the exact result in this specific case.

WHAT IS A CYCLE?

Editor THE AUTOMOBILE:
[1,834.]—Will you please advise me through "Letters Interesting and Instructive" the meaning of the word cycle as used in connection with automobile engines?
INTERESTED READER.
Chihuahua, Mexico.

Webster defines a cycle as: An interval of time in which a certain succession of events or phenomena is complete, and then returns again and again, uniformly and continually in the same order. In the automobile engine, the phrase used at first was two-stroke cycle, four-stroke cycle, etc., but now the word stroke is usually omitted. These phrases were used to indicate the number of strokes in which the succession of events necessary to the operation of the engine, viz., suction, compression, expansion and exhaust, were completed. Until very recently there were but three of these phrases: two cycle, four cycle, six cycle. A French engine described on page 314 of THE AUTOMOBILE for Feb. 18, however, works three cycle.

RED-HOT EXHAUST PIPE.

Editor THE AUTOMOBILE:
[1,835.]—Will you please explain what is likely to cause the exhaust pipe on my car to become red hot as it does? I am a careful driver and do not like it to do this, although there is no real harm done. J. T. D.
Yonkers, N. Y.

There are four possible causes for your trouble. First, the muffler may be clogged. Second, you may be driving too much on the low gear. Third, your exhaust may be throttled too much either in the pipes or in the engine. Fourth, it is possible that you drive too much with a retarded spark. The first can be remedied by taking the muffler off and cleaning it. The second and fourth you can change even easier than that. The third, on the other hand, will require some study and possibly some work. If the exhaust is throttled in the engine, other than changing the valve timing so as to hold the exhaust valve open longer, you can do very little. If it is in the pipes, you can change the bends and make the passage of the gas easier.

THE THREE-SPEED PLANETARY.

Editor THE AUTOMOBILE:
[1,836.]—Will you tell me if there are any three speed and reverse planetary transmission in actual use in this counry, and if so, who uses them? AUTOCAR.
Belleville, Kan.

To our knowledge there are no cars built in this country so equipped, but in England a car has been brought out recently with this form of transmission. That is, it is called a three-speed planetary but correctly speaking there is no epicyclic action except when the reverse is engaged. No internal gears are employed in the construction and although a series of planet wheels is used, in the generally accepted sense of the word, this is not a planetary.

The big trouble with the three-speed planetary is the complications attendant upon its construction and the great flywheel effect when the whole transmission is revolving as a unit. The weight is increased very materially by the transmission itself and by the additional control necessary. The latter is a complication over the two speed form. Summed up, the advantages are few and the disadvantages many.

COMPACT ARIES ENGINE.

Editor THE AUTOMOBILE:
[1,837.]—Will you please answer the following questions relative to the Aries engine described in the February 18 issue of "The Automobile": (1) What are the advantages of this motor over an ordinary four-cylinder motor? (2) What is the relative balance of a motor of this sort and what is the firing order? (3) What firm makes it and where are they located? R. S. O'HARA.
Wilkes-Barre, Pa.

(1) The great advantage of this engine consists of the small space which it takes

up and the obtaining of two impulses per revolution. The length of the space occupied is nearly one-half of that taken up by an ordinary engine of the same power.

(2) The firing order is: Front right, rear right, front left, rear left. This brings the first two impulses 180 degrees apart, 165 to the next, then 180 again, 195 back to number one. The construction is such that it is similar to the two-cylinder, two-crank engine. The balancing is: Primary forces balanced, primary couple unbalanced, secondary forces unbalanced. Owing to the arrangement of the three-crank discs within the case, a heavy fly-wheel effect is obtained which makes the value of the balanced primary forces very great in comparison with the others.

(3) It is made by the Société Anonyme des Automobiles Aries, 39 Quai d'Argenteuil, Villeneuve-la-Garrone, France.

TWO-CYCLE MAGNETOS.

Editor THE AUTOMOBILE:

[1,838.]—I desire to build a three-cylinder two-cycle engine, and want to use a magneto for ignition. Will you please tell me whether to use a three- or a six-cylinder magneto, and how to connect it up to the engine? Will it be necessary to use two sets of spark plugs? How fast must the magneto run compared with the crankshaft? I have a six-cylinder magneto which I would like to use if it is possible, as that will save my buying another. A. D. SOFT.

New Rochelle, N. J.

To answer your question rationally it will be necessary to select a firing order for a six-cylinder four-cycle and a three-cylinder two-cycle. Suppose this be taken as 1, 5, 3, 6, 2, 4 for the six and 1, 3, 2 for the three. The whole number of cylinders is fired in two complete revolutions in the former case, while in the latter they are all fired in one complete revolution. Therefore to put them on a comparative basis it will be necessary to consider two complete revolutions in the latter case. This would make the firing order read 1, 3, 2, 1, 3, 2. Now, if you have a six-cylinder magneto it is geared to fire all six cylinders in one of its own revolutions or one-half of the crankshaft speed. In using this same magneto on a two-cycle three-cylinder engine, if geared the same as before, you would get six sparks per magneto revolution, which is per two crankshaft turns. As this is the required number to spark each of three cylinders twice, all that will be necessary is to provide two sets of spark plugs and connect them to the magneto so that they are used alternately.

Thus, the first turn of the crankshaft will produce a spark in each cylinder using the first set of plugs. Then the second set will come into use on the second turn of the shaft, and so forth.

If you did not have the six-cylinder magneto on hand, it would probably be preferable to purchase a special three-cylinder magneto and so gear it as to turn at crankshaft speed, which would give you the same results, viz., three explosions per revolution. In that case the extra set of plugs and the wiring would be eliminated, simplifying the whole ignition system, and the wiring from the magneto would be so simple that it would be impossible to make a mistake. To return to the firing order in the case of the three, the magneto leads would have to run to cylinders 1, 3, 2 of the first set, then 1, 3, 2 of the second set.

Some magneto firms furnish magnetos in multiples of two only, varying the speed to care for cases like three cylinders or other odd numbers. These would not give you any trouble, however, as instructions are furnished with each instrument sold.

In the case that the magneto which you have is wound to turn at one and a half times the crankshaft speed for a four-cycle, it will only be necessary to run it at the same speed for a two-cycle of half the number of cylinders as brought out above.

HOW TO VAPORIZE KEROSENE.

Editor THE AUTOMOBILE:

[1,839.]—Will you please tell me the general principles of the vaporization of kerosene and why it is not more generally used for automobiles? A. B. DUGAN.

Jersey City, N. J.

The principal reason why kerosene is not more generally used is because of the lack of suitable vaporizers. To gasify any of the heavier hydrocarbons, a great deal of heat is necessary, much more than that furnished by air in the case of gasoline. In the usual kerosene carbureter, the fuel is heated previous to spraying it into the mixing chamber, by using the exhaust, circulated around the kerosene inlet. It is then atomized, in a chamber which is also furnished with a source of heat to assist that action. A second method is to compress the air only to a very high, an excessive pressure, within the cylinder and then spray the kerosene into that highly compressed and highly heated air. This heat ignites the entering stream of kerosene spray. The method employed in the Diesel motor is very similar to this.

The greatest disadvantage of the use of kerosene is starting. For this, the mixing device must be heated with a torch or else gasoline must be used to start on. A majority of automobilists finding it necessary to use gasoline for starting will use it for running sooner than bother with two fuels.

THE AREA OF MUFFLERS.

Editor THE AUTOMOBILE.

[1,840.]—I am having trouble with my muffler so will ask you to please answer a few questions relative to the same. Should the area of the muffler be less than the area of the exhaust pipe leading to it? In the case of mine, the cubical contents of the muffler are but one-half of the volume which is swept out by the piston. Should this be so? Moreover, the area of the small openings out of the muffler into the air is less than one-fourth of the area of the exhaust pipe. Is not this wrong in principle?

Dayton, Ohio. JOHN O'BRIEN.

An increase in pressure is accompanied by a corresponding decrease in volume, and the reverse of this, a decrease in pressure, always shows an increase in volume. These are natural, unchangeable laws. In the case of a muffler, the gas entering it from the engine is at a high pressure, say, 35 pounds per square inch. The volume is accordingly low. The object of the muffler is to reduce this pressure to atmospheric or as close to it as practical. Let us say that the object is to get a terminal pressure of 16 pounds per square inch. The volume will be increased proportionately.

So instead of a decrease in the volume of the muffler pipes what is wanted is a large increase. It is hard to see how the area of the muffler can be less than that of the exhaust pipe, as per your first statement. In the matter of your second statement, the cubical contents ought properly to be about twice the pipe, rather than the one-half of your case, so you should enlarge yours four times. Relative to the area of the small final openings these should be the largest of all, if volume only be considered, as at that point the volume is at a maximum. But it is usual here to consider the speed, by increasing which the induction effect is increased. As the work of reducing the pressure has been completed at this point, the reduction necessary to effect a much higher speed of the gases does no great harm.

MORE TIRE INFLATION.

Editor THE AUTOMOBILE:

[1,841.]—Will you please give me further information about Mr. Maxim's tire inflator, described on page 516 of "The Automobile"? He takes gas from the inlet valve on the compression stroke and is therefore using explosive mixture to fill the tire. What effect will gas of this quality have on my tires? Does he not also get a little gas that has been exploded? He uses a check valve above the cylinder stop-cock undoubtedly.

Grafton, Mass. SUBSCRIBER.

As far as the explosive character of the mixture is concerned, but does not make any difference. The illustration of the device shows the check valve above the ordinary cock. Your other questions were answered in the answer to E. F. McNutt.

TO ERADICATE AN EVIL.

[1,842.]—The chauffeur is at the present time getting his semi-annual raking over the coals regarding speeding. They are arresting them quite fast now, and at least they help to raise the debt the city is now in.

When we read in a newspaper how a chauffeur runs over and kills someone, we all line up to have his life for speeding; maybe he was going fast, and maybe not. At any rate, he can choose between being mobbed to death or to escape, and at a moment's thought he speeds away, naturally leaving no doubt that he was responsible for the accident.

Now, if all chauffeurs, when they have an accident, would only stop and ask for witnesses, and give local aid, this idea of lynching would soon leave the people and they would begin to think that maybe the chauffeur is not all at fault. And the judges would not doubt his word so much.

There is no doubt that a good many accidents now occurring could be easily avoided if the public at large would use their eyesight more when crossing an avenue or street, instead of plunging before an automobile or any other vehicle which is going even only eight miles an hour. And another thing: If the people walking could be made to cross the streets at corners I do not think there would be so many accidents as now occur; because drivers would be on the lookout for the people at these points. People will cross the street in the middle of the block, where drivers least expect them.

So, what is to be done? Not only is the chauffeur to be arrested for speeding and reckless driving, but the people ought also be made to cross the streets and avenues at the proper point, or do so at their own risk.

EDWARD VAN BAERLE.

New York City.

NEW YORK'S HIGHWAY COMMISSION IS INVESTIGATING

ALBANY, N. Y., April 9.—That the cost of maintaining and repairing good roads in this State during the next year will cost at least $1,500,000, and that the Legislature will look to the owners of automobiles to meet their share of this expense, were among the points that were clearly set forth to-day when the Senate Committee on Internal Affairs gave a hearing on the Allds-Hamn bill, which among other things imposes a substantial registration fee.

Under the provisions of the bill all owners and operators must be registered with the Secretary of State. The registration tax is fixed at $5 for cars weighing 1,500 pounds or less, $10 if the weight be between 1,500 and 2,500 pounds, and an additional $5 for each additional 500 pounds in weight. The bill exempts the automobile from all other taxation.

Charles T. Terry, representing the New York State Automobile Association, took the position that a tax of this character would be discriminatory and invalid. He maintained that the automobile had a right on the highway and that any tax to be equitable must be met by all users of the road.

Senator Allds asked Mr. Terry why the automobile associations had changed their attitude on the question of a tax since last year. Mr. Terry replied that he had no part in the matter.

"The reports of the Massachusetts Highway Commission," Senator Allds said, "show that the automobiles are responsible for 62 per cent. of the wear and tear of roads. Why should not automobiles meet their share of the expense of maintenance?" "The highways are used by every one, and why should not all users pay?" asked Mr. Terry in reply.

Senator Allds said that the method of road construction must be changed on account of the automobile. He said the roads were now going to pieces and that the State must look to the automobile for at least a part of the expense.

"The care of the highway is a governmental expense," said Mr. Terry. "I deny that the automobile wears the roads more than horse-drawn vehicles. The wear is in another way."

Alfred Ely, of the Automobile Club of America, complained of the excessive penalty for the first offense in cases of violation of the speed law. He favored the provision which requires the payment of all penalties and fines into the State treasury.

Speaking in behalf of the farmers, F. N. Godfrey, master of the State Grange, declared that owners of automobiles should pay a special tax, inasmuch as a special highway tax was assessed upon the owners of farm lands.

Giles H. Stilwell, of Syracuse; George C. Diehl, of Buffalo, and O. A. Quayle, of Albany, took the general ground upon which the argument of Mr. Terry was based.

It is estimated that the registration fee as proposed in the Allds-Hamn bill will yield a revenue of $600,000 a year.

It was argued that the wear and tear on good roads by automobiles has been such that the State Highway Commission will not award any more contracts for good roads construction this year, but will devote its efforts to the 500 miles of additional goods roads work now under contract and to the repairing of the 1,800 miles of good roads now constructed.

The Highway Commission has asked the Legislature for an appropriation of $1,500,000 to repair these 1,800 miles of good roads.

The commission is experimenting with an asphalt cement, which is to be utilized in covering all of the stone macadam roads so far constructed.

Meanwhile the State Highway Commission is investigating the question with a view of revolutionizing road construction in this State so as to produce a road which will successfully meet the wear of the automobile.

SITUATION IN NEW JERSEY IS NONE TOO REASSURING

TRENTON, N. J., April 12.—Of course half a loaf is better than no loaf at all, and for that reason one of the stipulations in the Bradley bill that has been most vigorously discussed in and out of the State may be accepted as the best possible result under the circumstances. It would appear that the new tourist's privilege clause, allowing non-residents to use the roads of New Jersey, is to cost $1 and to be available for eight consecutive days, or four periods of two days each. It is explained that the fee of $1 to accompany the application to be made to the department of motor vehicles is not to be considered a license fee, but simply a payment for the clerical trouble involved in the issuing of the temporary license tag.

To many this looks like an unnecessary imposition upon visitors, in view of the fact that none of the other States are likely to have anything similar when the State Legislatures adjourn, and there is a feeling that there will still be some resentment against visiting Jersey.

There are three other main changes included in the so-called Bradley bill. The most important of these is the reduced fee for justices of the peace and witnesses in automobile cases. The second change raises the speed limit from 20 to 25 miles an hour in the open country where the houses are on an average of more than 100 feet apart. The third gives the commissioner of motor vehicles power to grant a temporary license for persons learning.

To clear up the confusion with regard to the Bradley bill, embodying changes in the main automobile law, a conference committee composed of three members of the Senate and three members of the Assembly has been appointed. The trouble with this measure has been caused principally through an amendment introduced by Assemblyman Young, permitting the use of chains on automobile tires while traveling on gravel roads. This amendment is not one that is wanted by the majority of motorists, and had not been asked for by the Associated Automobile Clubs of New Jersey.

In the matter of obtaining lights on all vehicles, that bill after having passed the Assembly now seems to be reposing in the Senate committee on agriculture, of which George W. Gaunt, master of the State Farmers' Grange, is chairman. Apparently there is going to be some difficulty in rescuing this measure from the committee and sending it to its final vote in the Senate.

SITUATION NOW COMPLICATED IN PENNSYLVANIA

PHILADELPHIA, April 12.—Between the "devil" of the Senate and the "deep sea" of the House of Representatives the legislation specially dear to the hearts of automobilists in this city and State will have a hard row to hoe if it is to emerge from the law mill in a shape satisfactory to anybody. The time to do anything worth while is limited, for the Legislature is due to adjourn Thursday.

In the matter of the automobile code the Senate prefers the Grim bill, while the House swears by the Townsend bill. Each branch passed its own bill and sent it to the other. The House amended the Grim bill till it resembled the Townsend measure, and the Senate reciprocated by torturing the latter into a verisimilitude of the Grim bill. The conference committees of the two houses will have to settle the dispute, but it is greatly to

be feared that both measures will fail from lack of time to finally pass either, or that if one is finally decided upon it will be in such shape that all hands will disown it.

The main point at variance is that the Grim measure would license operators, while the Townsend bill would register the cars, and as additional revenue appears to be one of the main objects, the Senators seem to have the Representatives on the hip, for there are approximately twice as many operators as cars in the State. In the matter of the disposition of the fines, there is also a difference of opinion between the two branches. While the House measure as passed finally divides the fines between the State and the townships, according to the class of offense for which they are inflicted, the Senate bill provides that all such money shall be turned into the State treasury.

The cross-State highway bill is also in danger from almost the same combination of circumstances, although in this case there are no twin measures to bother the conferees. The Governor's heart and soul is in the measure, as he desires it as a movement to his administration, and it is quite likely that in the event of its passage in an emasculated form or of the failure of the conferees to agree, some of the pet measures of those responsible therefor will meet with short shrift at his excellency's hands. This is one strong card the automobilists and others interested in the measure are banking on.

CONNECTICUT WILL WELCOME OUTSIDERS.

HARTFORD, CONN., April 12.—The proposed automobile bill drawn up by the committee on roads, rivers, and bridges of the Connecticut State legislature will be presented to the Senate to-morrow. The new bill contains many changes.

Provision is made for the establishment of the office of commissioner of motor vehicles, as already reported. The registration of all cars will expire December 31.

Non-residents, contrary to the prevailing opinion, will not be subjected to any harsh treatment and will be able to use the highways of the State as heretofore. This feature of the bill is commendable.

The cutting out of mufflers is prohibited.

No one less than 16 years of age can operate a motor car under any conditions. Licenses must bear the signature of the party to whom they are issued, and the fees have been increased.

In the matter of speed, various provisions have been looked to, and in city driving ten miles per hour will probably be the maximum. Another provision of the bill will make "joy riding" a hardship. An owner becomes liable for the driver's actions, whose license may be revoked on the second offense.

OHIO LAWMAKER SAYS "MORE MONEY."

COLUMBUS, O., April 12.—Representative Owen J. Evans, of Stark County, in an interview recently given to his home paper, said among other things: "I am in favor of increasing the license on automobiles in Ohio from $5 to $20 for six-cylinder machines. For two-cylinder machines the license should be $10 a year. I expect to incorporate these figures into a bill which will be introduced at the next session of the General Assembly and which I will ask to be enacted into a law. I am also in favor of asking the General Assembly to appropriate $20,000 for each county in Ohio for the improvement of the highways."

Automobile men are of the opinion that a law providing for a State license of $20 and $10 would be declared confiscatory by the Supreme Court and as a result unconstitutional.

NEW YORK STATE MAY LIMIT RECIPROCITY.

ALBANY, N. Y., April 13.—The Robinson bill which to-day passed the Assembly provides in the matter of registration reciprocity recognition only to those non-residents coming from States and territories which grant similar privileges to New York automobilists. Evidently this action is aimed at New Jersey, since Pennsylvania's new law will grant reciprocity.

Harry S. Houpt Company's New Store, New York City.

HOUPT OPENS NEW YORK SALESROOMS.

NEW YORK, April 12.—Herreshoff automobiles now have a home of their own in the metropolitan district, through the opening Saturday of the new showrooms of the Harry S. Houpt Company, Broadway and Sixty-eighth street. For some weeks the cars have been shown at the Hotel Marie Antoinette, during the completion of the new headquarters. Mr. Houpt has one of the most beautiful business places along automobile row, with the interior finished in silver and white, arranged to set off to advantage the latest candidate for light car honors. The Houpt cars will also be handled from this location, when they arrive on the market. Office space is on the second floor.

REMY PLANT IS GROWING RAPIDLY

ANDERSON, IND., April 12.—Three thousand magnetos a week will be the capacity of the Remy Electric Company, when the new brick building, 200 feet by 70 feet, is completed. The structure is to be ready for occupation within thirty days. The new building is but the first of several which are to be completed before the beginning of the 1910 season. Conservative figures, based on the present minimum specified deliveries, estimate the 1909 output of Remy magnetos at 60,000.

The new structure will be of brick, fireproof, with plenty of windows and thoroughly modern in every respect. One of the popular departments which will be enlarged by the factory addition will be the shop for making fittings for attaching Remy magnetos to old-model cars. The Remy plant is now claimed to be the largest in the world devoted exclusively to magnetos.

Interior of the Capacious Houpt Salesrooms.

DISTINGUISHING AN ENGINE BY ITS EXHAUST

PARIS, April 8.—Distinguishing the make of an invisible automobile merely by the sound of its open exhaust proved to be a more difficult task than the contestants had anticipated. There were twenty-two competitors united in a Parisian garage last Sunday morning, and twelve different cars, varying from a one-lunger Sizaire to a lordly 60-horsepower Mercedes, on which the twenty-two had to try their acoustic powers.

Each motor was started up in turn before the competitors and allowed to run for a few seconds with its exhaust pipes removed. The names of all the cars except one had been announced in advance in order to give the intending competitors an opportunity of training. The exception was Charles Y. Knight's sliding-valve engine, built by the Daimler Company, of England; when the time came for it to give the preliminary unmuffled bark the mechanic was still struggling with the exhaust pipe connections, and to save time the competitors were sent behind the heavy curtain without having heard the notes of the exhaust. The engine being quite new to France, it is doubtful if any of the mechanics present were acquainted with its sound.

The first car to be run alongside the heavy curtain behind which the competitors were massed was a four-cylinder Minerva, which proved one of the most difficult to recognize in the whole group. A 1909 four-cylinder Renault followed and for the space of sixty seconds abandoned its pretension to be the most silent car in the world. A Bayard-Clement quickly took its place and added further variety to the exhaust solos. The little Gregoire two-cylinder must have been an easy one for the men behind the curtain, for it was the only twin cylinder under test.

The Sizaire-Naudin one-lunger was equally easy, for there was an unmistakable harshness from its high-speed, high-compression engine. A large Panhard emitted its cheerful healthy hum, contrasting strongly with the harsher and sharper bark of the 1909 Mercedes which immediately followed. The little Lion-Peugeot one-lunger, too, made a strong contrast with the Sizaire-Naudin, although the two were almost identical in power and bore of cylinder. The Delage diminutive four-cylinder had more of a hum than a roar, and should not have deceived any who had previously listened to its sound.

The Knight sliding-valve engine, that nobody had heard before, and that was looked upon as the stumbling block of the competition, proved to have such a soft muffled sound, even with the exhaust box removed, that nobody could be deceived. A four-cylinder Gregoire added its contribution to the solos, and the last note to be heard was the strident cry of a four-cylinder Mors.

The competition was rendered the more difficult from the fact that the exhaust piping was not entirely removed in all cases. This was left to the appreciation of the mechanics, and where it was more convenient to do so the piping was removed at the engine itself; in other cases disconnection was made where the tubing entered the exhaust box; in a few cases an exhaust cutout was brought into use. Obviously the sound was modified according to whether the exhaust passed directly into the air or first traveled along several feet of piping.

After examination of the papers it was found that the winner was Victor Gros, a nineteen-year-old mechanic, who had correctly named eight of the twelve machines. M. Leguen, a veteran mechanic, really paired with his young rival, giving eight out of twelve, but as he had not attempted to designate the remaining four, he was put into second position. Drouet and Poupelin, both young mechanics, each correctly named six cars out of a possible twelve, and M. Fontaine, a young soldier in an engineer regiment, shared fourth prize with M. Docrine, each having five correct answers out of twelve. Five others gave three correct answers, while the rest could do no better than two, one and nothing.

The winner failed on Minerva, Delage four-cylinder, Mors, and Gregoire four cylinder; the second man found his stumbling blocks in Minerva, Gregoire, Mors and Renault.

FRENCH SALON LOOKS IMPROBABLE NEXT WINTER

PARIS, April 8.—Of the four associations jointly responsible for the Paris Salon the two most important are so stoutly opposed to the event that its abolition for 1909 is practically certain. The executive committee, presided over by Gustave Rives, and responsible for the organization of the fashionable exhibition in the Grand Palais, is recruited from the Automobile Club of France, the Chambre Syndicale de l'Automobile, the Chambre Syndicale du Cycle et de l'Automobile, and the Syndicat des Fabricants de Cycles. Profits arising from the Salon are carried to a reserve fund in the name of the four interested parties.

The Automobile Club of France, only a certain proportion of whose members are actively engaged in the industry, believes that the show should be continued, and has voted accordingly. In this, of course, they are only looking to their own interests, the Salon always having been a source of profit. The comparatively unimportant Syndicat des Fabricants de Cycles, not having to bear much of the expense of costly exhibitions, has also voted in favor of the retention of the Paris Salon.

The Chambre Syndicale du Cycle et de l'Automobile, under the presidency of M. Darracq, has declared by a large majority against the holding of a show in 1909. The Chambre Syndicale de l'Automobile was capable of deciding either for or against the show, and particular importance therefore attached to the meeting of its committee this week when the Paris Salon came up for consideration. The Marquis de Dion, president of the Chambre Syndicale, fought stoutly for the retention of the annual show on the grounds that it was necessary for the complete development of the industry. The members of his committee, however, were not all of the same opinion, and after a wordy battle lasting two hours, the vote was 11 for and 10 against, with 2 blank.

The anti-show vote has still to be ratified by the full assembly of the Chambre Syndicale, and if this is done it is difficult to understand how the Paris Salon can be held. The Marquis de Dion declares that if the full meeting of his association votes in favor of the abolition of the show he will resign his position of president and work with the Automobile Club of France for the holding of the show. A salon, however, in which none of the leading firms will take part is not worthy the name of national.

MICHELIN GIVES BRITISH AERO PRIZE.

LONDON, April 3.—The Michelin prize has done so much to help on the progress of aviation in France that great interest has been evinced at the news that the tire firm has offered a British Michelin prize to the Aero Club of the United Kingdom. The prize takes the form of a $2,500 trophy, and a further sum of $2,500 will be awarded to winners during the next five years.

The contest is limited to British aviators employing British-built machines, and, as with the French prize, the winner will be the one who flies the greatest distance over a certain specified course. The minimum distance for each year must be double that of the preceding year till the 250-mile mark has been reached. Should the prize not be gained during any one year, the money endowment would be added to that of the next year.

How La Turbie Is Conquered These Days

By W. F. Bradley

PARIS, April 5.—The past week saw the revival of the once famous hill-climbing contest of La Turbie, the hill near Nice in the south of France. The events of the meeting, which lasted a week from March 28, were aided by almost perfect weather and plenty of sunshine. The course selected was 6 kilos 400 meters long (3.974 miles), with a practically perfect surface, but a few bad turns. At these some of the less fortunate contestants turned turtle, but no one was hurt. This was indeed fortunate, considering the circumstances under which the races were formerly abandoned as well as for the drivers themselves, taking into account the speed at which they were traveling and the nature of the curves. Among the cars which overturned, but fortunately were not damaged, were a Mors, Berliet and Darracq, with such skillful drivers "up" as Hallut, Whitlock and Ragusa.

The two things that stand out most prominently in the result are the performances of Sizaire and Bayard-Clement. The latter won a double victory, taking first place in each of two in the total of nine classes, which brought corresponding honor because no other make scored in more than one contest. These classes were the two-cylinder, any bore or stroke, and the four-cylinder, limited to 75-85 mm. (2.95-3.35").

This was completely overshadowed by the victory of the cars bearing the name of Sizaire & Naudin. These little "one-lungers" not only won the monocylinder event, but took second, third, fourth and fifth in the same. Not content with this, Sizaire, who drove the winner, made the second fastest time of the week, being beaten only by the Opel, with a four-cylinder machine of 115 mm. (4.53") bore, the limit in its class. This means, also, that Sizaire not only hopelessly outclassed all other single-cylinder cars, but went over the severe course in less time than all of the two-cylinders, all fours except Opel, and all sixes. It was a sweeping victory for the car with a single lung.

Of equal importance with the two sterling performers just mentioned was the new Daimler car from the Unterturkheim works and fitted with the Knight engine which has caused such a furore in the past few months. This marked the first appearance of the Knight-Daimler engine in competition, and its performance was as a consequence watched very closely, more so than any other car present. This class was the fifth and for engines of any bore greater than 96 mm. and less than 105 mm. The limits just let in the model now rated at and sold as a 22-horsepower machine. The car and engine behaved very well and won second place in the division. The time made was 7 min. 29 3-5 sec., which brought it rather close to the winning La Buire.

The complete summary of the hill climbing results follows:

Class 1—(Single cylinders) George Sizaire (Sizaire & Naudin), time 6 mins., 12 2-5 secs.

Class 2—(Two cylinders) Albert Roux (Bayard-Clement), time 13 mins., 57 4-5 secs.

Class 3—(Four cylinders of 75-85 mm. bore) Louis Sharp (Bayard-Clement), time 8 mins., 7 2-5 secs.

Class 4—(Four cylinders of 86-95 mm. bore) Paul de Latzger (Laurin-Klement), time 6 mins., 42 1-5 secs.

Class 5—(Fours of 96-105 mm. bore) Paul Scoffier (La Buire), time 7 mins., 10 2-5 secs.

Class 6—(Fours of 106-115 mm. bore) Lindpaintner (Opel), time 6 mins., 0 1-5 secs.

Class 7—(Fours of 116-130 mm. bore) Juge (Pilain), time 7 mins., 38 4-5 secs.

Class 8—(Six cylinders) Schneider (Rochet-Schneider). time 7 mins., 21 secs.

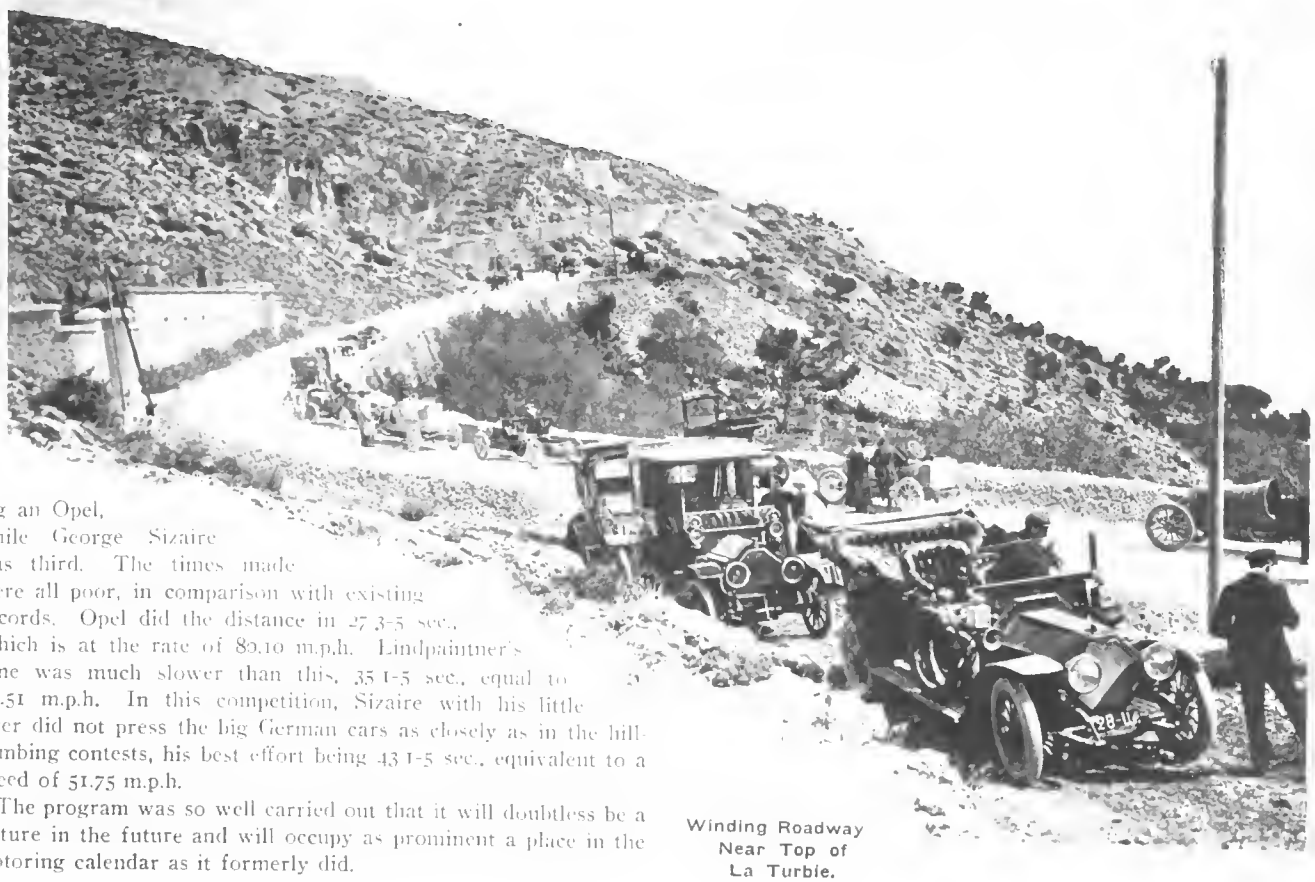
Class 9—(Voiturettes, Grand Prix type) Chevillot (FEN), time 10 mins., 36 1-5 secs.

The former course differed from the one used mainly in length, the greater distance of nearly 16 kilos requiring the use of the present course and some distance on each end of it. The races have aroused all of the old enthusiasm which this week of contests always brought out and which continued up to the year of misfortune, when Zabriskie was killed and the meet abandoned.

Three days previous to the hill climbing the flying kilometer trials were held, with results very similar. The fastest time was made by an Opel, in class 7; the next by Lindpaintner, also driving an Opel, while George Sizaire was third. The times made were all poor, in comparison with existing records. Opel did the distance in 27 3-5 sec., which is at the rate of 89.10 m.p.h. Lindpaintner's time was much slower than this, 35 1-5 sec., equal to 63.51 m.p.h. In this competition, Sizaire with his little flyer did not press the big German cars as closely as in the hill-climbing contests, his best effort being 43 1-5 sec., equivalent to a speed of 51.75 m.p.h.

The program was so well carried out that it will doubtless be a fixture in the future and will occupy as prominent a place in the motoring calendar as it formerly did.

Lindpaintner and His Winning Opel on Course.



Winding Roadway Near Top of La Turbie.

Problems of Aerial Flight Are Being Solved Rapidly

Santos-Dumont Getting Ready for His Monoplane Flights at St. Cyr, near Paris.

PARIS, April 9.—To-day M. Santos-Dumont made a successful flight with his new monoplane, the *Mademoiselle,* at St. Cyr, near this city, covering a mile and a half with great ease. Santos-Dumont has consistently adhered to the idea that a monoplane could be constructed that would prove practical, and his triumph over the forces of nature on this occasion gives great satisfaction to Europe's pioneer aeronautical engineer and his many friends.

His monoplane, which holds the record for lightness and diminutive size, weighs but 330 pounds, and is simplicity itself in its construction. The power plant, which is a Duthiel-Chalmers, two-cylinder opposed air-cooled engine, is located above the main bearing surface of the two main wings, and in the slight angle formed by them. The aviator's seat is located under the motor and the wings, and is a piece of canvas but five or six inches above the ground.

Farman Is Busy on Aeroplane of Special Design.

PARIS, April 7.—Dissatisfied with the little progress made during the past year with the flying machines furnished him by the builders, Henry Farman has broken away from the group and is now at the head of his own aeroplane building factory. The change affects not only the flying machine, but the engine also, Farman having decided that the eight-cylinder water-cooled engine is not good enough for his work and has ordered a seven-cylinder air-cooled rotary engine recently produced by the Gnome Company.

Duthiel-Chalmers Motor, Used by Santos-Dumont.

The engine has its seven cylinders radiating from a circular crankcase through which passes a stationary, hollow one-throw crankshaft. The cylinders are of nickel steel, and when first constructed had radiating flanges of equal depth descending down to near the end of the stroke. Shop tests showed, however, that 15 pounds of metal per engine could be saved by gradually lessening the depth of the fins as they neared the base of the cylinder. Method of attachment to the crankcase is by means of a locking ring fitting over the base of the cylinder within the case. There is not a single projecting bolt on the face of the crankcase to receive the cylinders.

There is one main connecting rod with integral big end, and to this are attached the six other connecting rods in practically the same way as the upper end of the connecting rod is attached to its piston in standard automobile practice. The main connecting rod is fitted to the crankshaft with ball bearings. Exhaust valves are in the cylinder head, and are operated by balanced rocker arms. The inlets are in the piston head, and are consequently automatic. The firing charge arrives through an intake pipe passing through the hollow crankshaft, then passes behind the piston through the valve in its head, the carbureter, of an ordinary type, being stationary while the rest of the engine, including the magneto, is revolving.

On the Farman aeroplane the propeller, a wooden one, constructed by Chauviere, is mounted on the rear of the crankcase. The forward face of the crankcase, on which are mounted the timing gears, is covered by a torpedo-shaped aluminum casing to decrease the wind resistance. The engine develops 50 horsepower at 1,200 revolutions a minute, and they have been able to prove during the shop tests, will throttle down as low as 250 revolutions a minute without a misfire. The control is entirely on the throttle, the sparking point being fixed. The strong draught caused by the revolutions of the engine keeps the cylinders wonderfully cool. Even after two hours' steady running on the testing block the steel cylinders are hardly discolored and it is possible to touch them with the naked hand. Naturally the conditions in the open air will be still more advantageous.

Gnome 7-Cylinder Motor, Used by Farman.

Lubrication is taken care of by centrifugal force. An ordinary type of oiler is carried in some convenient position on the aeroplane, its supply of lubricant being delivered to the main bearings by a single pipe passing through the hollow crankshaft.

Henry Farman declares that in addition to the two machines that he is now building for his own use he has orders on hand for several aeroplanes of a similar type, and is prepared to turn out flying machines with a guaranteed ability to fly. It is with these machines that he intends to compete in the most important European [illegible] this year.

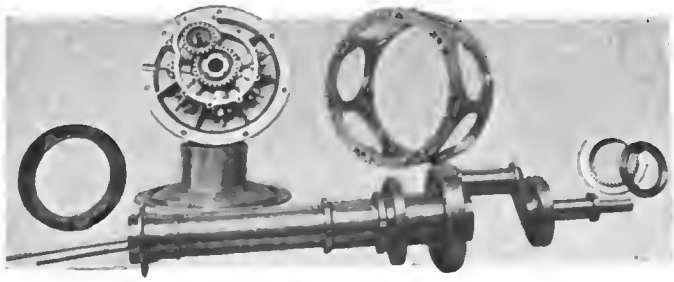
ENGINES AT BRITISH AERO SHOW.

LONDON, April 3.—At the Aeroplane Show, which has now closed its doors after a successful run, special interest was attached to the engine section, for here there was not that unfinished and doubtful air which seemed to be characteristic of the aeroplane exhibits themselves.

The British exhibits were not many in number, for several of the leading manufacturers who are known to be experimenting have, naturally enough, no desire to seek publicity for their efforts at present, but the engines that were on view showed a commendable originality of design and good workmanship.

Wolseley.—The Wolseley Motor Company exhibited two engines which were excellent representatives of their class. The first was built for aeroplane work and has eight V cylinders set at 90 degrees. The cylinders are 90 mm. bore by 125 mm. stroke, and 60 horsepower is developed at 1,350 revolutions per minute. The water jackets are of sheet aluminum and are attached to the cast steel cylinders by a row of screws. The induction and water pipes are also of aluminum. Forced lubrication to all bearings is effected by a gear pump. This engine, weighing five pounds per horsepower, has been constructed for a British monoplane, which is almost ready for its trials.

A second engine on this stand is designed for a dirigible balloon. The eight vertical cylinders of 165 mm. bore by 178



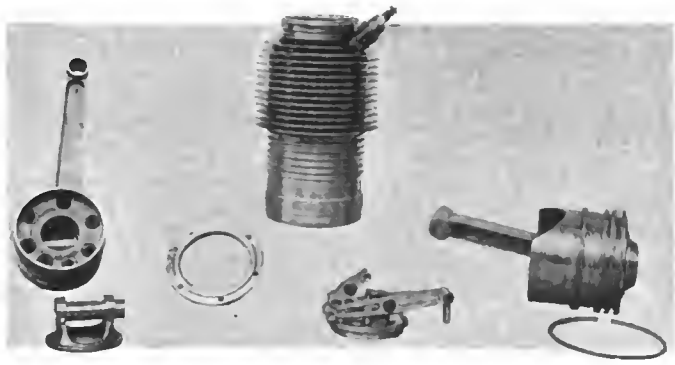
Crankshaft and Details of Gnome 7-Cylinder Motor.

mm. stroke develop 200 horsepower at 1,000 revolutions per minute. The jacket and pipes are of aluminum.

Aster.—Of the several other firms who showed engines with vertical cylinders, the Aster Company attracted special attention with the Green engine. These engines, which have four vertical cylinders for the lower powered models and eight V cylinders for the 80 horsepower type, work on the standard four-cycle principle, but the constructive details are quite original. The cylinders are separate steel castings machined all over, with cylindrical valve chambers projecting from the head. The water jackets are pressed in one piece from sheet copper and are open at the bottom end and closed at the top. When in place the bottom end slides over a rubber ring carried in a groove in the cylinder casting, thus making a water-tight joint and allowing for expansion. Above the cylinder head, the jacket presses on collars turned on the cylindrical valve seatings and are finally held in place by the aluminum domed valve covers.

A single overhead camshaft operates the valves through rock levers. These levers are all enclosed in an oil-tight aluminum casing and the whole arrangement can be hinged back out of the way when a valve is to be removed. The cylinder holding-down bolts also hold the five substantial crankshaft bearings.

New.—The New Engine Company is the first well-known British firm to adopt the two-cycle engine, and its production seems quite an advance on existing types. The 40 horsepower model has four steel cylinders, 4 1-2-inch bore by 4-inch stroke. The exhaust ports open when the piston has traveled half way down on its stroke, the burnt gases discharging direct into a silencer. A little further in the stroke the inlet ports are uncovered and a blast of air is blown in, driving out the remainder of the products of combustion. The air blast remains in operation till the end of the stroke and is then diverted by a rotary valve into an aluminum jacket surrounding the cylinders, replacing the usual water jacket. At the commencement of the

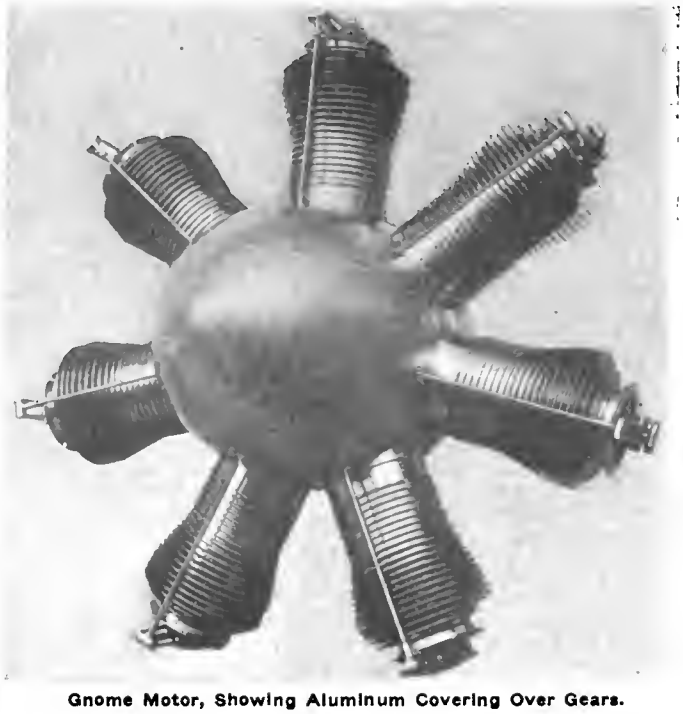


Cylinder and Piston of Gnome Motor, Dissembled.

upward stroke a charge of very rich mixture is admitted to the cylinder through the rotary valve and the resultant explosive mixture is compressed and fired in the usual way.

International.—The International rotary motor is another British production that works on novel lines. The two cylinders are opposed, and with each is cast half of the crankcase. The propeller shaft is attached to a ring bolted to the cylinder castings, while the crankshaft, with its two cranks at 180 degrees, remains stationary. The gas is drawn through a non-return valve into the crank chamber, and as the pistons come together the gas is forced into one cylinder or the other alternately through an external pipe. The inlet and exhaust valves are mechanically operated and no springs are used, the valves closing themselves quickly by centrifugal force. The ignition is by Bosch magneto and the current is conducted to the plugs through two spring plungers working on slip rings.

Continental Makes.—All the best known Continental engines that were to be seen at the Paris Show were staged at Olympia, and in many cases improvements have been effected during the interval. The R. E. P. engine is now made in a 10-cylinder type, rated at 40-50 horsepower, in addition to the five and seven-cylinder models previously supplied. In all these engines the cylinders are set fanwise in two rows, the rear cylinders covering the spaces between those in the front row. The 50-horsepower Gnome has seven radial air-cooled cylinders, and these revolve around the stationary crankshaft. Other engines are the Gobron-Brillié, which has four cylinders arranged like an X, and the eight-cylinder V models of Renault and E. N. V., the former air cooled and the latter water cooled.



Gnome Motor, Showing Aluminum Covering Over Gears.

MAKING THE AUTO PAY FOR THE ROAD.

Desire is plainly evident in not a few State legislatures now in session to saddle upon the automobile owners a greater part of the cost of the upkeep of the highways. If the matter were left to a popular vote of all owners of motor-driven vehicles, it is not improbable that the decision would be favorable to a graduated annual tax, provided all other users of the highway were asked to pay their just proportion.

Once upon a time the New York *Times*, now progressive, suffered from an acute attack of automobile antagonism. But a change has come in its ideas—many other daily newspapers have had similar revisions of opinion—and we reprint concerning a proposed New York State law the following editorial which it printed it under the head of "A Motor Car Tax":

A graduated tax levied according to the weight of the machines is proposed in the Aldis-Hamm bill, which prescribes rules to register, identify, and regulate motor vehicles and their operators on the public highways. The purpose of the tax is "to raise nearly enough money to repair the damage they do to the good roads." It will cost $1,500,000 to repair the 1,800 miles of "good roads" already built in the new State system which have been raveled by autos.

For two reasons we think the proposed tax is unjust. If it is to be imposed, proportionate taxes should be applied to other vehicles using State roads. The Constitution requires this. Secondly, it is not the fault of the automobilists or of their machines that the roads are in their present plight, but the fault of the road builders. They have stupidly persisted in dressing their surfaces with a finely comminuted material which they well knew must be displaced and thrown to the rear by the so-called suction of rubber tires.

It is self-evident that the wearing surfaces of roads should be suited to the vehicles that traverse them. The newly created State Highway Commission has wisely decided not to award contracts for further construction of "trunk-line boulevards" until some one of the special surfacings of bitumen or oil with asphaltic bases shall have been adopted. Meanwhile, it would be manifestly unfair to tax motor cars or other vehicles for blunders of highway builders.

It is a fact daily becoming more apparent that the present highway is not suited to the increased demands made upon it, caused principally by the multiplied mileage of the motor-driven vehicle, and a remedy must and will be found by those entrusted with our roads building. It is far from probable that all macadam roads now being constructed are given the same careful building as was received by their predecessors. Only recently did some of the discerning politicians become aware of the fact that the people as a whole want good roads, and that in their building there might be opportunities of profit to those directing the expenditure of the public money. Roads have worn out much faster in some sections than in others, with indications that supervision might have been faulty and negligent.

But the roads question is one that is vital to a commonwealth as a whole, and, realizing such to be the case, it is predicted that the problem will be solved ultimately in a satisfactory manner.

* * *

CLASSIFICATION WILL CLEAR ATMOSPHERE.

With the definite and comprehensive classification of cars adopted by the rules committee of the Manufacturers' Contest Association, and by it recommended to the Contest Board of the A. A. A., it begins to be apparent to the lay mind that a much mixed situation is gradually being improved. Only time will prove the wisdom of the rules, but clarification on the subject of contests is an obvious necessity which has called for attention.

There have been contests and contests, each different from the previous one. Price, weight, piston displacement, various curious formulas, and all sorts of classes existed, and, upon application, were sanctioned. The result was that it was hard to decide whether a winning car really showed merit or not. The car that won in one unique class would be hopelessly left behind in the next contest with some other unusual arrangement.

To have a real comparison of the performance of two different cars, it is first necessary to have a uniform series of performances under standardized conditions. This heretofore has not been available because of haphazard classes, varying at every opportunity. Now that the manufacturers, who are the ones vitally interested in a real comparison, have stepped in, and, through the medium of their representatives, placed themselves on record as in favor of standardized tests, and deduced a set of acceptable standards, this matter has been reduced to its understandable terms.

In the future, acting under the new standards, the results obtained in the East will be comparable with those which take place in the West. The races everywhere being upon one basis, it will be possible at the end of the year to deduce the best American car in any desired class. Except that some one prominent maker absents his product, this yearly summary will be beyond question trustworthy. It begins to look as if the final result will have a very great value to all concerned.

N. A. A. M. EXECUTIVE COMMITTEE BELIEVES IN M. C. A.

PLAINLY expressed and subject to no misinterpretation was the pronounced manner in which the executive committee of the National Association of Automobile Manufacturers at the regular monthly meeting, held April 7, in New York City, placed itself upon record as approving the alliance between the Manufacturers' Contest Association and the American Automobile Association. The session was held as usual at the association's headquarters, No. 7 East Forty-second street, and the full text of the resolution is herewith given:

Whereas, The interests of automobile manufacturers in contests of all descriptions are well represented by the Manufacturers' Contest Association, to membership in which all manufacturers are eligible and to which a large number of manufacturers have already applied for membership; and

Whereas, A formal alliance has been entered into between the Manufacturers' Contest Association and the American Automobile Association, one of the conditions of which alliance provides for an advisory committee representing the manufacturers and appointed by the principal trade organizations, which committee takes an active part in the deliberations of the contest board of the American Automobile Association; and

Whereas, The interests of the trade demand not only the maintenance of such an association but active participation by it in matters relating to contests of all descriptions; be it

Resolved, That members of the National Association of Automobile Manufacturers, Inc., be and are hereby respectfully urged to apply for membership, to take an active interest in and to loyally support the Manufacturers' Contest Association and its rules; and be it further

Resolved, That the Manufacturers' Contest Association will act in accordance with the desires of this association by giving full publicity to its regulations and decisions, and by taking such definite action as will disbar from events sanctioned by the American Automobile Association all persons or organizations who or which take part in, or in any other way support any event not so sanctioned.

W. E. Metzger, the first vice-president, presided in the absence of President S. D. Waldon, who was unable to attend. These were the other members of the committee present: S. T. Davis, Jr., Locomobile Company of America; Windsor T. White, the White Company; Thomas Henderson, Winton Motor Carriage Company; William R. Innis, Studebaker Automobile Company; C. C. Hildebrand, Stevens-Duryea Company; H. O. Smith, Premier Motor Manufacturing Company; Albert L. Pope, Pope Manufacturing Company; Benjamin Briscoe, Maxwell-Briscoe Motor Company; L. H. Kittredge, Peerless Motor Car Company; J. W. Gilson, Mitchell Motor Car Company, and C. G. Stoddard, Dayton Motor Car Company.

The Rapid Motor Vehicle Company, of Pontiac, Mich., was elected to association membership.

Atlanta Will Have a National Show.

Preceding the executive committee meeting there was a session in the morning of the show committee, during which there appeared a notable delegation from Atlanta to ask that that enterprising Southern city be placed in the very limited national show circuit, which now includes only New York and Chicago. It was the contention of the delegation from the "Gate City of the South" that a national show would be an excellent investment for the industry, and these were the men who urged Atlanta's claims: Clark Howell, managing editor of the Atlanta *Constitution;* John L. Cohen, S. C. Dobbs, of the Chamber of Commerce; Charles R. Ryan, J. T. Fitten, E. M. Hansom, and E. W. Gans.

The show committee was so favorably impressed with the arguments presented that it voted to recommend to the executive committee that Atlanta have a show conducted directly under N.A.A.M. auspices. At the executive committee's meeting the matter received thorough attention, with the result that S. A. Miles, the general manager, was empowered to conduct final negotiations with the proper parties in Atlanta, to which city Mr. Miles will subsequently pay a visit, perhaps accompanied by Alfred Reeves, of the American Motor Car Manufacturers' Association.

A. M. C. M. A. SELECTS SHOW AND OTHER COMMITTEES

R. E. OLDS will be the chairman of the new show committee of the A. M. C. A., the Committee of Management of which held its monthly meeting at 505 Fifth avenue, April 8. The other members of the committee will be S. H. Mora and Benjamin Briscoe, with Alfred Reeves as general manager. The association will conduct its tenth international automobile show at Grand Central Palace, New York, on dates yet to be named.

The formation of the Manufacturer's Contest Association, for the purpose of taking a concrete interest in racing and contest matters, was unanimously approved, and a resolution was adopted recommending that all members of the A. M. C. M. A. join and support the new organization, which has an agreement with the Automobile Association of America regarding contest matters. It was decided further that the members should be asked to take the matter up with their dealers throughout the country that the actions of the M. C. A. may be fully supported.

A large amount of routine business was transacted, the meeting being in session until late in the day. In attendance at the meeting were: H. O. Smith (Premier Motor Manufacturing Company), chairman; C. G. Stoddard (Dayton Motor Car Company); S. H. Mora (Mora Motor Car Company); G. Vernon Rogers (Mitchell Motor Car Company); W. H. VanDerVoort (Moline Automobile Company); Benjamin Briscoe (Maxwell-Briscoe Motor Company); R. E. Olds (Reo Motor Car Company); Charles Lewis (Jackson Automobile Company; C. C. Hanch (Nordyke & Marmon Company); and Alfred Reeves, general manager. These committees for 1909 have been announced by Chairman Smith:

Show Committee.—R. E. Olds, Reo Motor Car Co., chairman; S. H. Mora, Mora Motor Car Co.; Benjamin Briscoe, Maxwell-Briscoe Motor Co.

Tours and Races.—W. H. Van Der Voort, Moline Automobile Co., chairman; A. C. Newby, National Motor Vehicle Co.; V. A. Longaker, American Motor Car Co.; Walter C. Marmon, Nordyke & Marmon Co.

Good Roads.—Charles Lewis, Jackson Automobile Co., chairman; James Couzens, Ford Motor Co.; R. M. Owen, Reo Motor Car Co.; H. B. Krenning, Dorris Motor Car Co.

Legislation.—C. G. Stoddard, Dayton Motor Car Co., chairman; A. C. Newby, National Motor Vehicle Co.; R. A. Palmer, Carter Car Co.; R. E. Graham, Acme Motor Car Co.; Walter E. Hildredth, Hoisman Automobile Co.; Walter S. Austin, Austin Automobile Co.

Finance.—James Couzens, Ford Motor Co., chairman; W. G. Morse, Atlas Motor Car Co.; J. B. Bartholomew, The Bartholomew Co.

Membership.—S. H. Mora, Mora Motor Car Co., chairman; Morris Grabowsky, Rapid Motor Vehicle Co.; W. H. Van Der Voort, Moline Automobile Co.

Advertising and Publicity.—J. N. Willys, Overland Auto Co., chairman; G. B. Louderback, Buckeye Mfg. Co.; Theo. P. Bailey, St. Louis Car Co.; Leon M. Bradley, New York office; Charles E. Duryea, New York office.

Standardization and Technical.—Geo. A. Weidely, Premier Motor Mfg. Co., chairman; John D. Maxwell, Maxwell-Briscoe Motor Co.; Henry Ford, Ford Motor Co.; Max H. Grabowsky, Grabowsky Power Wagon Co.

Freight and Transportation.—G. V. Rogers, Mitchell Motor Car Co., chairman; Harry Knox, Atlas Motor Car Co.; H. W. Mack, Mack Bros. Motor Car Co.; R. Harry Croninger, Pennsylvania Auto-Motor Co.; J. N. Willys, Overland Automobile Co. (In conjunction with traffic department of N. A. A. M.)

Tires.—W. S. Marmon, Nordyke & Marmon Co., chairman; James Couzens, Ford Motor Co.; Frank Briscoe, Brush Runabout Co.; O. Stevenson, York Motor Co.; S. H. Mora, Mora Motor Car Co.

Agencies.—W. H. Van Der Voort, Moline Automobile Co., chairman; A. R. Welch, Welch Motor Car Co.; H. R. Mallow, De Luxe Motor Car Co.; Frank L. Pierce, Gaeth Automobile Co.; H. B. Larzelere, Chadwick Engineering Works.

M. C. A. PRESIDENT EXPLAINS ITS WHYFORE AND PLANS

By BENJAMIN BRISCOE, President Manufacturers' Contest Association.

BELIEVING that automobile contests can be encouraged and improved by support of a concrete nature, such as an organized body of automobile manufacturers can supply, the motor car makers have organized what is known as the Manufacturers' Contest Association, the work of which will undoubtedly be of great importance to the pastime and industry, and the plans of which are naturally of considerable interest at this time.

It is agreed that the automobile makers who supply the sinews of war in speed and other contests should have some voice in the rule-making, but not in the enforcement of rules. There can be no argument as the maker's knowledge of what rules would be best to bring out the merits or demerits of cars for the final edfiication of the geenral public, but, on the other hand, there can be no argument but that the actual government of contests, and the enforcement of the rules generally, should be in the hands of men without trade affiliations of any sort. Undoubtedly in the suggestions which the makers may offer for rules there will be many that, for some reason or other, are not acceptable to the national governing body, and in many cases the final interpretation of rules as made by the governing body of racing may not meet with approval of all makers. It is the difference of opinion which makes contests interesting.

In accordance with the agreement which the American Automobile Association and the Automobile Club of America have, the Manufacturers' Contest Association recognizes the A. A. A. as the national governing body and the A. C. A. in all events of an international character. There is no desire on the part of the M. C. A. to act other than in an advisory capacity, which it will do, always having in mind the best interests of the industry.

There is no denying the fact that there was much to be criticized in the manner of conducting automobile racing in the past. It was said by some of those interested in the sport, however, that the support of all the manufacturers was needed to better conditions, and this is now made possible by the new organization, which enters the field without a thought of what has taken place in the past, but considering only the present and the future.

That the new association can bring about many desirable improvements admits of no argument. It will work for uniform rules, better classifications for racing cars, uniform fees and sanctions, and generally encourage automobile clubs and trade associations to promote contests. It will not hesitate to make recommendations whenever it deems that such recommendations are in order, and in every other way it will work to advance the best interests of motoring, from a competitive and from a business point of view.

At the same timc it must always be remembered that the M. C. A. can encourage only those contests that are promoted with due respect for the State laws and the rights of others on the highways. To do otherwise would bring it into disrepute with the lawmakers of the various States and would eventually bring on the heads of motorists generally unfair laws that would make their pastime anything but pleasant. The manufacturers from time to time are represented and have to appear themselves before the various legislative bodies and to do other than consider carefully all phases of open competition on the road would weaken their position in legislative work, which it is agreed, is of more importance than any other department of motoring.

MOSLER'S PURCHASE OF SPARK PLUG PATENTS

MUCH interest has been aroused in the automobile world by the announcement of the sale of the basic spark plug patents by the Association Patents Company, the patent-holding end of the Association of Licensed Automobile Manufacturers, to A. R. Mosler & Company, of New York City. The two patents in question are known as the Canfield and Mueller, and are numbered 612,701 and 582,540, respectively, in the Patent Office. In notifying the trade and public of their purchase of these patents, A. R. Mosler & Company set forth their reasons for acquiring them as follows:

For several years these patents have been the cause of considerable anxiety on our part, because we believe that if any suit had been brought against us upon them and particularly the Canfield patents, we would have been unable to successfully defend such a suit.

The prior art bearing upon these patents was carefully investigated and considered by our counsel and we were advised by him that it was highly advisable for us to acquire these patents and particularly the Canfield patent, which, in the opinion of our counsel, is not anticipated by anything in the prior art and is undoubtedly valid and quite broad in scope.

All manufacturers of spark plugs in this county recognize the value and importance of manufacturing spark plugs each provided with a deep chamber or recess around the electrode for the purpose of preventing an injurious accumulation of soot or other foul matter on the insulation of the electrode. Indeed, all of the well-known spark plugs now upon the market in this country are each constructed with a deep chamber or recess around the electrode and consequently are within the claims of the Canfield patent. This Canfield patent contains two claims which are as follows:

(1.) In a gas, oil or vapor engine igniter or sparker a recess or counterbore around the electrode or electrodes and above its or their sparking-points when said electrodes are used vertically, for the purpose of preventing an injurious accumulation of the products of combustion or other foul matter on the insulation of said electrodes, substantially as and for the purpose set forth.

(2.) In a gas, oil or vapor engine igniter or sparker a recess or counterbore of such size and depth as to prevent the explosive mixture used in the cylinder from circulating into said counterbore or recess far enough to come in contact with its deepest part around the electrode or electrodes at or near the point where said electrode or electrodes leave the insulator to enter the cylinder or firing-chamber, for the purpose of preventing an injurious accumulation of the products of combustion or other foul matter on the insulation of said electrodes, substantially as and for the purpose set forth.

The following mentioned members of Association of Licensed Automobile Manufacturers have been licensed under these patents:

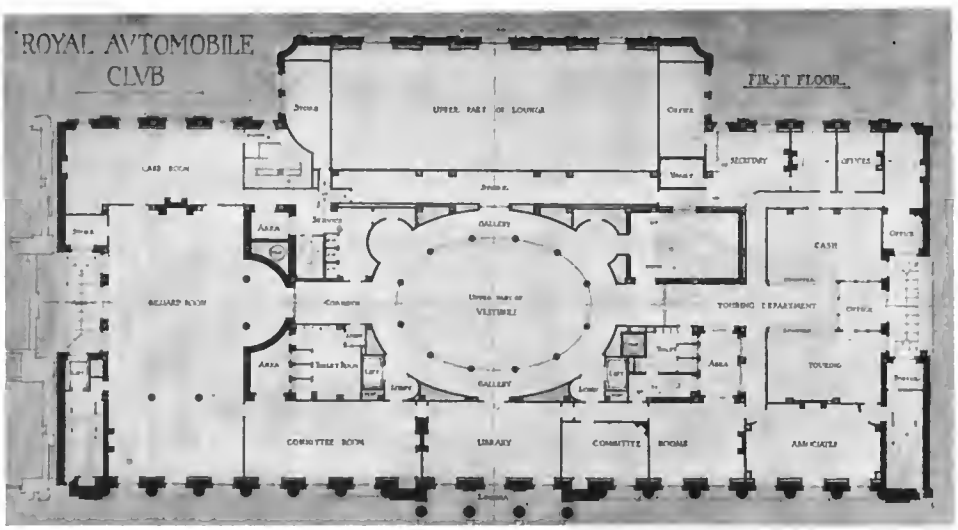
Apperson Bros. Automobile Company, Kokomo, Ind.; Autocar Company, Ardmore, Pa.; Chalmers-Detroit Motor Company, Detroit, Mich.; Cadillac Motor Car Company, Detroit, Mich.; Corbin Motor Vehicle Corporation, New Britain, Conn.; Everitt-Metzger-Flanders Company, Detroit, Mich.; Electric Vehicle Company, Hartford, Conn.; Elmore Manufacturing Company, Clyde, Ohio; H. H. Franklin Manufacturing Company, Syracuse, N. Y.; Hewitt Motor Company, New York City, N. Y.; Knox Automobile Company, Springfield, Mass.; Locomobile Company of America, Bridgeport, Conn.; Lozier Motor Company, New York City, N. Y.; Matheson Motor Car Company, Wilkes-Barre, Pa.; Packard Motor Car Company, Detroit, Mich.; Peerless Motor Car Company, Cleveland, Ohio; Pierce-Arrow Motor Car Company, Buffalo, N. Y.; Pope Manufacturing Company, Hartford, Conn.; Royal Tourist Car Company, Cleveland, Ohio; Alden Sampson 2d, Pittsfield, Mass.; Selden Motor Vehicle Company, Rochester, N. Y.; F. B. Stearns Company, Cleveland, Ohio; Stevens-Duryea Company, Chicopee Falls, Mass.; E. R. Thomas Motor Company, Buffalo, N. Y.; Toledo Motor Company, Toledo, Ohio; Winton Motor Carriage Company, Cleveland, Ohio.

"F. A. L." REPLACES "CAR WITHOUT A NAME."

CHICAGO, April 12.—Announced as "the car without a name," the four-cylinder touring car which has made its début in this city during the past week will hereafter be called the "F. A. L." The initials are those of the three men who are most interested in its production and sale: T. S. Fauntleroy, president; H. R. Averill, general sales manager, and E. H. Lowe, general manager and secretary. Mr. Averill, who has resigned as sales manager of the York Motor Car Company, has stated that the new cars will be entered in all contests in its class, including the light car race near here, the Savannah light car race, the Quaker City Motor Club Founders' Week race, and all endurance contests. It will be seen in the Glidden tour, the Motor Club of Harrisburg run and other events of importance.

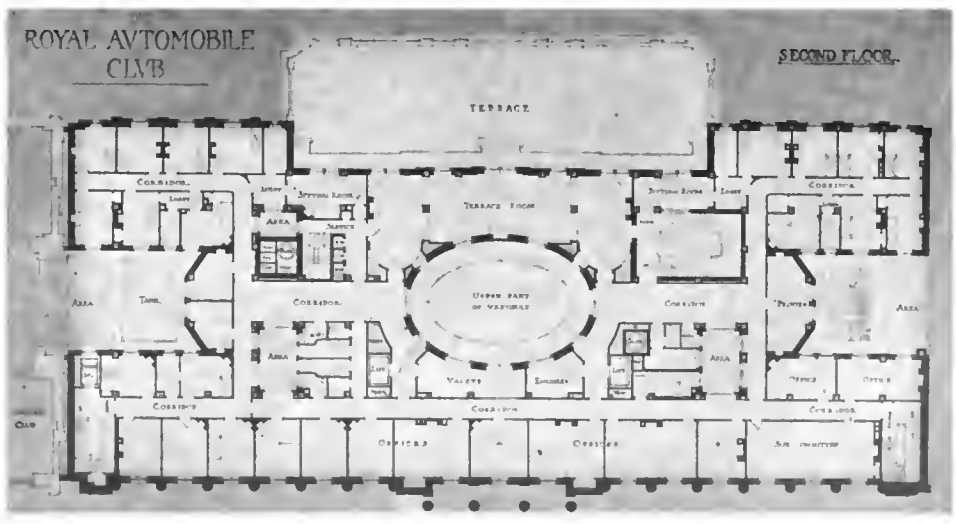
FROM Francis S. Swales, a London architect and correspondent of *The American Architect*, New York City, comes a story concerning the new clubhouse of the Royal Automobile Club. Mr. Swales contributes the following:

It is interesting to note that another example of the French influence will soon be found in Pall Mall, on a part of the site occupied by the old buildings—formerly the War Offices—between the Carlton Club and St. James' Royal Palace grounds, in the new home of the Royal Automobile Club. Pall Mall (though it possesses a few aberrations) has been more fortunate than most of London's principal streets, in so far that the newer buildings have been for the most part at least the equals in design of the older structures which they have replaced. The "old" building of the Alliance Assurance Company, opposite St. James' Palace, erected some twenty odd years ago, is one of the designs which helped to make the name of Norman Shaw famous. The new building facing St. James' Street, to which the company not long ago removed its offices, is the joint work of Norman Shaw and Ernest Newton, and two shops built on the north side of the street are rather good work by well-known men; but when it was known that the old War Offices—a group of good old structures, including York House, designed by Sir John Soane—were to be demolished, disapprobation became pronounced and general.



English sentiment breeds reverence for anything that is old, regardless of whether or not the object be worthy of it, which, so far as architecture is concerned, may be understood when one looks upon the good, if commonplace, old structures and then upon the pretentious "improvements," one grasps in an instant the national antipathy to "improvements," sympathizes with it and gives the protesting public credit for at least good judgment. The old War Offices were just such commonplace old buildings, with nothing remarkable about them—only plain—not particularly refined—just inoffensive, and the improvement will be a real one. The Royal Automobile Club is to be built from the designs of Mews & Davis, architects, with whom is associated E. Keynes Purchase, the Honorary Architect of the club. The preliminary drawings and photographs of the model accompany this letter and show the design as it will be carried out with the exception of a few changes in the details, which will be effected in the study during the progress of the work.

Impersonal, if not strictly monumental, architecture has been the rule for the best clubs of the "West End," high renaissance being the type of design which has prevailed in Pall Mall. Of the row of clubs extending from Waterloo Place to St. James' Palace (which includes the Athenaeum, Travelers', Reform and



Carlton) the façade of the Travelers' is based upon the design of the Pandolfini Palace in Florence and that of the Carlton upon the Library at Venice. The Royal Automobile Club, which will adjoin the Carlton, follows the precedent, more or less adopted by the other clubs, and owes its inspiration to the former Hotel Crillon-Coislin—now the Automobile Club—in the Place de la Concorde, Paris. It would be difficult to find a more beautifully studied example of modern architecture than the fine fronts by Gabriel facing the Place de la Concorde—there are two buildings, exactly alike, the former Hotel Crillon-Coislin and the Minister de la Marine—second only to Perrault's Colonnade of the Louvre—if indeed to that—this is among the finest columnar façades in the world. It is extremely improbable that any classic design to equal this will be built in England during the lifetime of any one now living, so that any architect who would emulate Gabriel must needs do so in much the same spirit that he might attempt to emulate the Parthenon or the Sainte-Chapelle—to attain as near as the conditions permit the same character of refinement, simplicity and strength.

This character is expressed to an unusual degree in the design for the new Royal Automobile Club. It is large in scale, an essential to monumental effect; the proportions of the *travée* are nearly the same in elevation as those of the buildings by Gabriel, but the effect will be quite different in perspective, due to the column being engaged instead of part of a free screen. Again, in elevation, the central feature of the new building is similar to the end pavilions of the old, but the effect here will also be different —in the French example the corner columns under the pediments are engaged to the pylons and the two middle ones though free are only a half diameter from the pilaster behind. In the building to be erected in Pall Mall the corner columns will be a half diameter in front of a pilaster on the corner of the pylon against which the portico returns, while the middle ones are in screen, due to the wall face being recessed below the pediment to form a loggia. This latter effect is usually a weak one, giving, as a rule, the impression of two buildings joined together, but the present treatment—the latest studies show the pylons at the ends and those at either side of the pediment brought to the same face—slightly in front of the bases of the columns—and the balcony over the entrance door only, thus doing away with the console below the corner columns and placing the balustrade at either side of the balcony between the pedestals to columns instead of in front of them—a distinct improvement upon the elevation sent herewith. The mass of masonry forming an attic behind the pediment now projects beyond the face of the pylons. This arrangement produces the effect, in the model, of a strong frame of masonry round the void in the center and appears to effectually unify the whole front. It will be interesting to see how this will work out in execuation. Internally the building is treated in the "grand manner." There is an uninterrupted vista from the Pall Mall entrance through to Carlton House Terrace. The elliptical vestibule is 48 feet by 32 feet and runs through two stories and is 50 feet high to the ceiling over the central portion. The dining room at the east end and the club room at the west are each 93 feet by 35 feet, and the "Lounge," which on occasions may be used as a lecture room, 108 by 40 feet, including the platform, and 35 feet high. The basement contains a gymnasium and extensive baths, which are accommodated in rooms which are 28 feet high. Included in the baths is a swimming pool 30 by 75 feet.

The Royal Automobile Club will be the first important club building built in London for several years, as a monumental structure of the kind, the only one for many years more. As architecture it bids fair to rank high among the best work of this century in England.

THE new lighting law in France, like most new laws promulgated by a paternal government, in France and elsewhere, which are supposed to be justly applicable to the automobile, is full of anomalies. Of course, this is not to be wondered at. Solons and law-makers have not yet learned enough about the automobile—unless they be automobilists themselves—to be able to put the new locomotion in its proper place.

The new law refers simply to the number plaque on the rear of the automobile; that it must be permanently riveted to the chassis or it must be painted on a fixed portion of the body work, and must be so effectually lighted at night so as to be as visible as in the day time. This of itself is probably impossible, for no matter how brilliantly it may be lighted a moving surface will not be as readily read, as to the inscription it bears, at night as it will be with the light of day. This is undeniable, evident fact.

And the red light which was formerly demanded? Nothing is said about that in the new law, so presumably it is no longer obligatory, and, of course, the authorities will not be able to summon anyone for the omission of it in the future. Not that this matters much; far from it, for the old lamps all had a red prism showing rearward. The new ones, those of Bleriot, Ducellier and others, who are reaping a harvest off the sale of this new automobile accessory in France, have no provision for this red light whatever, contenting themselves with giving as an effective illumination of the rear number plate as possible. Sometimes this is accomplished by reflection, and sometimes by a diffused light showing through ground glass, the latter a very neat method and legible enough when an automobile is standing still or moving slowly. At *vitesse,* even at the regulation six, eight or ten kilometers an hour, it will be another story.

The law says further that all automobiles on the road at night must carry this lighted rear plate; but another law still in force, and which has been in force for ten or a dozen years and has never been rescinded, distinctly states that at a less speed than 30 kilometers per hour—that is, an automobile not capable of making more than 30 kilometers an hour—the number plate may be dispensed with altogether. Therefore, logically, one is not obliged to illuminate a number plate which does not exist. What will actually happen in practice will be seen later. French law deems a suspect guilty until he is proven innocent, and by the same line of reasoning the authorities may be expected to work one an injury—if they feel like it—and beg his pardon afterward, if they express any regret at all. But what about the *dommage interet,* a bogey that lives in France to-day like the faith that all men are equal in the modern republic?

And what does all this prove: simply that automobile laws are the most foolish laws ever enacted as they exist to-day. The red flag law in Britain, whereby every "road locomotive" was obliged to be preceded by a man on foot carrying a red flag, was no more ridiculous than a lighting law which provides for the lighting of a plaque which does not exist.

Passengers to the number of 26 were carried 150 miles by Count Zeppelin recently, in his great dirigible balloon, and served to show, perhaps, better than any feat yet accomplished, the practicability of such a machine. Ten aeronauts and fifteen soldiers were in the party, in addition to the inventor, and were in the air for about four hours, leaving the quarters at Lake Constance and flying for a greater distance than has ever before been covered with such a weight.

What the Clubs are Doing These Days

BOSTON MOTOR CLUB NOW OFFICERED.

BOSTON, April 12.—The Boston Motor Club has completed its organization by the election of the following officers: President, Horace G. Kemp; vice-president, E. A. Gilmore; secretary, Alonzo D. Peck; treasurer, W. K. Farrington; directors, A. P. Teele, J. B. Sullivan, Jr., Arthur E. Adams, H. H. Love, A. B. Henley and R. R. Ross; membership committee, John L. Snow, W. A. Shafer, George Priest, V. A. Charles and K. A. Skinner.

President Kemp is a well-known local amateur autoist who has long taken much interest in club affairs. Vice-president Gilmore is a member of the Whitten-Gilmore company, the Thomas and Chalmers agents, and Secretary Peck is the veteran Boston bicycle dealer and race official. Treasurer Farrington is an amateur autoist. Of the directors, Messrs. Teele and Sullivan are Boston attorneys, Arthur E. Adams is manager of the Algonquin Motor Car Company, agent for the Oldsmobile; H. H. Love is a member of a financial concern, A. B. Henley is manager of the Franklin branch, and R. R. Ross is connected with the Peerless branch. John L. Snow, of the membership committee, is manager of the Peerless branch, W. A. Shafer is the head of the Crown Motor Car Company, agent for the Pullman and Glide, V. A. Charles is the manager of the Inter-State agency, and Kenneth A. Skinner is a former president of the dealers' association.

CROSBY TO BE HEAD OF BIG JERSEY CLUB.

NEWARK, N. J., April 12.—This year a nomination is equivalent to an election in the official list of the New Jersey Automobile and Motor Club. This means that W. Clive Crosby, at present president of the Associated Automobile Clubs of New Jersey, will also become the head of its largest club, as he has been placed in nomination by that organization's trustees. The other nominations are: Vice-president, Clarence Bissell; treasurer, G. H. Simonds; secretary, A. B. LeMassena. The present incumbent of the presidency, Paul E. Heller, declined a re-election, and Dr. J. R. English likewise refused a continuation in the treasurership.

In the board of trustees Mr. Heller, J. L. Adams, Jr., and H. D. Bowman have been named to succeed Joseph H. Wood, W. F. Kimber and A. G. Scherer. The holdover trustees are H. A. Bonnell, Dr. Frank Meeker, F. A. Croselmire and W. C. Shanley.

BRIDGEPORT CLUB HOLDS ANNUAL ELECTION.

BRIDGEPORT, CONN., April 12.—At the annual meeting of the Automobile Club of Bridgeport, attended by nearly 250 resident and non-resident members, Frank T. Staples was unanimously re-elected president of the organization. The other officers chosen were: Ralph M. Sperry, vice-president; F. W. Bolande, secretary; L. B. Powe, treasurer; board of governors, H. H. DeLoss, M. V. Doud, Dr. H. S. Miles, E. W. Fairchild, A. H. Canfield and B. H. Edwards. The nominating committee was composed of H. E. French, Frank Miller and David F. Read.

MARYLAND COURTESY FOR HARRISBURG RUN.

BALTIMORE, MD., April 12.—The Automobile Club of Maryland, through Secretary Darling, has requested Secretary of State N. Winslow Williams to have the State waive its legal right to require Maryland licenses for those who will participate in the endurance run of the Automobile Club of Harrisburg. Mr. Williams has submitted the club's request to Governor Crothers.

SYRACUSE CLUB CAMPAIGNING FOR MEMBERS.

SYRACUSE, N. Y., April 12.—There are now 230 members in the Automobile Club of Syracuse, and there are 250 owners who are not members, and a vigorous campaign has been instituted to secure at least 150 additional members. If this can be done, the activity of the local organization will be greatly increased, a permanent secretary engaged, headquarters established and monthly bulletins issued.

The club is at the present time actively engaged in considering the bills now before the State Legislature.

Through the courtesy of Congressman M. E. Driscoll the Syracuse club has received the latest topographical maps of the State. These will be mounted, and hung in the secretary's office.

PHOTOS WERE OF NORRISTOWN PATHFINDERS.

NORRISTOWN, PA., April 12.—The photographs used in the April 8 issue of THE AUTOMOBILE, in connection with the endurance run of the Motor Club of Harrisburg, were taken by the pathfinders of the second annual endurance run of the Norristown Automobile Club. This contest will be held May 18 and 19, between this place and Hagerstown, Md. The pathfinding party consisted of five cars, sent over the route at considerable expense to the club, and the photographs show the splendid roads which will be covered. The cars making the preliminary trip were a six-cylinder Oldsmobile, driven by T. W. Berger; White steamer, Matheson, Crawford and American Traveler.

DROUGHT AS MILWAUKEE CLUB'S COUNSEL.

MILWAUKEE, WIS., April 12.—The Milwaukee Automobile Club has accepted the resignation of James T. Drought, secretary and treasurer since its organization in 1903, as Mr. Drought could not be induced to remain. Arthur C. Brenckle, one of the leading cigar manufacturers of Milwaukee, has been unanimously elected secretary, and a treasurer will be chosen at the next meeting, it having been decided to separate these offices. Mr. Drought has consented to act as legal counsel, in which capacity he has been valuable. Mr. Brenckle is a charter member of the club, and has taken a deep interest in all of its affairs.

PHILADELPHIA CLUB INCREASES MEMBERSHIP.

PHILADELPHIA, April 12.—At the April meeting of the recently elected board of governors of the Automobile Club of Philadelphia last week no less than 63 applications for membership were favorably acted upon. Chairman R. O. Griffith, of the maps, routes and signs committee, reported that as soon as the full text of the new automobile laws of Pennsylvania, New Jersey and Maryland could be secured and put in type the new road book will be printed and issued to the members. Powell Evans was re-elected president of the board; Stedman Bent as vice-president, and S. Boyer Davis as secretary and treasurer.

OHIO ASSOCIATION ELECTS OFFICERS.

CINCINNATI, April 12.—Harry L. Vail was elected president of the Ohio Automobile Association at its annual meeting. C. J. Forbes, Jr., was re-elected secretary. The directors are: From Cleveland, F. T. Sholes, Harry L. Vail, W. H. Wherry, F. J. Baer, Chas. Weaver, C. H. Hoskins, C. J. Forbes, Jr., J. B. Ayers, W. M. Hager, W. F. Bonnell, B. P. Foster; from Elyria, A. L. Garford; from Youngstown, C. H. Yahrling; from Kenton, James H. Allen; from Akron, Andrew Auble. Secretary Forbes' report showed an increase in membership from 1,180 to 1,604.

A Leading Garage in the Heart of Portland, Me.

The photograph shows the headquarters of the Harmon Automobile Company, 26-30 Forest Avenue, Portland, Maine, which is admirably located as a stopping place for tourists on the route to the Maine summer resorts.

Milwaukee.—Since the fire which destroyed the Sanger garage, the members of the Common Council are proposing all sorts of radical regulations. This subject and the ultimate outcome are of great interest, because the garage is a necessity here, particularly in the fashionable districts. That condition was brought about by the desire of owners to keep their cars in a public rather than a private garage. One result of this has been to produce a lot of very high-class garages, most of which are architectural models. The outcome of the discussion will be awaited with much anxiety by the owners of these expensive places.

San Francisco.—The latest step in the automobile invasion of Van Ness avenue is the announcement of the erection of the Stearns Building, on the corner of Fulton street. This will be a very large building and one that will add materially to the neighborhood. Construction has been started, and possession is expected within sixty days. The Reliance Automobile Company, the local Stearns agents, will move the salesrooms and offices, but the shops and garage will remain at the present location, this segregation being one of the features of the new building.

Chicago.—The new garage proposed by the Chicago Motor Cab Company, to be erected near Huron and St. Clair streets, has been strongly opposed by residents of the fashionable district. Protests have been filed by Joseph Leiter for the Potter Palmer estate, John L. Whitman, John T. Mountain, H. F. Talbot and R. F. Keith. Certain legal points are being considered by city counsel.

Joliet, Ill.—One of the best equipped garages in the State has been opened by George B. Peterson, on Clinton street. It includes a show room, office space, rest and smoking rooms, retiring rooms for ladies, and a machine shop fitted with electrical power and operated by skilled mechanics. The garage has large washstands and space for cleaning and storage.

Des Moines, Ia.—Contingent upon street improvements, the Bernhard-Turner Automobile Company, will erect a large building for garage purposes on Seventh street, just north of Grand avenue. It will be two stories in height, with a front of glass, and completely equipped in every way; garage, washstands, etc., and the property has been secured.

New York City.—John D. Rockefeller has had plans filed for making over the annex to the Metropolitan Riding Academy, at 125 West 55th street, into a garage. The wooden fittings will be torn out, and the building reconstructed in fireproof style, with steel ceilings, terra cotta walls and partitions and cement flooring. A turntable will be installed.

Garage Washstand on the Roof.—To utilize otherwise wasted space, a garage in Sydney, Australia, has arranged its building so that its cars are taken to the roof for washing and general cleaning, and then taken down into the building for storage. The roof is made of reinforced Malthoid and so can be used for this without any danger of leaks or of it wearing out.

Huntington, W. Va.—The Hanley & Kincaid Automobile Company will occupy the new Miller garage, on Court street, between Ninth and Tenth streets, which is one of the largest in West Virginia. The garage section of the building has been completed and the company will take possession at once.

Port Jefferson, N. Y.—The Fred Griswold Garage Motor Company has bought the lumber yard property of John T. Mather, and will erect a garage and dredge the mill creek so that motor boats can get to the shop. Benjamin West, of Bayport, is to be an active member of the company.

Pittsburg, Pa.—B. F. Benson is erecting a garage on North Craig street, near Luna Park, for Studebaker cars. The Hamilton Automobile Company, agent for the KisselKar and the Middleby, has broken ground for a new home at Hamilton and Dallas Avenues.

Louisville, Ky.—The Olds Motor Works has purchased, for $25,000, property on Fourth avenue, near York street, on which to build the largest garage in the South. It will be of brick construction, and used both as a selling headquarters and garage.

Cumberland, Md.—The Queen City Garage Company, recently incorporated, will continue the garage and repair business which has been established for some time. J. H. Johnson, B. H. Biays and L. Reed are interested.

Charlotte, N. C.—Osmond L. Barringer has made plans for building a one-story garage, 50 by 180 feet, with a showroom and office in the front, and in the rear an electrically driven machine shop; cost, about $10,000.

Indianapolis, Ind.—Work was started recently on the two-story building for the Gibson Automobile Company, at 235 N. Pennsylvania street. This building, 37 by 125 feet in size, will be used as a showroom.

Springfield, Mass.—Work has been commenced upon a new garage for the Hampden Automobile Company at 60 Taylor street. It is 50 feet wide and 115 long and will be completed in sixty days.

Atlanta, Ga.—Edwin P. Ansley, 71 N. Forsythe street, is having plans prepared for a ten-story reinforced concrete building for storing, repairing and displaying automobiles.

Toronto, Ont.—The Canadian Cycle and Motor Company intends erecting a three-story building for its Toronto headquarters at Richmond and Bay streets.

Hobart, Okla.—C. F. Newcomer, of the Hobart Motor Car Company, has completed arrangements to erect a new garage on Washington avenue.

Garage of the St. Paul (Minn.) Motor Vehicle Company.

Three Famous Fishermen and One Able-Bodied Seaman.

Showing the result of a day's sport at Knight's Key, Florida, participated in by three prominent New Yorkers: General Manager Alfred Reeves, of the American Motor Car Manufacturers' Association; John C. Wetmore, of the "Evening Mail," and Nathan Lazarnick, the well-known photographer. The able seaman stands complacently at the extreme left, apparently well satisfied with a good day's work.

Lozier Company's Team for Races.—Harry Michener and Ralph Mulford, who have driven the Lozier cars in the principal events in which these have competed in the last three years, will continue to drive in the events in which the Lozier cars are featured during the coming season. Harry Cobe, who twice assisted in breaking the world's 24-hour record with a six-cylinder Lozier last year, will also be a member of the Lozier team. Michener is now on the Pacific coast, and will take part in some of the western events during the next six weeks; after which he will return east, either for the 24-hour race at Philadelphia or the Cobe stock car race at Chicago. Mulford will be seen in races for the last time this year, and will take no part in racing events after the Founders' Week race in Fairmont Part next October. Harry Cobe will probably take Milford's place as a regular driver on the Lozier cars after this season.

Many Visitors See Pierce Factory.—Approximately 1,500 people have been shown through the new factory of the Pierce-Arrow Motor Car Co., Buffalo, in the past twelve months, according to officials who have been able to judge the numbers fairly accurately, and hereafter an actual count will be made by those in charge of the reception room. The plant has become one of the show places of the city, and for that reason the visitors have not been confined wholly to the class that buys cars. Among the visitors have been between 60 and 75 men from other automobile factories, and several from large European concerns, all looking for ideas on how to better their own establishments. The Pierce is one of the largest and most modern in its construction among automobile factories, and a cordial welcome is always given to visitors, no matter what their purpose may be.

Tropical Trade in Waverley Electrics.—The island neighbors and dependencies of the United States are proving excellent customers for American-made automobiles. A short time ago a Waverley electric was sold to a sugar planter of San Domingo. Last week an order was received from Honolulu for a model 67 Waverley victoria phaeton. This is an especially popular model for southern climates and the appearance of a new electric carriage of this type in tropical Hawaii can hardly fail to attract attention among other possible purchasers. A letter recently received by the Waverley Company from Manila, P. I., refers to the active competition in that faraway city between automobiles of French, Spanish and American manufacture, and expresses an urgent desire to see a greater number of American cars represented in that city.

Chicago Society Woman Drives Baker Electrics.—Mrs. Guy R. Pierce, a society woman of Chicago, is an enthusiast on electric automobiling, and recently said: "I do not see why ladies should doubt that an electric automobile can be operated easily. Any woman can drive an electric at her own pleasure, without danger of soiling gowns, gloves, or temper." Mrs. Pierce has purchased one of the new Baker electric coupes, and has been asked by many of her friends to show them how to run the car. She also owns one of the Baker electric runabouts, a car which has the general outlines of a gasoline car, but which is really an electric with a mileage radius of 100 miles at an approximately high speed.

A Million Dollar Challenge.—With evident courage of its convictions, the Diamond Rubber Company is taking the position that the automobile owner should have first-hand knowledge of tires. In a rather striking advertisement printed this week, a "Million Dollar Challenge" is issued to car owners to acquire such knowledge, and users of Diamond tires, as well, are urged to check up their respective experiences. The Diamond Company is very much in earnest, and the advertisement referred to is well calculated to attract a great deal more than passing notice.

Winton Output of Large Cars Sold.—Notice has been issued by sales manager Churchill that the entire output of 60-horsepower Winton sixes has been sold. Mr. Churchill says, "We do not count a car sold until we have the money for it. If we were to follow the general practice of regarding agents' blanket orders as sales, our entire output of both 48 and 60-horsepower cars would have been gone long ago. Sales have been particularly active all winter, and at the present rate we shall have no more 48-horsepower cars to sell within three weeks."

Bosch Offers Prizes to Racers.—The Bosch Magneto Company has announced that it will give cash prizes to the drivers of the first three cars in the Coupe des Voiturettes, the light car race, in France this year. The driver of the first car will get $600, that of the second $200, and the third $100. The only condition is that each car shall be equipped with the Bosch magneto. As to other prize awards on occasions of this season's events of major importance, announcement will be made later.

Record Sale of Glide Cars in Peoria.—The old adage that "a prophet is not honored in his own country" has not held in the county of Peoria, Ill., according to G. G. Luthy, secretary of the Bartholomew Company, manufacturer of the Glide automobiles. This concern has sold 18 of its 1909 cars to buyers in the city of Peoria, in which the factory is located, and six to those in the same county, outside of the city, making 24 sales in Peoria county.

Rapid in New Factory.—The Rapid Motor Vehicle Company, of Pontiac, Mich., has moved into its new factory, which now gives it four acres of floor space. H. G. Hamilton, the general manager, reports that 80 per cent. more business is on the books of the concern than in the busiest season of last year.

Baltimore to San Francisco Tour.—Harry C. Weiller and family, of Baltimore, Md., are arranging to make a trip across the continent to San Francisco, in their 50-horsepower Welch car. Many side trips will be taken, and it is expected that about 10,000 miles will be covered.

IN AND ABOUT THE AGENCIES.

Remy, Detroit.—The Remy Electric Company, of Anderson, Ind., manufacturer of high tension magnetos for automobile, marine and stationary gasoline engines, has opened a branch selling office at 471 Woodward avenue, Detroit, Mich. The new distributing center will be under the management of C. E. Brelsford, formerly manager of the Detroit branch of the Witherbee Igniter Company and the Stewart & Clark Mfg. Company. Mr. Brelsford will be assisted by A. J. Roth and Dell Stines, both of whom are experts on automobiles and accessories.

Stearns, Philadelphia. — G. Hilton Gantert, formerly of The Motor Shop, has been awarded the Philadelphia agency for the Stearns car, and has opened up handsomely appointed salesrooms at 510-512 North Broad street. As the Motor Shop handled the Stearns in the Quaker City up to within a few months ago, Mr. Gantert is peculiarly well qualified to advance the interests of that car in Philadelphia.

Kissel Motor Car Company of New York.—In changing its location, the name of the metropolitan distributor of the KisselKar also was changed from the Apthorp Motor Car Company to Kissel Motor Car Company of New

York. Its new headquarters are at 1875-77 Broadway, and Fred S. Dickinson, the manager, has made arrangements for additional lines of cars from the Wisconsin factory.

E-M-F, Tampa, Fla.—The Tampa Harness & Wagon Company are the agents for the E-M-F in this city. The company's territory embraces several counties in southern Florida.

PERSONAL TRADE MENTION.

H. S. Firestone, president of the Firestone Tire & Rubber Company, has returned to his home in Akron, O., delighted with Cuba as a perfect spot for automobile touring. He says that the roads are being continually improved by the government with coral stone, which is proving to be the finest material imaginable. It works down into an asphalt-like surface that requires little repair and remains perfectly smooth. Mr. and Mrs. Firestone toured in company with James Couzens, of the Ford Motor Company.

Frank B. Hower, chairman of the A. A. A. Contest Board, in a friendly chat recently, said: "I think I will not care to run another Glidden tour after this year. I am glad to have this one to manage, in order to apply the experience I gained in the last two contests. The manufacturers this year will get the best run for their money they ever have had. I am making certain of this, but in another year I hope there will be some one else to bear the burden of the work and worry."

F. C. Gilbert has resigned as general sales manager of the Toledo Motor Company, the successors to the Pope Motor Car Company, of Toledo. Mr. Gilbert has been with this company, and its predecessors for fourteen years, and during the period of the receivership marketed for the receivers over a million dollars' worth of goods, holding the sales record for the allied companies He expects to take a short vacation and will then take up active work again.

J. L. Davidson, superintendent of the former Rainier automobile factory at Saginaw, Mich., has severed his connections with that plant, now the Marquette, and taken a position as superintendent of the American Motor Company of Indianapolis. The seven foremen who were under him in official capacity, as an expression of their goodwill, presented him with a valuable ring. Mr. Davidson is succeeded by W. R. Willett, at the Marquette works.

Milton Lusk, who has entertained so many automobilists on Glidden tours and at shows by his music on Gabriel horns, will shortly join the sales forces of the Pittsburg branch of the Olds Motor Works. With C. H. Foster, of the Gabriel Horn Company, it is probable that Mr. Lusk will be at the keys of a horn in the A. A. A. tour this summer.

E. Percy Noel, advertising the Moon Motor Car Company, is the author of the words of a new popular song. "Tell Me Your Love in Wireless," brought out by the Noebur Publishing Company, St. Louis. W. P. Burnet, a well-known composer, wrote the music.

Russell Dale formerly sales manager of the Celfor Tool Company, has been appointed the Chicago representative of the Carpenter Steel Company, of Reading, Pa. Mr. Dale will have his headquarters in the Commercial National Bank building.

T. P. Myers, sales manager for the Rapid Motor Vehicle Company, Pontiac: Mich., has just returned from a month's trip through the Western States, where he recently appointed several new agents for his company.

L. H. Kittredge, president of the Peerless Motor Car Company, has been made a member of the executive committee of the Cleveland Industrial Exposition, which will be held in Cleveland from June 7 to 19.

J. J. Evans, who marketed the first American Mercedes automobile, has taken charge of the output of Frontenac cars, made by the Abendroth & Root Company, Newburgh, N. Y.

F. A. Stock, for some time associated with the Franklin line in Cleveland, has been appointed manager of the Jewell Motor Car Company, of that city.

Thomas Henderson, vice-president of the Winton Company, leaves Cleveland this week for a Pacific coast tour.

TAXICABS AND TRANSIT.

Greenfield, Mass.—A company has been organized in Greenfield to operate a line of automobiles to Turners Falls and Northfield. One car to seat twelve has been purchased and will be run to the former place on an hourly schedule, each trip consuming about 15 minutes, commencing May 1. The car for the Northfield line will seat 16 to 20, and will make three round trips daily, one in the morning and two in the afternoon, beginning with the summer season.

Marquette, Mich.—The Marquette County Traction Company has been organized to run an automobile service between Marquette, Ishpeming, and Negaunee. Four large passenger cars are to be put into the service, and will make regular trips between the three cities every day.

Philadelphia.—The Whitemarsh Valley Country Club has purchased a 40-horsepower White steamer opera bus, which it will use in running between the clubhouse and railroad and trolley stations at Chestnut Hill.

RECENT BUSINESS CHANGES.

Gilbert Manufacturing Company Separates Lines.—The Gilbert Manufacturing Company, New Haven, Conn., makers of the Gilbert tire cases and other automobile accessories, has separated its business in this trade from that of making corsets. In doing this a new concern has been incorporated under the old name, and the Gilbert Corset Company was formed to carry on the original line. F. E. Bowers has bought a controlling interest in the new firm and will continue in the active management as in the past.

C. S. Houghton, Baltimore.—New salesrooms and a repair shop have been opened by C. S. Houghton, the local agent for the Overland cars, at 6 East Read street. Mr. Houghton formerly had his headquarters in the Calvert building.

TO DOUBLE CHALMERS PLANT.

Detroit, Mich., April 12.—It was announced to-day that the Chalmers-Detroit Motor Company has decided to double the capacity of its plant. A new building, an exact duplicate of the present main building, will be erected in time for occupancy September 1. This will be 60 feet wide, 400 feet long, and three stories high. The new building, like the present main building, will be of concrete construction throughout.

WOODWORTHS AT NIAGARA.

Niagara Falls, N. Y., April 12.—The Leather Tire Goods Company, Newton Upper Falls, Mass., has just completed a new two-story factory at Niagara Falls, which it will occupy after May 1. The entire manufacturing plant and office will be moved to Niagara Falls the latter part of April, and all correspondence should be addressed here after May 1.

The new factory is located on Whirlpool avenue, near the Whirlpool Rapids. It has over 10,000 feet of floor space, and with the improved machinery which is being installed, will have a capacity of over 300 treads per day. This new location will make it more convenient than heretofore to obtain Woodworth treads, for Niagara Falls is one of the best shipping points in the country.

NEW AGENCIES ESTABLISHED.

Brush, Dutch Neck, N. J.—Hiram Cook & Sons. For the eastern half of Mercer County, including Princeton, Lawrenceville, Hightstown and Pennington.

White Steamer and Jackson, Tampa, Fla.—Florida Gas Engine and Supply Company.

White, Pittsfield, Mass.—Tracy & Robison, 184 North street. For the Berkshires.

Rapid, Pittsburg, Pa.—Keystone Automobile Company.

Chase, Boston.—N. S. H. Sanders.

RECENT INCORPORATIONS.

Duluth Motor Vehicle Company, Duluth, Minn.—Capital, $50,000. To manufacture, buy, sell, import and export automobiles, motors, engines, machines, etc.; sell gasoline, do a general garage business, etc. Incorporators: A. G. Fitzgerald, Evelyn S. Fitzgerald, C. W. Fitzgerald.

Crowley Iron and Machinery Company, Ltd., New Orleans.—Capital, $15,000. To install an automobile garage and do a general repair and machine shop business. President, S. D. Wilder; vice-president, J. P. Burgin; secretary-treasurer, C. E. Warren.

The Anderson Motor Car Company, Anderson, Ind.—Capital, $10,000. To manufacture motor vehicles. Incorporators: T. Chandler Welbes, Spencer M. Hickman, Edwin G. Worden, U. Grant Hodson, E. Fred Dice.

Nadall-Van Sickien Manufacturing Company, Chicago.—Capital, $50,000. To manufacture automobile accessories. Incorporators: G. L. Wilkinson, W. A. Scott, C. A. Richmond.

Berger Taxicab Company, Brooklyn.—Capital, $25,000. To manufacture and rent automobiles, wagon trucks, carriages, etc. Incorporators: H. A. Berger, W. Wing, P. Wilds.

Green Taxicab Company, Brooklyn.—Capital, $25,000. To purchase, deal in and rent automobiles and motor vehicles. Incorporators: D. T. O'Brien, F. G. Strobel, H. Jacobs.

L. W. Holt Company, Buffalo.—Capital, $10,000. To sell automobiles, power boats and engines. Incorporators: R. A. Kellogg, Elizabeth A. Nauth, Frances A. Moses.

American Body Company, Buffalo.—Capital, $10,000. To manufacture automobiles and other vehicles. Incorporators: E. A. Selkirk, E. J. Freitas, J. W. Kelly.

Motor Company of Dover, Del.—Capital, $100,000. To manufacture automobile and other motors. Incorporators: J. H. Hughes, J. L. Wolcott, Franklin Temple.

Sloane Motor Company, Chicago.—Capital, $35,000. To do a general manufacturing business. Incorporators: A. W. Baer, William M. Sloane, D. M. Carter.

Beacon Motor Car Company, Boston.—Capital, $10,000. To do a general automobile business. Incorporators: F. H. Young, L. B. Pinkney.

Oklahoma Taxicab Company, Oklahoma City, Okla.—Capital, $10,000. Incorporators: Joseph Huckins, Jr., C. R. Riggs, H. R. Connor.

SOME RECENT TRADE PUBLICATIONS

The Rambler Magazine: Thomas B. Jeffery & Co.—This magazine, which does not accept a single line of advertising material, and is mailed free to a multitude of people each month, is the unique publication known as the "Rambler Magazine," published by Thomas B. Jeffery & Company, Kenosha, Wis., makers of the Rambler car, in the interest of 14,000 Rambler owners. The latest issue, now being mailed, is practically of standard magazine size, and in it appears articles descriptive of touring, with pictures especially posed by some of the best photographic artists in the country. The Rambler people offer big prizes to amateur photographers for specimens of their work, and these are reproduced in the issues. This publication was started several years ago for circulation among Ramhler car owners. Then owners asked to have it sent to their friends, and these have increased to such an extent that the free circulation has now soared to high figures. Mr. Jeffery, maker of the Rambler, believes that the furnishing of specific information to owners and prospective buyers is of great benefit to the industry in general. Free copies of the latest issue will be sent to any one making the request to the publishers.

The White Company, Cleveland.—The White Company, in its latest publication, the catalogue of the 1909 product, has followed much the same successful lines as heretofore, with perhaps an improvement, for its new hook is a pleasure to read, and highly instructive as well. Not only are the various models described, but the parts of the White construction are thoroughly analyzed, and to those users of gasoline cars who do not understand the operation of the successful steamers, this catalogue would be especially valuable. The hook is a handsome one, from cover to cover; well bound, well printed, and with cuts which could not be improved. Phases of White desirability are discussed, the newly adopted Joy valve action explained, as well as that of the steam generator system, which is so often misunderstood or misquoted. Excellent photos of the complete cars, chassis, and parts, are given to illustrate the reading matter. Two chassis sizes are built by the White Company this season, one of 20, and the other of 40 horsepower, and the specifications are given in full.

Banker Wind Shield Company, Pittsburg, Pa.—Two types of wind shields are being made by the Banker Wind Shield Company, as shown by the firm's recent catalogue, one a single folding, and the other a double folding type. In hoth, heavy plate glass is used, and they both have features that make them desirable, such as rubher buffers in the ball and socket joints, and full length hinges, to prevent rattling. The douhle folding shield is, of course, the one featured, for it can be so folded over the hood of an automobile as to be out of the way, even when the hood is opened. There is no metal strip across the center of the glass to obscure vision, and shelves of metal are used to support the glass. The frame is made of one piece solid stock, set in chanelled ruhber, and the clamps, telescoping tuhes, etc., are made of highly polished brass. The wood is of walnut and mahogany, with piano finish. Accurate measurements for all makes of cars are kept so that mail orders can easily be attended to.

Buckeye Manufacturing Company, Anderson, Ind.—The new catalogue of the Buckeye friction drive cars deals mainly with the friction feature and the engine used. The former embraces two elements, a friction disc and the driving wheel, mounted upon an extension of the crankshaft. The disc is mounted, sildably, upon a jack shaft from which the drive is by enclosed silent chain to the rear axle. Actual service has proved all of the Lambert claims, not only on touring cars of little weight, but upon the heaviest of commercial trucks. Four models are listed, varying in price, carrying capacity, size and type of motor. The extremes are Model A-1, which will carry 2-3 passengers, lists at $800, and has a 20-horsepower, two-cylinder opposed engine; and Model B-2, with roomy seven-passenger hody, four-cylinder vertical motor of 40 horsepower, and priced at $2,000. Between the two are a number of others all medium priced, but varied in capacity and equipment to suit the various needs.

Northwestern Storage Battery Company, Milwaukee, Wis.—Storage ignition and lighting hatteries, electric cabin and enclosed car lights, electric side and rear lights for automohiles and motor boats, battery charging outfits, etc., manufactured by the Northwestern Storage Battery Company, are ably described and illustrated in a catalogue recently published by this concern. Several sizes of ignition batteries are made: 6-volt, 60-ampere; 4-volt, 60-ampere, and 6-volt, 40-ampere. Then there is a motor boat battery of 6 volts, 120 amperes, and a lighting battery which can be made in various sizes, for house, farm or boat lighting, to be used in connection or without, a gasoline engine and dynamo charging outfit. A great variety of lamps is offered, the searchlights being furnished with tungsten globes, and the side and dome lights with the regular caroon lights. Special lights for speedometers, etc., are also made, and all types shown and explained in detail in the catalogue.

Breeze Motor Buggies, Carthage, O.—The Jewell Carriage Company has issued its catalogue describing the several styles of motor buggies built by it, sold under the trade name of Breeze. There are two chassis sizes illustrated, one of 13-14 horsepower, and the other of 17-18; both with double oposed offset air-cooled engines, single chain drive to a counter-shaft, and double side chain drive to the rear wheels. A two forward speed planetary transmission is used. There are three general styles of bodies mentioned, one with a single seat for two passengers; one a surrey with a capacity of four or five; and a model with a seat for two in front and with a light spring wagon body so that merchandise can be carried at the rear. The wheels are 37 inches in diameter, and fitted with solid rubber tires. The steering is by wheel, and the engine control levers are on the steering post, underneath the wheel.

Kearns Motor Buggy Company, Beavertown, Pa.—Gearless, clutchless, valveless, are the words used to describe the Kearns, which is a new motor huggy or high-wheeler with a two-cylinder, two-cycle, air-cooled motor and a friction transmission. While these words at first sight seem extravagant, upon closer acquaintance the car is seen to bear out the claims. The two-cycle motor used is the Speedwell, which is well known, and of course has no valves. With a friction transmission no clutch is used, this being one of the advantages of this form of power conveyance. With this form, also, gears are eliminated. As the catalogue aptly puts it, "the Kearns cars are noted for the mechanical features they lack; they have no speed change gearing, no differential, radiator, water tank, pump or water jackets, no clutch, valves, gears, cams or springs, and no punctures."

The K-W Ingition Company, Cleveland.—In a little booklet which combines the features of a catalogue and an instruction book, the K-W Ignition Company, of Cleveland, is setting forth the particulars of its 1909 products of magnetos, coils and spark plugs. Five different styles of magnetos are made; one for belt spark only with a friction drive; one for helt drive, especially for machines like the Ford runabouts; one for motor boats, and two which can be used with gears, belts or sprocket and chain drives and either for jump spark or make and break, the same model heing used with slightly different arrangement for the different types of ignition. These magnetos can he used for electric lights at the same time that they furnish the ignition current. K-W spark plugs and coils are described in detail, giving the advantages and construction, with advice for the care of them.

Alden Sampson Mfg. Co., Pittsfield, Mass., is distributing Catalogue C, a book descriptive of commercial motor vehicles built by this concern. These include the twenty-ton road train and principally the new four-ton truck chassis. The latter has been so constructed as to be equally suitable for use as an omnibus. The good features noticed on casually glancing through the book are the spring-suspended engine, three-point suspension for the transmission, automatic spark advance, the driver manipulating the throttle only, and the enclosed chain. The chain case is dust-proof and oil tight, being made of sheet metal, is liberaly provided with inspection and adjustment covers, while at the same time acting as a radius rod. This will undoubtedly be a large factor in the life and efficiency of the chains, the most important element in the driving mechanism.

The Royal Tourist Car Company, Cleveland.—The announcement of the Royal Tourist for the 1909 season was looked forward to with a great deal of expectancy before the shows, and the catalogue, which appeared simultaneously with the touring cars, is in keeping with them. Bound in light blue with an attractive cover drawing, and having in its center two of the prettiest photos of cars yet seen in the season's booklets, both being views of the new touring cars, make it especially attractive. A front view is also shown, as well as those of the engine, transmission, and other parts. The construction of the car is explained in detail, and the general matter in the catalogue conveys a splendid impression of the newest product of the Royal Company.

American Napier Company, Jamaica Plain, Mass.—The American Napier Company, in its catalogue of the 1909 product, announces that three types will be manufactured: The 60-horsepower, six-cylinder car; the 40-horsepower, four-cylinder car, and the 20-horsepower, four-cylinder "Nike" type runabout. The full description of these models is given in the new publication, calling attention to the construction of the frame, brakes, steering joints, clutch, engine, gears, and other points worthy of note. Ease of control and ignition is emphasized, as well as the lubrication features. In tabulated form, the specifications are so given as to allow of an easy comparison between the various models, or for reference.

Buggycar Company, Cincinnati.—In presenting the 1909 catalogue of "Buggycars," this company reveals an unusual machine. This is a high-wheeler with a horizontal opposed, air-cooled motor of 12-horsepower located in the center of the car. From the flywheel, the drive is by friction to a side shaft, the latter driving the rear axle through bevel gears. Side leaf springs are used, the frame is of angle iron, 1 1-8 tires, are solid, and the same on both, 42-inch front and 44-inch rear wheels. Tiller steer is employed and a wide range of buggy bodies may he had. As an option, cable drive may be had, if desired, in place of the friction shaft drive.

Motor Car Equipment Company, New York City.—Everything for the autoist but the auto, might well be the title of this 1909 catalogue. The firm is accessory dealers, and the catalogue is a description in detail of the accessories handled, all of which are of a very high grade and well known to the trade. Contrary to the usual catalogue of supply houses this one is printed on very excellent paper and the cover is of an attractive design. This has a border made up of scenes from the Vanderbilt and other races, within which is another border. Inside of this in turn is grouped a lot of accessories, about every imaginable thing in this line being included.

Trojan Motor Company, Louisville, Ky.—This concern is issuing a binder with inserted leaves to the number of 7, 8 by 10 in size, descriptive of the Trojan automobile motors. These are of the air-cooled two-cycle two-port type, and range from one to four cylinders. The same size cylinders are used on each, and are 4½ inches in diameter, 8, 16, 24, 32 for the respective one, two three and four-cylinders, in which it agrees exactly with the A. L. A. M. rating, although the latter is intended for four-cycle motors. Two views of the single-cylinder are shown.

Dow Tire Company, New York City.—This is a hooklet, 5 by 9 in size, descriptive of the Dow non-deflation inner tuhes. These are of great service in the elimination of punctures and the annoyances attendant upon cuts or punctures. Coupled with this, the fact that these tubes do not lose anything in resiliency easily accounts for the present popularity of this accessory. The booklet describes their manufacture, includes many letters of recommendation, and finally a list of prices and sizes in both inches and millimeters.

Ohio Seamless Tube Company, Shelby, O.—This is a history of the growth of the seamless steel tube industry in this country, dating from 1890. The development of the buildings, which is the mark of the progress of the company, is pictured in a series of photos. These show in a graphical way the story which the text tells. The 4 by 8 hooklet closes with a description of the process of making steel tubing.

Cortland Forging Company, Cortland, N. Y.—Catalogue D is a real book, 6x9 in size, bound in cloth and illustrates the product of this company, which includes bow sockets, arm rails, top and body irons, as well as shifting rails and top parts or components of carriage or automobile tops. A very complete index is a pleasing departure from the usual run of catalogues.

Hornecker Motor Mfg. Co., Genaseo, Ill.—No. 5 catalogue of the Torpedo Motorcycles, showing the various one and two-cylinder models made by this firm. A considerable portion of the book of 40 pages is devoted to testimonial letters from Torpedo owners all over the country, particularly California, where many hill climbs and races have been won on this make.

Garvin Machine Company, New York City.—Edition D of the illustrated catalogue of machine tools is a standard sized, 6 hy 9, well printed hook of 96 pages. The text, descriptive of the Garvin one, two and three-spindle profilers, vertical spindle millers, duplex millers, and other tools, is printed in three languages. These are English, French and German.

INFORMATION FOR AUTO USERS

A Compact Pressure Register.—A clever device which is destined to add to the peace of mind of the automobilist is the new Pressuretell valve, shown in the illustration, which not only retains the air pressure within the tire, but at the same time will indicate at a glance the pressure existing. The recent agitation for higher air pressure has developed this article as a pressure indicating medium, and as it was a self-evident necessity, the natural question was—why not incorporate it as a part of the valve itself?

PRESSURETELL VALVE.

The device is arranged inside of the regular and well-known Schrader valve, all of the parts being standard, so that it is interchangeable with any valve now in use. On screwing off the protecting cap, the interior portion of the valve rises, displaying a graduated stem which, read at the top line of the stationary part, gives the pressure. The graduations read from 40 pounds at the top down to 120 pounds, at 5-pound intervals, as the pressure within being greater, the graduated stem will be pushed out farther, so the graduations must read in reverse order. The pumping of the tires or deflation of the same is in no way interfered with. The Pressuretell valve is marketed by Indicator Sales Company, 1773 Broadway, New York City.

Don't Risk Losing Your Auto by Fire.—It is often said that an ounce of prevention is worth a pound of cure. This must be true of fires if of anything, so any means for preventing or extinguishing automobile fires is worthy of attention. Among the successful fire extinguishers is the Goodson, which has the additional good features of being small, compact, efficient, and above all, reasonable in price. This is put up by the makers, Goodson Electric & Mfg. Co., Providence, R. I., in long tubes of small diameter, which will go into any tool box. The composition of the contents is such that it cannot explode, cannot get out of order, will not freeze, requires no attention, and is so simple that any child can operate it. With all these good features, the retailers should sell them faster than the makers can turn them out. If they cannot, it is a sure sign that the people do not know a good thing when they see it. The quality of taking little room should alone be enough to recommend it. But added to that, non-freezing, non-explosive nature and lack of care speak volumes for it.

GOODSON FIRE TUBE.

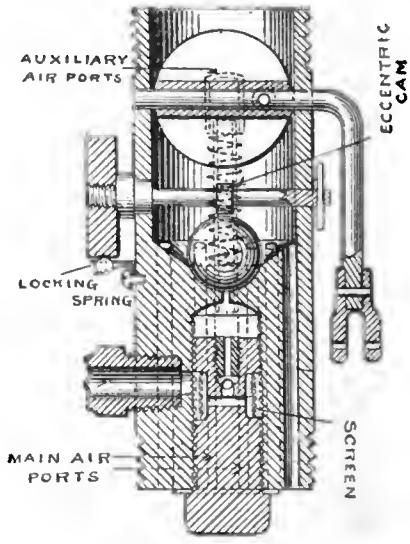
Wridgway Automatic Headlight Shade.—A crying necessity, due to the glare of the average headlight, which blinds approaching drivers and renders roadwork a hazard. The "Wridgway" is made by the Wridgway No Glare Shade Company, 1999 Broadway, New York City. This shade is said to do nothing to kill the glare of the lamp, and in no way is the efficiency of the same reduced. The rays of the light are not scattered, and the projected beam of a headlight is just as effective, but its penchant of damage is aborted.

W-D Spring Cushion Tire.—This tire is designed to eliminate possibility of punctures and blowouts and insure safety at all times. The basis of the puncture and accident proof claim is the laminated Swedish steel springs which form the interior of the construction. These have the form of a modified letter B laid on the flat side, thus bringing the recess uppermost. Into this a heavy beading on the interior of the rubber shoe or casing, fits loosely, the arrangement of

CROSS SECTION W-D TIRE.

the curves being such that it is impossible for the steel springs to cut into the rubber. The use of springs does away with air and the necessity for providing it in the first place and maintaining it thereafter. This means throwing away the pump and with it all tire worry. The springs are very resilient under load, in fact, a depression of three-quarters of an inch is claimed, which is actually more than the ordinary hard-pumped pneumatic. This should make for easy riding qualities, which have been prominent by their absence in other tires with steel as the base. This tire is said to be no longer an experiment, having been tried on rough and smooth roads for between 7,000 and 8,000 miles, and is pronounced by tire and automobile experts to be the acme of perfection in tire manufacture. It is sold under an absolute guarantee, making it the most economical and absolutely safe tire on the market. The W-D Spring Cushion Tire Company is located at 107 West Twenty-seventh street, New York City.

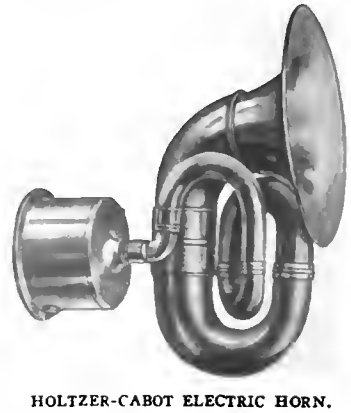
The Ball Does the Work.—In the Shain Ball Spray Carbureter, as the name indicates, there is no spray nozzle, this work being done by a ball. It floats on the entering stream of gasoline and by its weight regulates the flow thereof. This arrangement makes for simplicity in operation, and by eliminating many small, delicate parts also reduces the opportunities for derangement. In the sectional view, the gasoline enters at the pipe on the left, passes through the screen, which is removable, up under the ball, and thence enters according to the suction of the engine. This suction not only raises the ball but also sets it to whirling. The result is to break the stream of entering gas into a thin film, which is thrown against the walls, where the air readily picks it up. From this



SHAIN BALL SPRAY CARBURETER.

mixing chamber, the mixture passes up into the throttle chamber, where at very high speeds additional air is admitted. This is allowed to enter by the movement of the throttle, which at or near the extremity of its traverse, uncovers the auxiliary air ports. The weight and size of the ball is predetermined by the manufacturers, and is unchangeable. Its lift, however, is regulable by means of an eccentric cam. The size of all of the air ports, both main and auxiliary, is also unchangeable, as is the point at which the latter comes into action. So, this device possesses many attractions for the new driver, and the old hand, who desires simplicity. It is made and marketed by Charles D. Shain, Murray street, New York City.

Greater Convenience in Horn Operation.—A new contrivance of great simplicity and very convenient for use when driving, particularly in crowded city streets, is a horn which may be operated without removing the hands from the steering wheel. In driving along crowded thoroughfares, a person's hands are

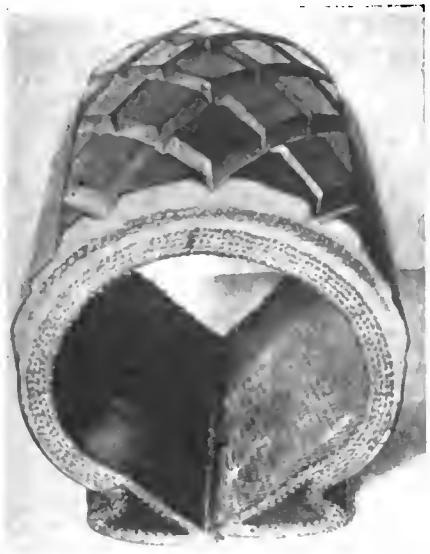


HOLTZER-CABOT ELECTRIC HORN.

rather well occupied by the needs of gear shifting and steering, without anything additional such as a signaling device. A late improvement in this direction is the use of electrically operated horns, which may be operated from any place desired by simply locating the operating button at that point.

A prominent company manufacturing a line of electric horns, the Holtzer-Cabot Company, of Brookline, Mass., has brought out an improved horn which has many new and valuable features which will commend its use. This horn may be operated by either a 6-volt storage battery or by dry cells if preferred. It is so made that the adjustment will not be affected by the jar of the machine running over the road. Moreover, it is also dust and moisture proof. As ordinarily attached to an automobile, the operating push button is placed upon the steering wheel, usually on one of the spokes. It may, in this position, be operated without moving the hands.

New Ajax Non-Skid Tire.—In bringing out its new non-skid tire, the Ajax-Grieb Rubber Company has adopted a distinctive method of construction. Instead of having a moulded tread, the Ajax tread is wrapped on the shoe by the same process by which the ordinary smooth Ajax tire is made. When worn



SECTION AJAX NON-SKID TIRE.

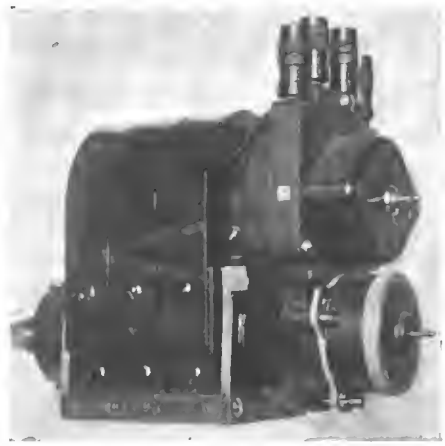
after going at least the 5,000 miles for which they are guaranteed, these non-skid tires can be retreaded without injury to the inner fabric so that they can be run two or three thousand miles more. The new Ajax also has a character of its own in its appearance, its raised parts being quadrilaterals, 3-16 of an inch in depth, arranged diagonally across tread. These are designed to be far enough apart to prevent squeezing and flattening into a smooth surface when under weight, and in contact with the road surface. As the quadrilaterals on the Ajax tread point in the direction in which they run, it is claimed they offer a minimum of resistance and wear. The tire itself is heavier than the smooth model, the 3 1-2-inch size having five plies of fabric. The breaker strip—the strip of fabric between the inner pliable rubber cushion and the tough outside layer—is made heavy, and the same is true of the entire tread layer.

EISEMANN SINGLE-CYLINDER MAGNETO.

Eisemann High Tension Magnetos.—For the coming season the house of Eisemann will produce two types of high tension magnetos intended for the two radically different classes of work, but with similar electrical connections to previous models. The two types will be for use with a separate coil and without a coil, in which case the magneto is a complete ignition system in itself.

In the first style, the make-and-break mechanism is fitted so that it can be detached quickly. This is accomplished by fitting it on a round plate which is readily removable. The contacts are fiber on steel, the cam being steel and the lever carrying the platinum point being fitted with a piece of fiber. The high tension distributer has an automatic cover and arm. The brushes are of steel, used to give the best contact with the least rubbing on the copper. The armature is on ball bearings on the cam side and plain bearings on the driving end. The armature is of the same type as before, the low tension type.

The self-contained type is a departure for this firm, being produced for the first time. The low tension current produced by the primary windings is periodically interrupted by a revolving break, each break producing a high tension current of very high voltage in the secondary winding. This current is collected by means of a slip ring at the driving end and carried to the distributing plate by an insulated lead and carbon brush to the inside of the distributing arm on the distributing plate. This arm is fitted with a long rubber sleeve to secure perfect insulation. For advance, the point of breaking may be displaced by simply



EISEMANN FOUR-CYLINDER TYPE.

shifting the steel shoes on which the fiber block of the breaker lever is kicking. This range of advance is obtained without decreasing the intensity of the spark. The armature is mounted the same as in the first case, ball bearings on the cam side and plain on the gear end. One new feature is the special disposition of the pole pieces, which are cut helicoidal shape. This gives greater smoothness and a larger advance.

The materials used are nearly all of them specially made for this purpose, a number of them being made to order in Germany. They are thoroughly tested out at the French factory. The American sales of all Eisemann products are handled by Lavalette & Co., 112 West Forty-second street, New York City.

To Reduce Internal Tire Friction.—One of the reasons why tires heat up as they do is because of the very high internal friction, between the tube and the shoe. This may be prevented by the use of some anti-friction powder or liquid, but of such a nature as will not attack the rubber. Many wise autoists use talcum powder; others rub the surfaces with soapstone; but what is claimed to be the best is a preparation just brought out for the purpose, which is neither talc nor soapstone. It is known as Rex powder and is put up in

HOW REX POWDER IS APPLIED.

one-pound cans with combination sifting top, by the Rex Manufacturing Company, Hartford, Conn. The method of use recommended by the makers is to sift a little into the outer shoe just before applying it to the wheel. By putting the powder into the shoe it comes between the shoe and tube where the friction is greatest.

Can't Steal This Clock.—Any automobile owner who has ever been subjected to the petty annoyance of having his clock stolen will appreciate a new clock so constructed as to be thief proof. In the Safety auto clocks, this feature is made prominent. The form is such that a key is necessary to separate the clock from its holding case. The latter is fastened to the dash by means of interior screws, so that with the movement in place these are concealed and consequently inaccessible. A new feature which has just been added to the safety line is the shield. This protects winders from the various objectionable influences such as moisture and will be supplied on all clocks when so desired at a slight additional cost. The clocks are made by Manasseh Levy & Company, 182-184 Broadway, New York City.

INDEX TO ADVERTISERS

Vol. XX New York—Thursday, April 22, 1909—Chicago No. 16

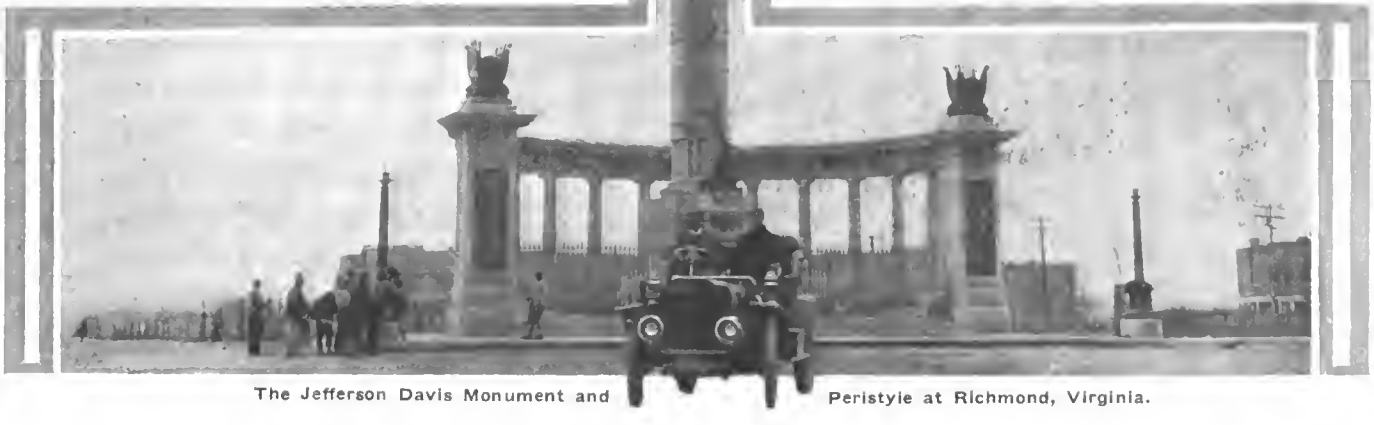
THE AUTOMOBILE

"On to Richmond!"—Nowadays

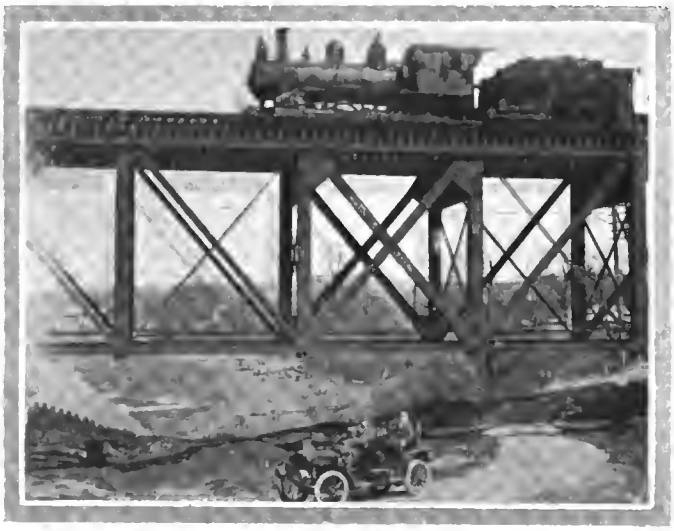
SUDDENLY realizing that an Easter vacation was to be had for the taking, the thought came to mind that Spring would be awakening down Virginia way. Hence the old cry of "On to Richmond!" found lodgment in my brain, and late the same day—which was Good Friday—I was leaving the metropolitan maelstrom in company with friends who accepted promptly the invitation to go along in my White steamer.

We drove to New Brunswick and there spent the night. The next morning we hustled over the road to Trenton, and here, crossing the river, drove into Philadelphia by way of Bustleton. This route proved to be much more interesting than the usual route via Bordentown and Burlington, and, besides, we avoided the ferry at Camden and the narrow east-and-west streets of Philadelphia, with blocks of two-story houses.

Coming into the city by way of the Old York Road and North Broad street, we stopped only long enough to have luncheon and then continued straight out South Broad street. Chester was the next town on our route, and we found the roads south of that place quite as neglected as they were two years ago when we passed



The Jefferson Davis Monument and Peristyle at Richmond, Virginia.



The Rail Bound Steamer and the Trackless Steamer.

through that town on our way to Cape Charles and Norfolk. I make special note of this fact because almost invariably, when covering a route for the second time, I find the roads in better condition than before, thanks largely to the vigorous good roads campaign which the users of automobiles are conducting in all parts of the country.

Soon we were on the fine toll-road leading into Wilmington, and, on reaching that city, we turned off to the southwest and headed for Newark, Del. After leaving Wilmington we were in a section that none of us had before traveled in a car and, consequently, we had to find our way by asking questions at each fork and crossroad. We found the road unexpectedly good, and it did not take us long to reach Newark, and from there to travel to Elkton. Near the latter town the good roads stopped and the road became rather rough, with occasional stretches of sand. Continuing through Northeast and Principio, we reached the Susquehanna River at Perryville just at dusk. The ferryboat happened to be on that side of the river and we were soon across at Havre de Grace.

Chesapeake Bay, South of Havre de Grace.

The fare charged for carrying an automobile on this ferry is $2, which seemed to us rather out of proportion to the distance traveled. However, as there is a decent pier and approach to the ferry at either side of the river, we did not complain.

It will not be long before the ferry at Havre de Grace becomes a thing of the past. The Pennsylvania railroad has recently built a new bridge at this point and has ceded its old bridge to the State (in return for the repeal of certain onerous restrictions in the company's franchise). As soon as a new center pier is built, which is predicted for November 1, there will be a fine highway for the use of vehicles. At the present writing the first highway bridge over the Susquehanna is at Columbia, and the majority of tourists traveling between Philadelphia and Baltimore go that way—probably because of the senseless tradition that there are some great difficulties in traveling by the direct route via Havre de Grace.

We spent the night very comfortably in Havre de Grace at the Hartford Hotel, taking our dinner at Herr Konigsberg's restaurant, where we were served with terrapin soup, oysters right out of the bay, chicken, and a few similar delicacies at the surprising price of fifty cents per head.

Before starting out in the morning we were joined by our old friend, L. W. Tremblay, of the Automobile Club of Maryland, who acted as our guide for the rest of the day's trip. We had not traveled far from Havre de Grace when the good roads reappeared, and we made quick time through Belair and

Ferry Across the Susquehanna River, from Perryville to Havre de Grace.

then to the beautiful Long Green valley, famous as the rendezvous of several hunting clubs. Even faster than the nimble fox runs before the pursuing hounds, we hastened through the valley to its terminus at Towson, and from there it was but a short drive into Baltimore (111 miles from Philadelphia).

Up to a year or two ago tourists usuallly made the trip from Baltimore to Washington by a roundabout way, via Ellicott City. Now a fine boulevard is under construction directly connecting the two cities. More than two-thirds of the road has been finished, and the tourist covers the intervening stretches of bad road with good grace, as he knows that, before another year has passed, the work of building the macadam boulevard between the two cities will be completed.

Only one incident marked our trip into the Capital City. Just as the tip of the Washington Monument came into sight we saw an automobile approaching us at a speed very much greater than that stipulated in the statute. As it flew past us we saw that it was a big White Steamer, in which sat its smiling owner, President Taft, with the members of his family. He acknowledged our salutes by tipping his cap with that display of camaraderie which is usual when White meets White.

We decided to spend the night at Washington, and devoted much of the evening to considering our further plans of "On to Richmond"—the cry which once thrilled so many hearts. We pored over the maps and discussed the pros and cons of the several possible routes to that city, just as must have been done in the dark days of 1861-1865 by those who had in their

keeping the destiny of the nation. But while it took the Union army four years to go from Washington to Richmond, we were determined that we would do it in one day. And we did so, although there is no record of the trip ever having been made before in a day by an automobile. No data has ever been published regarding the route which we covered, and, for that reason, the accompanying map will prove of special interest to those tourists who are not deterred by bad roads, particularly if the bad roads lead through an interesting section of the country.

Leaving Washington on Monday morning (the day after Easter) we crossed the long bridge over the Potomac River and continued parallel with the railroad into Alexandria. On the outskirts of this town we turned due south into the old "Telegraph road," so called because it is along this road that the telegraph wires run to Richmond. Although we made frequent turns during the day, we followed the Telegraph road practically all the way to Richmond, making a few detours here and there at places where we were advised that we could find better roads.

Nothing would be gained by considering the Telegraph road section by section. Almost all of it is bad and much of it is worse. However, I believe that it is only a matter of a few years when this road will be macadamized all the way from Washington to Richmond. But it is the touring conditions now existing of which we speak. There is very little level country in eastern Virginia, and the road goes up and down, up and down. The best roads which we found were of sand, on which,

View of Long Green Valley, Near Baltimore.

Soon after leaving Stafford Court House the road improved a little, and we "crossed the Rappahannock"into Fredericksburg. On the summit of the hill just beyond this town we saw by the roadside a little monument, hardly two feet high, bearing the inscription, "Lee's Hill, Battle of Fredericksburg." How modest a memorial this is, we thought, to the valor of the Confederate troops who, on this ridge, in the closing days of 1862, defeated the Union troops who were advancing on Richmond and drove them back across the Rappahannock with terrible slaughter. Surely, if every little Northern town can boast an elaborate Soldiers' Monument, Fredericksburg should have some more imposing memorial of the victory achieved there by the "Boys in Gray."

Typical Road Almost Anywhere Between Washington and Richmond.

After we left Fredericksburg behind us the road seemed even rougher than before. There were more creeks to be forded, but none of them was either very wide or very deep. In fact, considering how sparsely the country is settled, we were a little surprised to find substantial iron bridges over all the more im-

by "straddling" the ruts and by opening the throttle a little wider than usual, we made almost as good progress as we had on the previous day. Even the worst roads made no difference to us except that we did not cover very much more than ten miles an hour. The roads were rough and washed out, and often each of the four wheels would be on a different level. We found many miles of corduroy road, in which the "corduroy" was missing every few yards. After dropping gently from the "corduroy" we would bring our car almost to a stop at the point where the "corduroy" began again. Then, opening the throttle wide, our car would climb to the new level—almost a foot above the old—without even jarring the passengers. But, of course, this kind of driving takes time, and instead of making Fredericksburg, the halfway point, for luncheon, as we had planned, we had traveled by 1 o'clock only as far as Stafford Court House (52 miles from Washington).

This community consists of a court house, two general stores, a jail, and a fine old-fashioned farmhouse, owned by the clerk of the court, Mr. Bryan. Mr. Bryan's claim to local fame is that he is a cousin of "William J.," the Presidential Marathon runner. However, we shall remember the Bryans of Stafford Court House as the providers of as fine a luncheon as was ever set before a party of three hungry tourists; price (for the three), "A dollar—if that is not too much." I think, too, that they will remember us as having given them their first automobile ride (twelve in the car).

Along the Banks of the Occaquan River.

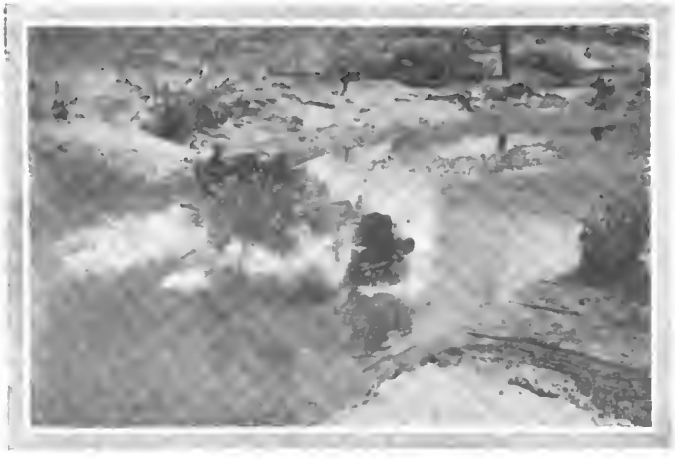
After Lunch with W. J. Bryan's Cousins, Stafford C. H.

portant streams. After our travels in Georgia, a year ago, we were prepared for anything in the fording line and were, if anything, a little disappointed that we did not find any deeper water on our route.

There is an end to all things—even to a Virginia bad road, and about the time our speedometer registered 95 miles from Washington we were on a road which would have passed inspection

Old House Near Fredericksburg, Riddled with Bullets.

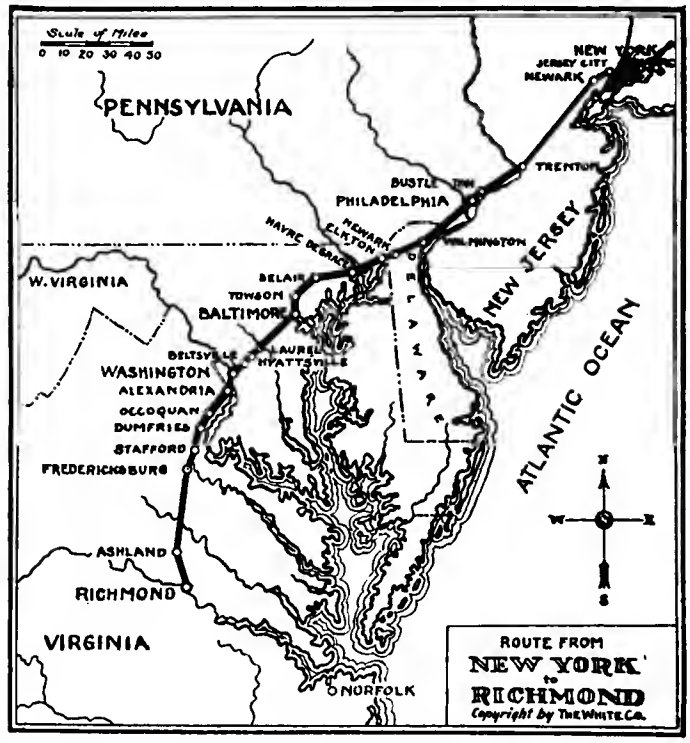
in central New York by the standards prevailing four or five years ago. Just as daylight was fading we reached the little town of Ashland, and here we stopped to light our lamps. We could not get our acetylene lamps working, and, therefore, drove into Richmond by the light of our oil lamps, which, of course, would have been inadvisable had the roads not been in very fair condition. We reached Richmond in time for a late supper at the luxurious Hotel Jefferson, 125 miles from Washington and 375 miles from New York. Thus, without a single involuntary stop, even for tires, we had traveled from the metropolis to the old capital of the Confederacy in practically three days and had passed through five States—New Jersey, Pennsylvania, Delaware, Maryland and Virginia. A journey of this character emphasizes the utility of the auto as an up-to-date form of travel.



White Steamer Fording a Stream Near Ashland, Va.

When Richmond Was Reached We Took Our Ease.

At Richmond I found myself once more in a country which I had previously covered (reaching there via the Shenandoah Valley), and, therefore, decided to terminate the trip, as we were once more beginning to think about telephone calls, unanswered letters, and those other things which, in this imperfect world of ours, intrude upon the mind and time of the tourist. We spent much of the following day in driving around Richmond and its suburbs, and late in the afternoon turned the car over to the Old Dominion Line for shipment back to New York and returned by train, each of us wearing a coat of tan that would do credit to a Glidden tourist the third day out from Kalamazoo.



MOTOR PARKWAY RE-OPENED TO TOURISTS.

New York, April 19.—After being closed to automobilists during the last two months, the Long Island Motor Parkway was opened on last Saturday. At present the Meadow Brook lodge, situated near Garden City and the Meadow Brook Hunt Club, at Westbury, is the only entrance and exit, and cars may pass through it between the hours of 8 a. m. and 7 p. m. on Saturdays and Sundays. Active construction on the course has progressed during the Winter, the right of way having been cleared of trees, and the grading, bridging, fencing and roadmaking east from Bethpage to Lake Ronkonkoma and west from the Meadow Brook lodge to the Queens-Nassau line are receiving attention now. Within a short time extra gangs of laborers, concrete mixers and steel workers will be employed.

WOMEN TO RACE IN FAIRMOUNT PARK.

Philadelphia, April 19.—Permission has been granted by the Fairmount Park Commissioners for an automobile obstacle race to be held by the members of the Movoganto Klaubo, a body of enthusiastic women automobilists. No date has as yet been set.

What the Glidden Pathfinder is Finding

CHICAGO, April 17.—Guard well your thermos bottles, ye Gliddenites given to acquiring a thirst which the town pump will not quench. Note carefully that these receptacles for goat's milk, bubble water, and other elixirs of life blow cold when you leave Detroit on the morning of July 12 next, for they must needs serve as oases in many an arid waste.

It isn't that Michigan will be lacking in vernal beauty. Nature has dealt kindly with the Wolverine State across which Glidden tourists will wend their way in Midsummer. For much of the way the route selected by Pathfinder Dai H. Lewis leads the tourist across rippling brooks and past sylvan dells where lakes of crystal clearness nestle, delighting the eye, but—

It was a raw April morning, with one of those winds that chills to the marrow blowing a gale, when the E.-M.-F. "30" bearing Pathfinder Lewis, E. LeRoy Pelletier, of the E.-M.-F. Company, Official Photographer Krohn, the driver, and the "Innocent Bysitter," trundled into Paw Paw, a thriving village of 1,600, after plowing a course for some hours through a sea of mud caused by a combination of rain and snow.

"At last," murmured Pelletier, who after the exposure to which he had been subjected resembled an animated iceberg more than anything else.

With a deliberation that was exasperating under the circumstances, Lewis clambered down from his seat beside the driver, ambled across the road, and dragging a ruralite to one side talked earnestly with him for a moment. Then he returned to the car.

"He says he doesn't know, but we might try the hotel," said Lewis, as the car sped forward.

Two blocks further and a halt was made at the village inn, where the landlord, sans coat and vest, was standing on the walk superintending the unloading of a sample trunk. Laboriously a quintet of chilled travelers made their way over to the local boniface, and Pelletier, acting as spokesman, propounded the fateful question.

"Gosh all hemlocks, no," ejaculated the astonished landlord, in tones that were plainly audible across the street. "You can't get a drop of whiskey in this town for love or money. This is a dry county, you know."

Sadly five pairs of eyes were turned in the direction of the car, where reposed two empty thermos bottles, the filling of which at Kalamazoo, the last life-saving station passed, had been overlooked.

Then the watchful Pelletier was seized with an inspiration.

"Come on, fellows, we'll get something," said he, leading the procession to a shop a few doors distant, where a sign announced ice cream soda and soft drinks.

"Land sakes, no, we won't have no ice cream soda for two months yet," was the comforting information handed out by the proprietress of the shop, who had emerged from a rear room wiping her steaming hands on a kitchen apron. "We ain't got no soft drinks, neither." This proved to be a true statement of fact, and for once the redoubtable Pelletier was nonplussed. Ten minutes later when we left the shop, after investing in a number of souvenir post cards, he was standing on the sidewalk in front of the village grocery eagerly devouring a quart of half ripe strawberries in a vain endeavor to assuage the thirst that had been growing with startling rapidity ever since it was discovered that Paw Paw was not an oasis.

There were other points along the line where similar attempts would have been equally fruitless, but no further effort was made. By July these dry spots will be still more numerous, at least two large counties through which the Glidden tour will pass having gone strongly for local option at the recent election, with the result that even blind pigs and speakeasies will be hard to locate after May 1.

Whether premeditated or purely accidental, it happens that the first night's control at Kalamazoo is located in the wet belt, although Battle Creek, only a few miles away, will be dry. Not that this will matter to the Gliddenites, for they are proverbially abstemious; but there seems to be a deal of satisfaction in being in touch with a base of supplies at all times, and the presence of even a well-stocked thermos bottle has been known to ward off thirst just as surely as inability to secure wet goods creates a desire, all of which goes to prove the axiom that a bottle of prevention is more efficacious than a barrel of cure.

Sometime, somewhere, I had read or heard that pathfinding was great sport. Fortunately for the author of that statement, I am unable at this time to recall either his name or address. I

An Illustration Which Tells Its Own Story.

know better. There may be latitudes in which at this season of the year you can drive across country day after day without suffering inconvenience. There is at least one where you can not, as I learned to my entire satisfaction.

When you face biting winds hour after hour as the car speeds along, encounter clouds of sand that at times hide the road from view, splash through mudholes hub deep, and battle with a driving snow that makes progress next to impossible, all within a few hours, you begin to realize that pathfinding is no sinecure, and your envy of the men entrusted with the task shrinks appreciably. Add to this the joy of piling out of the car in mud ankle deep, picking your way over to a farm house where you are greeted effusively by an underfed dog who loses no time in indicating a desire to feast off your calves while you endeavor to pacify him, knocking at the door, awaiting the arrival of the entire household, and then, after you have shivered and shook for a little matter of five minutes or so, discovering they are unable to enlighten you on the point in which you are in doubt, and you appreciate as never before what such a trip as this means.

"Some folks says it's three an' a half miles, some says it's four, some says it's four 'n a half, an' there's others says it's five. I dunno how far it is," was the interesting information vouchsafed by one woman in answer to an inquiry from Lewis.

"Which road is the best?" inquired Lewis, urbanely.

"The swamp road that runs down past here, leastwise most folks says so, but I don't know," came the non-committal reply.

Back in the machine again, Lewis gave the word to proceed, when in shrill feminine tones there came the cheering announcement:

"You can't go through the swamp road, though. The bridge is busted down, and the road's all under water." After due deliberation, we decided not to go through the swamp road, and fifteen minutes later learned that had we followed the instructions given we would have been far off the course. But the natives are a sociable lot, and you are given a hospitable reception wherever you stop.

If asking questions was all there was to it, pathfinding would not be such an irksome task. That is only an incident of the journey. With pencil and pad in hand, Lewis sits beside the driver for hour after hour, taking down the mileage and distinguishing points as the car spins along, and at night transcribes his notes for use in the official guide book that next Summer will describe the course so clearly that the veriest amateur could not go wrong. There are photographs, hundreds of them, taken by the way, and these will show every turn to be made.

Next July, when the Glidden tourists leave Detroit on their way to Denver, conditions will be ideal, and there will be no suggestion of hardship. Neatly printed guide books will tell them where to go and what to do. They may marvel at the completeness of the book, but they will have no conception of what its compilation meant, of the long, cold rides, the endless detail, the vast amount of labor involved.

If they knew what I know about pathfinding—but they will not, so what is the use of dwelling longer on that point? And it is because of what I know regarding pathfinding that I am not envious of Lewis and associates on their trip to Denver.

LEN G. SHAW.

OFFICIALLY STARTED AT DETROIT

TYPICAL MICHIGAN SCENE

NEAR BATTLE CREEK

GETTING DIRECTIONS

DELAWARE RUN.

WILMINGTON, DEL., April 19.—The Delaware Automobile Association has decided to hold an endurance run during the latter part of May. The route will probably be to McCall's Ferry, Pa., along the Susquehanna River.

PATHFINDER IS PLOUGHING THROUGH THE WISCONSIN MUD.

BUFFALO, N. Y., April 20.—The Glidden pathfinding expedition is by this time well on its way to Minneapolis, on the latter part of the first leg of the tour, and about a quarter of the total distance has been mapped out in shape to go in the official guide book. Starting from Detroit on April 12, the party stopped the first night in Jackson and the second in Kalamazoo, which is to be the first night stop of the contestants. On the third day the route-layers made South Bend, Ind., and on Thursday reached Chicago, the second night stop of the real tour. From the Windy City the path-finding car proceeded to Madison, Wis., which is to be the third overnight stop.

The pioneers are making a more careful survey than ever this year, owing to the unfamiliarity of the country which is to be traversed. The route will be entirely new to the Glidden tourists of former years, with the sole exception of the stretch between South Bend, Ind., and Chicago, which was covered in 1907. Frequent stops are made to take pictures, as all the important turns and forks are to be illustrated in the guide book. The roads have been found very muddy, but their character promises better conditions in July.

The present plans for the tour call for a period of about eighteen days and a distance of about 2,000 miles. There will be two intermissions of two days each, however, one at Denver and the other probably at Minneapolis. Denver automobilists are reported to be raising a fund of $10,000 for the entertainment of the tourists, so the weary wanderers may look forward to a good time on the Saturday and Sunday to be spent in that city.

It will be noted that both the time and the distance are a little longer than for any former tour, and this is expected to afford a more strenuous test of the cars. However, the plans are as yet tentative and subject to change, as it may be discovered that some of the trips are impracticable. No official announcement will be made until Mr. Lewis has completed his survey.

Arrangements for the night accommodation of the tourists are already being perfected, especially for the ten days in which they will be housed and fed in Pullman cars. This is expected to be a welcome novelty, as the accommodations will all be equally good and the price will be determined and paid in advance, and the "knockers" will have no chance to complain of uncertainty and overcharging. There will be many of the features of camping out, without the disadvantages, for often the Pullmans will be found on sidings out in the prairies, where the coyotes will sing their lullabies.

Although a few still favor rules that permit a number of cars to be tied at the finish with perfect scores, there are more manufacturers who welcome the conditions of a true contest, in which it is certain that a definitive winner will be evolved. In fact, many would favor rules so strict as to leave no perfect scores at all, the car with the least penalization to be the winner. No one expects a car to cover 2,000 miles, over all kinds of roads, without the least stop or adjustment, and the granting of a dozen or more so-called "perfect scores" under such conditions is only a source of criticism.

The greatest value of a cross-country tour is to show the public how the cars stand up under the most strenuous usage, and an unrestricted race in which a car may be secretly rebuilt several times over is of no advantage to anyone. It is of the utmost importance that the cars travel on a rigid schedule and that a close account of all repairs be kept. Moreover, the closer the contest the more interesting it will be, and the more valuable will be the publicity obtained. Charles J. Glidden, the donor of the trophy, will accompany the tourists this year, as usual, riding in the Premier pacemaking car with Chairman F. B. Hower.

Entries at the regular fee will close May 15, the earliness of the date being due to the many arrangements to be made for the accommodation of the party. Entries made up to June 15 will cost $100 extra, but positively no post entries will be received.

NEW PHASE IN THE NEW YORK TO SEATTLE CONTEST.

IT is barely possible that changed rules and manufacturers' approval in the endurance contest from New York to Seattle may result shortly, if rumors emanating from responsible sources materialize. Great opposition has been found by Mills & Moore, the Eastern managers, to certain provisions in the rules announced, and the lack of regulations of speed and interchangeability of parts, so these may be altered to suit the manufacturers who voted against the event. If this is done it is probable that the members of the Manufacturers' Contest Association may raise the ban placed upon it, although not necessarily entering. Following a visit of John Kane Mills to Detroit, Tuesday, came the report that the manufacturers have been asked by letter from the chairman of the rules committee, H. E. Coffin, whether the matter of the trans-continental contest shall be reopened. A daily schedule of 200 miles as far as Denver, and then go-as-you-please, are the changes suggested.

In the meantime the Thomas pathfinder is battling with snow, deep mud, broken bridges and no roads at all, in Wyoming. It left Denver on Wednesday of last week, reached Cheyenne that evening over good prairie roads; pushed through 40 miles of snow to Laramie on Thursday; 91 miles to Hanna on Friday, the first 71 of which, to Medicine Bow, was good, and the remainder nearly impassable; 20 miles to Rawlins was sufficient work for one day on Saturday; Sunday was spent in Rawlins while a gang of laborers by the order of the road commissioner tried to make some of the roads west passable; and, Monday, Green River was reached. The road conditions have been such as to almost prevent movement, but it is expected that they will be better in Idaho and Washington, where State appropriations of $50,000 and $125,000, respectively, have been made to improve the roads for the contest.

Enthusiastic receptions have been accorded the crew by automobilists and authorities, and they have been accompanied by pilot cars since leaving Denver.

DEATH OF GEORGE P. DICKEN.

PARIS, April 17.—George P. Dicken, well known to many American automobile visitors to Europe as the automobile and aeronautic reporter of the Paris edition of the New York *Herald*, suddenly died recently at Monte Carlo, where he was reporting the motor boat races. Mr. Dicken was the first to obtain and tell of the European success of Wilbur Wright, and consequently secured a notable beat for the *Herald*.

GEORGE B. SELDEN IS MARRIED.

ROCHESTER, N. Y., April 19.—George B. Selden, president of the Selden Motor Car Company, and licensee of the Selden patent on automobiles, was married to Miss Jean Shipley on last Wednesday morning. The ceremony took place at the home of the bride in this city, and immediately thereafter Mr. and Mrs. Selden left for an extended tour. As a wedding present the bride received from her husband a 1909 Selden touring car.

GIANT'S DESPAIR ENTRY BLANKS ISSUED.

WILKES-BARRE, PA., April 19.—An even dozen events will constitute the fourth annual hill climb of the Wilkes-Barre Automobile Club, as shown by the entry blanks which have just been issued. Under the sanction of the A. A. A. and with the understanding that the contest on Giant's Despair, the Wilkes-Barre Mountain, will be the national event of its kind, this will be held on Monday, May 31. The classification has been made according to price and piston displacement, as laid down in the rules of the national organization, and the contestants will be divided into seven sections, according to price; two by piston displacement; one free-for-all, and two special classes, one for members of the local club and one for Quaker City Motor Club visitors.

The regulations under which the affair has been held in the past successfully will be in force this year. The course, which is 6,000 feet in length, with a rise of 700 feet, giving a grade varying from 11 to 22 per cent, will be guarded by efficient police, probably the famous State Constabulary. The contestants will all be given a flying start and none will be allowed to descend until each event is over. An electric timing system will be installed and guaranteed to operate. The Hollenback trophy, offered to cars whose piston displacement is between 301 and 450 cubic inches, will be one of the principal prizes and it must be won three times to secure it for permanent possession.

The entries will close on May 26, with George F. Lee, chairman of the contest committee. The fee for each event has been set at $15. The list of events follows:

Event 1—Gasoline stock cars, selling for $850 or less.
Event 2—Gasoline stock cars, selling from $851 to and including $1,250.
Event 3—Gasoline stock cars, selling from $1,251 to and including $2,000.
Event 4—Gasoline stock cars, selling from $2,001 to and including $3,000.
Event 5—Gasoline stock cars, selling from $3,001 to and including $4,000.
Event 6—Gasoline four-cylinder stock cars, selling for $4,000 or over.
Event 7—Gasoline six-cylinder stock cars, selling for $3,000 or over.
Event 8—Free for all. Cars of all types and motive power.
Event 9—Gasoline stock chassis with piston displacement of 451 cubic inches, not to exceed 600. Minimum weight, 2,400 pounds.
Event 10—Gasoline stock chassis with piston displacement of 301 cubic inches, not to exceed 450. Minimum weight, 2,100 pounds.
Event 11—Cars owned by members of the Quaker City Motor Club only.
Event 12—Cars owned by members of the Wilkes-Barre Automobile Club only.

ALL DIXIE NOW WANTS AUTO RACES.

ATLANTA, GA., April 19.—Successes at Savannah, Daytona, Atlanta, New Orleans and other cities, have stirred the whole South into a racing craze. The complaint long ago infected the large cities and now the small towns have been reached. The latest candidate is Fitzgerald, Ga., a town founded not many years ago by G. A. R. veterans and their families and now numbering perhaps 3,000 citizens. A three-days' meet has been scheduled for June 8, 9, 10, and according to report "500 cars are expected to take part."

SAVANNAH HOPES FOR GRAND PRIZE.

SAVANNAH, GA., April 20.—At a meeting of the executive committee of the Savannah Automobile Club action was taken, giving authority to the chairman to request the Automobile Club of America for early advice as to whether another Grand Prize race is to be held, and if Savannah will be the scene of the event. Not until the A. C. A. is heard from will the Savannah club take any further steps toward the race.

BRITISH DOUBT OF FLORIDA RECORD MAKING.

One of the leading English publications, *Motor*, prints a picture of George Robertson, the well-known driver, and, while calling attention to his Florida time trials at the wheel of the Benz car, cannot resist the temptation to insert in parenthesis that "it is alleged" the figures were made. The particular reference is to the five miles which the Benz covered in 2:45 1-5.

RULES FOR NEW JERSEY RUN ANNOUNCED.

NEWARK, N. J., April 19.—Rules requiring above all things a strict observance of the automobile laws of the State have been announced by the race committee of the New Jersey Automobile and Motor Club, to govern its endurance contest, May 22. Open only to amateurs, the regulations are of a nature new to this part of the country, although conforming to those of the American Automobile Association. Penalties for arriving at the two controls ahead of time, for work done on the motor, and for stops en route, with observers on each car, are provided for.

The event may be entered only by owners of automobiles who are club members in no way connected with the trade, and the cars must be driven either by the entrant or one of the immediate family, no chauffeurs or mechanics being allowed at the wheels. There will be three classes: A, for cars to and including 20 horsepower; B, for those from 21 to and including 30; and C, for those of 31 and over. In addition to the driver and observer, who will occupy the front seats, the full complement of passengers must be carried, and in the case of touring cars, there must be one person for each 18 inches of the width of the rear seat. The driver will be the only one allowed to make adjustments, except to tires, unless permission is secured from the observer, and then the time of the other persons will be charged against the car at double rate of, and in addition to, that of driver.

The route as suggested has been adopted, going to Hackettstown via Chatham, Madison, Morristown, and Schooley's mountain, and returning via Stanhope, Dover, Montclair and East Orange. This circuit is 95 miles in length, and must be covered twice, checking at Newark and Hackettstown each time.

The substance of the penalty list as announced is as follows: To arrive at Newark more than three minutes ahead or behind time on either circuit, 2 points; to stop the motor without making repairs or adjustments, 3 points; to stop the motor to make repairs, adjustments or replacements, 2 points; to stop the car on either circuit after leaving Dover, unless in case of tire trouble, exceptions made when held up at railroad crossings, or for other reasons beyond the control of the driver, 3 points; to repair or make replacements or adjustments, with motor running, 1 point; to replenish with oil or gasoline at any other place than the clubhouse in Newark or the American House in Hackettstown, 1 point. Driving the car in circles in order to delay the arrival at the Newark control will be penalized 2 points. Entry blanks may be secured from the club secretary, A. B. Le Massena, 64 Park place, Newark.

BUSES BARRED FROM RIVERSIDE DRIVE.

The recent action of the Board of Park Commissioners, of New York City, in debarring the Fifth avenue motor buses from using Riverside Drive, has aroused much indignation. The company started the service in response to the popular demand, but has been obliged to suspend it temporarily.

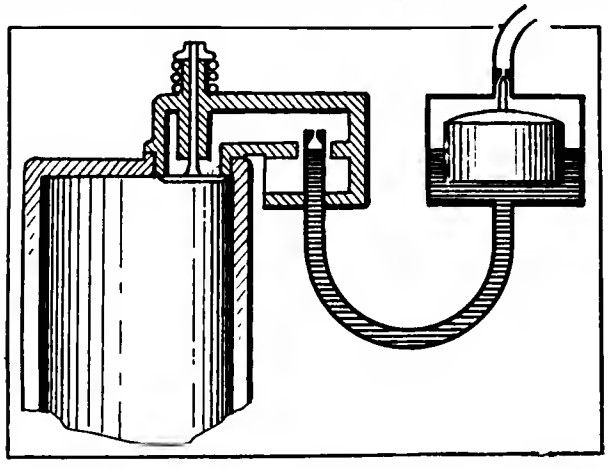
One of the leading landscape architects expressed himself as in favor of the service, saying that the trees should be trimmed to a height of eighteen feet from the road surface as in Paris and other European cities. Harold A. Caparn, treasurer of the American Society of Landscape Architects, is also favorable to the trimming process, and placed himself on record as follows: "The fact is that Riverside Drive is a public parkway, and should therefore be made available to the public as fully and freely as possible, consistent with the proper preservation of its beauties which constitute the greater part of its usefulness. I sympathize with the Park Commissioner, and commend him for his zeal, but his enthusiasm conflicts with public interest."

In the interim, the people in the neighborhood, who encouraged the installation of the service, are anxiously awaiting the outcome. It is urged in favor of the motor bus service that the increasing demand for transportation facilities in that part of the city may result in the establishment of a street car line on the drive, which would destroy its value as a beauty spot.

What to Do When the Carbureter Won't Work

By Morris A. Hall

A CARBURETER is a device for vaporizing liquid fuel. The fuel ordinarily used in the automobile engine is gasoline, and the majority of carbureters are arranged to convert this into a gas. This is done by mixing air with it. Air is used because the fuel itself lacks sufficient oxygen for complete combustion, and air is the cheapest oxygen carrier at hand. If gasoline were self-sufficient, neither air nor other oxygen carriers would be necessary. In that case, the fuel could be vaporized in a closed vessel by simple agitation, such as paddles would afford.



Scheme of Operation of the Original Maybach Carbureter.

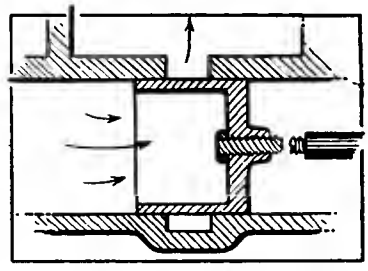
The carbureters now in use attain this result in a variety of ways. The early devices were mainly of the surface type, in which the air passes over the surface of a body of the fuel, picking up some of it. Another early form circulated the air around gauze, wicking, or other surface saturated with fuel. Both of these methods are in use to-day, but in combination, and not as the sole source of gas. Thus, Benz used a vaporizing device of this sort on his earlier machines.

Another very old method is called the ebullition or filtering carbureter. In this air is forced through a body of liquid, entering at the bottom and in its passage to the top absorbing small particles of the fuel. Daimler began with this style, but later abandoned it in favor of the Maybach float feed spraying arrangement, which was the prototype of the form now in prevailing use. The filtering scheme is, however, still used.

A fourth basis of operation is the spraying or atomizing of the liquid through a very fine nozzle, being picked up in this form by the inrushing air. The common variety is of this kind. The first of this type, the Maybach, as shown in the figure, was remarkable, in comparison with its modern successor, principally for its simplicity. There was a float, controlled by the amount of liquid, and a nozzle. The air entered around the nozzle and mixing with the fine spray of fuel in a chamber directly above the cylinder, was drawn from there into the combustion chamber. Although simple, it was also crude and the heat from the cylinder doubtless had much to do with its success. The nozzle was large, as such sizes go to-day, but in spite of all these defects it worked, and worked better than anything that preceded it.

Defects in the Original Are Not Found in Modern Types.—The original had no adjustment, the opening in the casting measured the amount of air, the size of the nozzle measured the amount of the fuel and the fineness of the spray; there was no means of regrinding the float valve, and thus no way of assuring an even and continuous flow of fuel. The modern adjuncts of the original Maybach device consist of remedies for these defects, and, in addition, a proper means of balancing the float.

To pick out a modern carbureter at random, take the one shown. Like its ancestor, this has a gasoline chamber into which the fuel is admitted by the action of a float, first passing through a strainer. From the float chamber the liquid passes up to and through the spraying nozzle. The weight of the float is so calculated that the level in the final nozzle is just I millimeter (0.04 inch) below the top. This insures that there will always be fuel there for the air suction to draw off. As the chemical action of changing a substance from a liquid to a gas is usually accompanied by the absorption of heat it is advisable to supply a reasonable proportion of this and in that way assist the change of form. In the older Maybach, this was inadvertently done by placing the whole apparatus in close contact with the hot cylinder. In the modern carbureter, placed some distance from the heated portions of the engine, this additional heat is supplied by the jacket water. An alternate scheme is to preheat the air supply by a special pipe from the exhaust manifold.

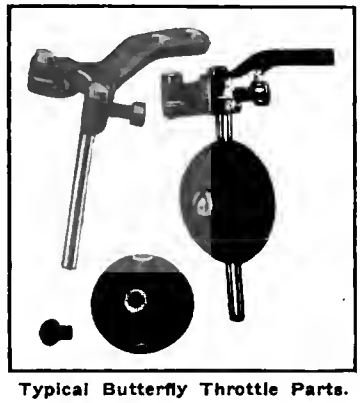


Throttle Stems Sometimes Part.

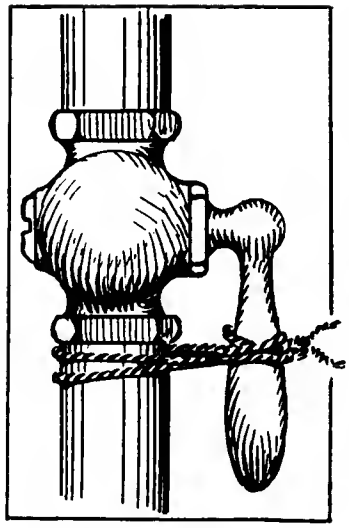
From this mixing chamber the mixture of air and gasoline vapor passes upward into a secondary mixing chamber. This communicates with the inlet pipe through the medium of the throttle valve. Into the latter chamber, the auxiliary air supply (when used) has access, through the auxiliary air valve. This comes into action on very high speeds when the engine is pulling very strongly, for which the proportion of gasoline to air is liable to be too large, so the auxiliary opens, admits more air and thus dilutes the mixture.

Whatever the character of the resultant mixture, it is admitted to the cylinder by the throttle valve, which takes the form known as the butterfly. This is but a flat piece of sheet metal, preferably brass, attached to a suitable shaft with an operating lever on the external end.

And Then the Trouble Begins.—Fuel and carbureter troubles begin with the first turn of the starting crank. The cylinder is cold, so no heat is available to assist in vaporizing. It is impossible to turn the motor over very fast by hand, so that there is very little suction, tending to draw the mixture into the carbureter. This trouble leads to what is known as priming. It is the act of introducing by hand, or independently of the carbureter, gasoline in a form that is readily vaporized. It may be squired into the cylinder head, directly, through the suction inlet valve (if one is used), through the pet cocks on top of the cylinder, or otherwise. To do this, an oil can may be kept on hand, full of gasoline, and reserved for this purpose. Or a rag or piece of waste may be saturated with the liquid, held over the desired opening



Typical Butterfly Throttle Parts.



A Little String Saves Trouble.

and the fuel squeezed out. These remarks apply mostly to old-fashioned motors, but can be used in the case of a very stubborn customer of more recent date.

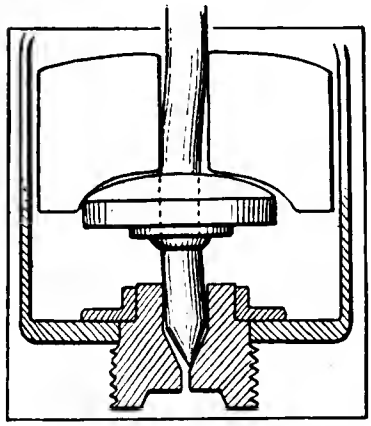
The modern engine starts so readily, however, that such precautions are not necessary. All carbureters are fitted with a device called a priming lever for this particular purpose. The action is to raise the float off of its seat, allow more gasoline to flow into the float chamber, thus raising the head effective for causing a flow at the nozzle, and, from this, the desired result that the gas flows more readily and the motor starts easier. If the prime does not work, prime by hand.

Engine Should Start on the First Turn.—So if all conditions are right, the carbureter is primed and the engine will start on the first turn of the crank. If it does not do so there is a source of trouble which must be remedied first and it is useless to continue cranking. This may lie in the fuel system itself, but exterior to the vaporizer, or it may be in the ignition apparatus. It is well in a case of this sort to start with the gasoline tank and follow the fuel through each step until it apparently reaches the combustion chamber in the form of a properly proportioned mixture of gasoline and air.

To start with the tank, is there enough fuel in it not only for starting purposes, but enough to allow of making the proposed trip? This is readily ascertained by unscrewing the filler cap and inserting a measuring stick. For the purpose a graduated rule is good, but not necessary; any stick or small branch of a tree will answer, or, lacking all these, a piece of wire can be used. A string tied to a very small weight would also do.

Having verified the presence of fuel, the next question to ask yourself is: does it reach the vaporizer as it should? Nearly all carbureters have a drain cock at the lowest point. Open this and if fuel flows out in a steady stream you can be sure that the pipe from the tank up to this point is not clogged. In case the carbureter does not have a drain cock, the same result can be effected by holding the primer for a long time when the gasoline will overflow through the air inlet.

In either case, if there is no sign of gasoline when the tank contains plenty, it is apparent that the feed pipe is clogged and the method of procedure is as follows: Shut off the cock below the tank so that none of the precious liquid can escape, then drain off the carbureter and pipe into a handy pail. Next open the union below the cock in the feed line and the one at the other end of the same pipe. At both places look for obstructions. Then clean the pipe out thoroughly, using flowing water, a piece of wire or other means which are available at the time.



Look for a Bent Needle Valve.

Gasoline Strainer Is Often a Source of Trouble.—Finding nothing here, it will be necessary to continue the search. Look in the strainer of the carbureter to make sure that the flow is not stopped there by the accumulation of dirt and grit, filtered out of the fuel. This should be cleaned often, but like many other dirty jobs is "postponed" from time to time.

Should this source of trouble prove "not guilty," the carbureter itself becomes an object of suspicion. Is the float jammed down upon its seat or are there obstructions there which prevent the flow of fluid? Is the float punctured, or has one of the soldered joints, if a metal one, opened, or is it fuel-soaked, if cork?

A Bent Needle Valve Stem Raises Hob.—To attend to this sort of trouble disconect the priming arrangement, take the cover off of the float chamber (it usually is screwed on with a right-hand thread), and take the float out. An examination of the float will disclose if it is at fault in any of the above-mentioned ways, all of which are comparatively easy to fix. If the float was jammed down, perhaps by priming, the act of taking it out will cure that, provided that the stem of the float is not bent and the needle valve or its seat not injured. If the seat is scored it should be ground in just like any other valve using oil and fine emery. A fuel-soaked cork should be thrown away if another is at hand to replace it, but if not, the cork float should be moved in its position on the stem so that it sets higher in the liquid. In other words, move the cork a sufficient amount to compensate for its loss of buoyancy.

In the case of a punctured float of metal or loose solder, the only real remedy is to resolder in either case. It usually happens that a soldering outfit is not available out on the road and some form of makeshift will be necessary to allow of reaching a place where a soldering iron may be had. If the puncture is on the bottom, it is sometimes possible to accomplish this by inverting the float so that the hole comes at the top. Here the gasoline seldom reaches and if the flow be reduced to make sure of this, it is possible to get to a soldering iron.

Showing the Delicate Needle Point.

A remedy which might be tried in an extreme case of this sort is to fill the float to make it heavy, so that it will have a tendency to sink. Then take a small diameter spring, cut off a short piece of it and place it in the float chamber so that it opposes the sinking action of the now-heavy float. By carefully determining the length, and thus the strength, of this spring, the same action is obtained as would be had if the float were working all right. Of course, if the entrance of the liquid fuel is such that the sinking of the heavy float tends to close rather than open the gasoline inlet, the spring would have to be on the bottom and fairly strong so as to oppose the action of gravity. But if the float works downward to open the gasoline passage the spring will be at the bottom and very weak, simply being there to prevent an excessive flow.

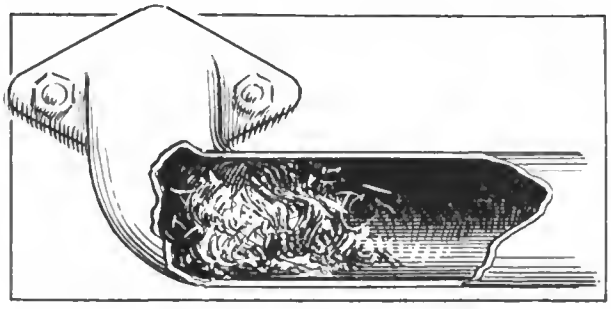
Look Out for a Throttle Loose on Its Shaft.—Now the carbureter trouble has been reduced to a minimum. The remaining troubles might be centered in a clogged spraying nozzle. But this nozzle is readily removed, and with it the trouble, if that be the offending member. If the spray is proven O. K., the throttle is ready for attention. If of the butterfly type it may have become loose on its shaft, or what is the same thing, the operating lever may be loose. In either case the shape and weight are such that it would swing into such a position as would cut off the entrance of gas to the inlet pipe and thus to the cylinder. If the throttle is of the circular sliding or piston form it may not be connected to the throttle rod, but stuck in such a position as to prevent the passage of gas. This sometimes happens when running, and then, apparently, closing the throttle does not stop the engine. The writer had this happen to him once at a time when it was absolutely necessary to stop. The only way that trouble was averted was by the instantaneous closing off of the switch and the application of the brakes.

The last hope of finding trouble in the carbureter system rests with the inlet pipe. If no other trouble is found, take this off in search of misplaced waste or similar substances. The size of the pipe is such that anything in it large enough to cause trouble can be seen instantly and removed easily.

The valve or cock controlling the flow of liquid from the tank should be examined frequently and care taken to keep it in good shape. It must act hard and must be tight, so that no gasoline flows when it is supposed to be shut off. The reason for having it act hard is to prevent it jiggling shut after a long run. This is a real source of trouble, as the engine will gradually slow down and stop without any apparent source of trouble until the tank is looked at when the supply is found to be shut off. A method of fixing it, which is not to be recommended, however, is to open the cock and then hammer the handle so as to jam it tight against the seat, but in the open position.

This makeshift will answer until a place is reached where the taper seat can be reground or tightened in place, if that is what it needs. In case the driver did not wish to do this, and the cock was of the two-way type, open when the handle is parallel to the axis of the pipe, it could be tied in the open position by passing a cord around the cock and pipe both.

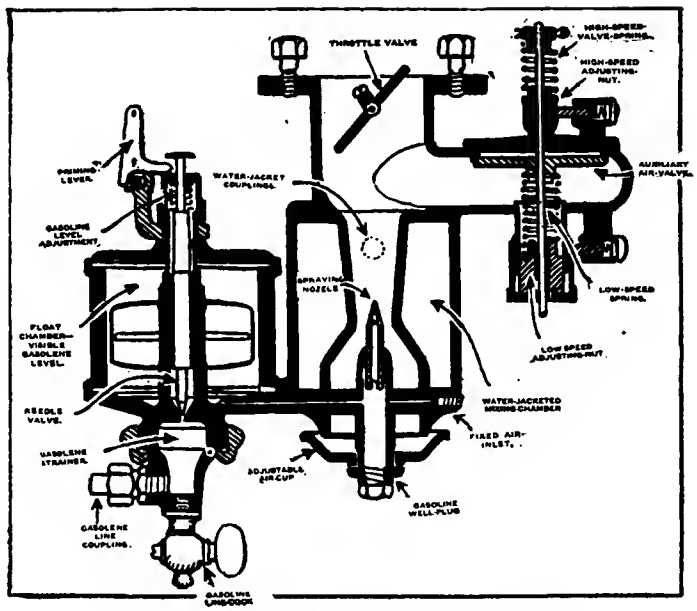
Water in the Gasoline Causes Cuss Words.—In all phases of gasoline systems trouble there is the possibility of water in the fuel. This may be proven by drawing off a little of the liquid into the palm of the hand and spreading it out into a thin even layer. If gasoline, it will vaporize in a few seconds, say, ten, according to the thinness of the layer and the quality of



Waste in the Inlet Pipe Upsets All Calculations.

the "stuff." If it does not pass away as a vapor, leaving the hand very cold, within a minute, one is safe in saying that water is present. Another good way to detect the presence of water in the gasoline is to spread some of the suspected mixture over a flat, clean plate, preferably of sheet metal. The gasoline will spread out in a very thin, even sheet, but the water will not. Globules of water will stand up above the thin level of gasoline and thus betray the presence of the objectionable liquid. If this test is worked out carefully and tried several times, particularly in conjunction with the first named test, it is possible to find the impurity every time. A little practice will give the new operator skill in this direction which will come in handy, in time of trouble on the road, when obliged to buy inferior fuel. A very fine screen of brass will intercept some, but chamois will take out all of the water. In a bad case of this sort the quickest way to remedy it is to draw off all the fuel into a pail, and then, in putting it back into the tank, pass it through a piece of chamois. In a mild case it will sometimes suffice to drain the carbureter only.

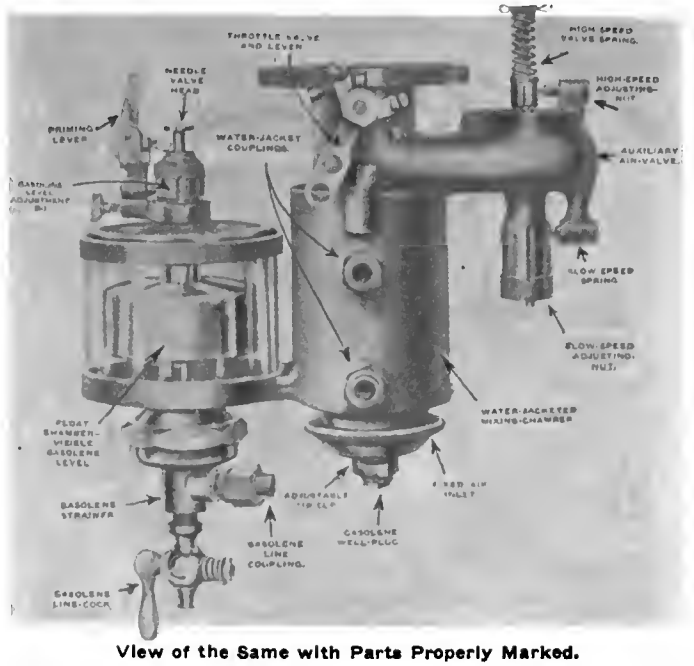
This feature is of more importance than is ordinarily thought, as a single instance will suffice to show. A car with a pressure tank at the rear of the chassis had the pressure valve fail to work, with the result that the bottom of the tank blew out at an isolated place far from repair and supply stations. With it went the gasoline, of course. An examination of the remains of the tank revealed the fact that the water in the fuel, being heavier, had gone to the bottom, and, lying there in quantity, had rusted through the iron tank, making it so weak that it readily yielded to a little excess of pressure.



A Typical Modern Carbureter Shown in Section.

It might be thought that the driver, without gasoline or a tank to put it in, was stalled, but such was not the case. A walk of a mile brought him to a trolley line. A nine-mile ride on this reached a place where gasoline was to be had. Returning with a five-gallon can of fuel, the small outlet at the top was connected by means of rubber hose to the end of the fuel-supply pipe. After inverting and punching a hole in the bottom with a nail, for an air vent, the driver reached home by holding the inverted can in his lap or on the seat beside him, the gasoline flowing to the carbureter by gravity. This is an extreme case, but shows what can be done by determination and head-work.

The two cuts, one above and the other below, show a typical modern carbureter, picked out at random, to illustrate to the novice the various parts. The upper view shows a cross-section and the lower an external view. The various parts are all marked with their proper names, the same parts being named in both views. It will be noticed that the mixing chamber is water jacketed; this is not applied to all carbureters; in fact, this particular make may be had without it if the driver so desires it. The parts previously referred to will all be found in these cuts and properly marked with the name by which they have been called.



View of the Same with Parts Properly Marked.

Automobile Gasoline and Other Available Fuel

Part II

By Thos. J. Fay

TRUE, when the motor was running slow it was doing no work, and loss was 100 per cent. On the other hand, it is necessary to run the motor when the car is not running, and to whatever extent this necessity is indulged in it has a value in comparison with some other motor that refuses to run under the same conditions, on the same fuel economy; in some cases, then, the loss is more. The next best fuel economy was when the motor was running on full load, and as the nitrogen content shows the amount of air used was slightly more than when the motor was running slow. It is very likely that, under full load, a little more air was what was wanted, and the oxygen present, which was but 0.23, rather goes to show that the air was not up to the requirement.

Partly loaded, the losses were quite in excess of what should obtain, due to the lack of air, as shown by lack of oxygen excess, on the one hand, and to the low nitrogen content, on the other. In this case the oxygen excess was 0.3 and the nitrogen was down to 79.6, both of which showings go to indicate that the mixture was too rich. That this is a very important matter is plain to be seen, especially if account be taken of the hydrogen content, which was 2.4, when the motor was partly loaded, which hydrogen is worth about four times as much as carbon, as a fuel.

To some extent this question is complicated by the composition of automobile gasoline in that if the fuel does not burn, in the time allowed, because it is not volatile, sufficiently for the purpose, it is not a carbureter question unless it is found that, despite the inferior grade of the fuel, it will vaporize by preheating in the manner as shown in Fig. 2.

The Principle of Testing Gasoline.—While it is true that gasoline, in which several fractions of the hydrocarbon distillates can be tested by subjecting the same to a distilling process, and when the several fractions are separated, determine the value of them respectively, this process is a long one, and it cannot be conducted excepting with suitable equipment and by men of some skill. If the object is merely to determine if the sample, in any given case, is as good as it ought to be, considering some standard in hand, the best way to get at the facts will be to note the relative volatility of the standard and the sample to be tested. Fig. 4 will serve to convey the idea, in which it is shown that C_6H_{14} (gasoline) is placed on one pan of a suitable set of balances and some of the sample to be tested is placed on the other pan of the balance. If the gasoline evaporates the fastest, the beam will tilt in the downward direction on the side holding the sample to be tested. By plotting a curve to fixed intervals of time it would be possible to approximate the contents of the sample, as it relates to standards of known performance. In a suitably devised weighing machine the several fractions of gasoline will evaporate off in the order as follows:

PROPERTIES OF AUTOMOBILE GASOLINE.

Name.	Formula.	Density.	Volatility.	Calorific.
Butane	C_4H_{10}	0.600	1	
Pentane, iso.	C_5H_{12}	0.628	31	
Pentane, normal	C_5H_{12}	0.626	36	
Hexane	C_6H_{14}	0.674	68.5	7,155
Hexahydrobenzine	C_6H_{12}	0.760	69	
Hexahydrotoulene	C_7H_{12}	0.772	97	
Heptane	C_7H_{16}	0.688	98	7,380
Octane	C_8H_{18}	0.719	120	7,560
Octane, normal	C_8H_{18}	0.707	125	
Nonane, a	C_9H_{20}	0.740	136	7,900
Nonane, normal	C_9H_{20}	0.722	150	
Decane	$C_{10}H_{22}$	0.738	160	8,060
Benzine	C_6H_6	0.884	80.4	9,690
Teulene	C_7H_8	0.871	111	

If the evaporation is noted and the difference in weight is observed at fixed intervals of time, the curve will show the several rates of evaporation and it will be possible to approximate the percentages of the more volatile fractions in comparisons with the heavier contents. Butane, for illustration, would disappear so rapidly as to make its measurement difficult. This fraction boils off violently at the normal temperature of the surrounding, and pentane boils "on a cake of ice." Hexane, on the other hand, boils at what may begarded as the temperature of the surrounding, and it is therefore the natural fuel for use in automobile motors, particularly since the calorific value of this fraction is but slightly below that of the heavier fractions. The illustration, Fig. 4, is offered merely as a suggestion, with the idea of elucidating the principle, taking into account relative evaporation under normal conditions. The question of the "heat exchange" will be taken up also, especially since this is a phase of the situation that bears heavily upon the subject.

Considering fuel of this sort, in carbureters, in the conventional way, it is true that water-jacketing will go a long way toward vaporizing the gasoline, and even preheating the air en route to the carbureter will avail much. On the other hand, if the fuel is of the most non-volatile sort. as it may be, it is then that the gasoline will enter the cylinders in globule form, to some extent, at any rate, as depicted in Fig. 5, in which the globules are shown enlarged as they emerge from the carbureter, and since evaporation goes on all the time, and at a rapid rate, if the heat is there to excite the same, the globules will diminish in size as they traverse the manifold, so that the more heat there is available and the longer the manifold the greater is the chance of realizing the much-desired vaporized condition of the fuel by the time it enters the cylinders.

On the other hand, the amount of heat utilized for the purpose should be minimized, on the ground that the weight of fuel in acceptable form will be decreased if the heat is in excess of the exact requirement. That the power realized from a motor will be a maximum if the gasoline is in the most acceptable form is too plain to require further discussion, but there are other phases of the subject that can well monopolize space.

Influence of Fuel on Cranking the Motor.—In kerosene and alcohol motors the question of starting is probably the most important detail, and the greatest bar to the use of both of these classes of fuel. In automobile motors, considering "automobile gasoline," which is not nearly so volatile as real gasoline, this same question comes up, and it is becoming more important as the grade of gasoline is decreasing, from the point of view of volatility. With perfected motors, as they are now to be had, cranking would be with almost no trouble at all were gasoline

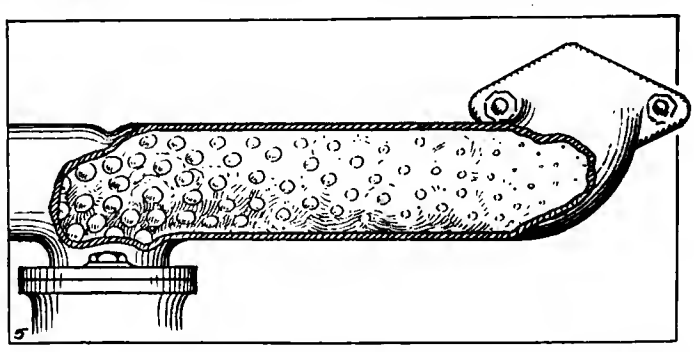


Fig. 5—Depicting the reducing sizes of globules for increasing length of the manifold.

of some grade as "hexane." Even as it is, if a large percentage of the gasoline is of the more volatile fractions, the cranking question is devoid of much difficulty, provided a means is at hand for flooding the carbureter, in order to assure that enough of the more volatile fuel will spill out on the "pan" to satisfy the conditions. Fig. 6 is offered with a view to showing the manner in which "priming" affords relief from the ills of fuel; a large part of which is so non-volatile that it will not vaporize until it contacts with the heated cylinder walls.

The object in priming is to spill out so much fuel that enough of the more volatile fraction will be available to enable the motor to be started. Once the motor starts and the cylinder walls are heated, the less volatile fuel will burn in any case when it enters the cylinders, unless it is that a portion of the fuel breaks down and forms coke. Between the most volatile portions of the fuel (which are the superior fractions to use in cranking) and the heavy fractions there is, of course, a range of fuel that will vaporize in the intake before it enters the cylinder, once the motor is warmed up and the heat is communicated to the surrounding parts. The construction, Fig. 6, is intended to show the manner in which the gasoline raises in the depression chamber "pan" as the result of priming, although it will be understood that there are many ways of constructing carbureters to attain the desired results. In this case the gasoline raises in the depression chamber of the carbureter, and the more volatile portion is picked up by the cold air as it enters the air passage when the motor is being cranked, due to the displacement of the pistons in the motor cylinders and the resultant inrush of air in the intake of the carbureter.

When the motor starts, the float or equivalent device takes charge, and in a few minutes the level of the gasoline falls away to the normal, due to the controlling action of the float. If the gasoline is of a good quality there is danger of flooding, so called, due to the volatility of all the excess gasoline in the pan, and since there is vastly more than is required for the normal operation of the motor, if it is volatile the mixture will be enriched in excess of the requirement. This trouble is disappearing, due to the lack of volatility of automobile gasoline as compared with gasoline proper, and in modern carbureters it is the practice to adequately provide for starting: (a) by so designing the depression chamber that the partial vacuum formed will be a maximum, and (b) so contriving that the flooding process will be effective. As soon as the motor starts, the auxiliary air passage is adjusted to afford an adequate volume of air, in order that the mixture will be the most efficient for the purpose, and, as before stated, when the amount of gasoline is about 1.9 per cent. vapor to air, the best results will be realized. It is not difficult to attain the best result for the reason that the auxiliary air valve will afford a wide range of adjustments, and the motorist soon attains a degree of skill which enables him to judge of the requirements.

Effect of Evaporation on Temperature.—When gasoline evaporates the temperature of the liquid is lowered, and the amount of the change depends upon the proportion of the fractions in the fuel, due to the differences in this respect between them. The drop in temperature for the respective fractions will be as follows:

EFFECT OF EVAPORATION ON TEMPERATURE OF REMAINING LIQUID.

Hexane.	Heptane.	Octane.	Decane.
19	17.9	17.2	14.8

The drop in temperature as above given is in degrees centigrade, assuming that the exact right amount of air is intimately mixed with the fuel in the process of evaporation, and on the further assumption that the fuel is not allowed to change in temperature at the expense of some outside source of heat. On the other hand, to assure this performance it is necessary to consider that the air has to be at a certain temperature at the time of contact with the gasoline. The minimum temperature will be:

MINIMUM TEMPERATURE OF THE AIR FOR A GIVEN TEMPERATURE CHANGE.

Hexane.	Heptane.	Octane.	Decane.
1.3	21.5	36.2	56.8

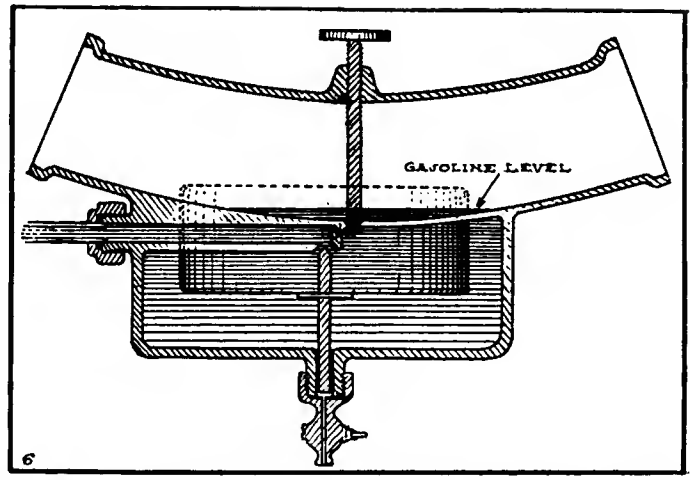

Fig. 6—Showing the accumulation of gasoline in the pan of the depression chamber, as the result of priming.

These values will depend upon the conditions as above set down, and in this case the temperature is in degrees centigrade also. There is one other point to be taken into account, *i. e.*: There is a minimum temperature at which a vapor can be supported, and this temperature will be different for each fraction, measured at the atmospheric pressure. This minimum temperature is given as follows:

MINIMUM TEMPERATURE AT WHICH FUEL WILL VAPORIZE.

Hexane.	Heptane.	Octane.	Decane.
—17.7	3.6	19.0	42.0

in which the temperature is in degrees centigrade. This tabulation is of the greatest importance, in that it indicates indirectly, to be sure, the relative vapor tensions of the several fractions of the hydrocarbons in common use in automobile gasoline. What will be the resultant of combinations of these fractions in practice is, of course, a speculation, and, too, account must be taken of the better performance of automobile gasoline when the air is in excess, rather than in the theoretical right amount.

In practice it is the custom to adjust the auxiliary air valve of the carbureter until the best result is realized, and it is common custom to consider that the air is in excess about 30 per cent. when the fuel is doing the best work. As to whether or not 30 per cent. is a good estimate must depend largely upon the motor in any given case, for, as has been demonstrated on many occasions, a carbureter that seems to do good work on one motor fails to work in a manner to be commended in another case, considering two motors of the same size. It does not follow that one of the motors will deliver more power than the other, although it might be possible, and it would be the height of good practice to look for more power from the motor using the least fuel under these conditions. It is certain that the thermal efficiency would be the highest for the motor that would work on a given (minimum fuel) carbureter adjustment, and in all probability the difference is to be found in the degrees of scavenging of the respective motors to a vast extent, at any rate.

Irrespective of the relative performance of motors it is necessary to supply an excess of air to all, the exact excess depending upon the quality of the motor in each case, and while the subject is up it is to say quality resides in a motor that uses fuel efficiently, and it is also true, very likely, that the motor requiring the least excess of air for a given fuel consumption is the superior motor to use. In the various types of motors available this excess air requirement is all the way from 20 to 60 per cent., with a few examples perhaps in which the excess air is below the low figure mentioned.

In view of the nitrogen content in mixtures, there is no actual need of any further dilution with a view to rendering the mixture slow burning. It will be understood that nitrogen serves a useful purpose, in that it renders the mixture sufficiently slow burning so that it can be used. Were the fuel free from nitrogen

and sufficiently supplied with oxygen in the right (excess) ratio, under the conditions of compression as they now obtain in motor cylinders, it is not believed that cast iron would hold together long enough to complete one revolution of the crankshaft after the event. The event would be what is commonly termed a disruptive explosion, and the force of the blow would do much damage.

With the minimum sufficient amount of air, considering a pound of gasoline, the products of combustion would be as follows:

PRODUCTS OF GASOLINE COMBUSTION PER POUND OF GASOLINE.

Carbon Dioxide.	Water Vapor.	Nitrogen.
2 pounds.	1.5 pounds.	11.8 pounds.

In this is evidence of the presence of 15.3 pounds of air per pound of gasoline, and, while the ratio will change under different conditions of fuel, the nitrogen content is the major portion. That this large volume or weight of nitrogen is necessary may be more or less true, but it is not necessary to include a considerable percentage of spent product of combustion in the bargain, hence the desire for the most perfect possible conditions of scavenging, or further additions of air in the absence of perfect scavenging. With imperfect scavenging more air is needed, for the reason that all the oxygen enmeshed in spent products of combustion is lost for the real purpose, and to whatever extent this process is represented additional air must be supplied.

Excess air in the mixture will upset the conditions involved in the temperatures, both of evaporation and of the air before evaporation. Increasing the air excess has the effect of decreasing the temperature drop, as would be natural, since the specific heat of the air is substantially constant, and the heat units involved will be proportional to the weight of air taken, which, in this case, for 30 per cent. more air than the net requirement, will be as follows:

EFFECT OF EVAPORATION ON TEMPERATURE OF REMAINING LIQUID.

Hexane.	Heptane.	Octane.	Decane.
15.2	13.9	13.3	11.5

In this, as in the preceding case, it is assumed that the liquid is not affected by heat additions from any outside source, and the temperature in degrees centigrade is that due to the heat exchange, pure and simple. In this, as in the preceding case, it is also necessary to take into account the minimum temperature at which the air will have to exist, in view of the results given for the fall of temperature in the liquid on a basis of 30 per cent. excess air, which air temperature will be as follows:

MINIMUM TEMPERATURE OF THE AIR FOR A GIVEN TEMPERATURE CHANGE.

Hexane.	Pentane.	Octane.	Decane.
—7.1	13.2	27.8	49.2

Likewise, increasing the amount of air to excess over and above the net requirements for theoretical complete combustion influences the temperature at which the fuel can support vapor as follows:

MINIMUM TEMPERATURE AT WHICH FUEL WILL VAPORIZE.

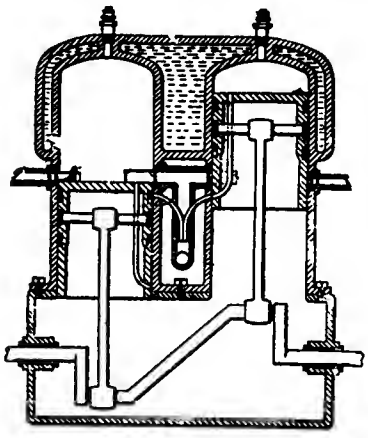
Hexane.	Pentane.	Octane.	Decane.
—22.4	.5	14.5	37.7

Increasing the air content has the effect of lowering the temperature at which the gasoline will vaporize, and, as will readily be understood, this is one of the reasons why excess of air is by way of decreased trouble in practical operation.

(To be continued.)

HOW TWO-CYCLE EFFICIENCY IS INCREASED.

A new feature for application to two-cycle engines has been made the basis of letters patent by its inventor, Manuel S. Carmona, of Mexico City. One drawback of the two-cycle motor has been the poor efficiency of the exhaust stroke, this working out in two ways, one the exhaust gases left in the cylinder vitiate part of the mixture, and the other, the incoming fuel is used to blow the exhaust out, some of it following, thus reducing the fuel economy. This new idea is applicable to any two-cylinder motor with cranks at 180 degrees or any four cylinder with adjacent cranks at 180 degrees. It consists primarily (as shown in the cut), of an extremely small diameter tube set into the piston in such a manner that at the point of maximum compression in that cylinder, its lower end will register with a similar sized tube set into the cylinder wall and communicating with the pipe into which the adjacent cylinder is exhausting.



Cross Section Carmona Motor.

The idea of this is that a very small portion of the gases at compression pressure escaping into the exhaust pipe will create an injector effect or vacuum which will clear the cylinder of spent gases more quickly than otherwise.

GEORGIA CITIES USING TAXICABS.

SAVANNAH, GA., April 19.—The hackmen in the State of Georgia are becoming alarmed these days because most every city has, or is going to use, taxicabs in a very short time. The latest to fall in line is Macon.

TAXICABS IN PLENTY FOR THE HOOSIERS.

INDIANAPOLIS, IND., April 12.—Although there are no cabs now operating in the city, within sixty days there will be three separate lines working, with some twenty or thirty cabs on the job.

John E. Morand, interested in the Frank Bird Transfer Company and the Indianapolis Transfer Company, has placed an order with the Coppock company for ten vehicles, which will be placed at the Union Station and in front of the principal hotels.

The first company to get into action will be Charles W. Sheetes & Son, for whom the Lambert company has practically completed four taxicabs. These will be delivered and in use by the first of May.

The Overland company is now manufacturing taxicabs, of which some ten of the first lot have been ordered and are eagerly awaited by a local company.

From all appearances, it will not be long before many of these cabs will be in service, and from the interest that is being displayed in them it seems as if Indianapolis will be a red hot taxicab town.

MOTOR TRUCKS NOW BARRED FROM DOCKS.

NEW YORK CITY, April 19.—The work of years in gradually winning the various steamship lines over to a sane view of motor trucks has been upset in a minute by the action of the New York Fire Insurance Exchange, which recently notified the owners of all docks that if gasoline or steam trucks were allowed on the piers they would increase the insurance rates 50 cents per $100. As this is a 50 per cent. increase, the dock owners at once prohibited all vehicles using gasoline, kerosene, benzine or naphtha from going on the piers. Following this drastic action the New York Automobile Trade Association, the Association of Licensed Automobile Manufacturers and the American Motor Car Manufacturers' Association announced their intention of fighting for a more liberal attitude, which will place the self-propelled vehicle on a par with horse-drawn trucks. Having worked for years to obtain this privilege, they do not propose to lose it without a struggle.

Repair of Aluminum Castings by Oxy-Acetylene

By Henry Cave

PROBABLY the most radical development produced by the advent of the oxy-acetylene flame is the welding of aluminum. As most people are probably aware, all other metals are amenable to some form of brazing or soldering process. Cast iron could have been considered in the same class as aluminum until a few years ago, when discoveries were made resulting in it being possible to braze it more or less satisfactorily. Aluminum, however, defied all attempts to unite it in a manner which would in any way approximate the strength of the metal. Though

Badly Broken Case Prepared for the Welding.

it has for several years been possible to solder it, the results are not satisfactory where anything more than the stopping of a leak or other requirements as would not subject the joint to strain. Even for this purpose it requires considerable experience to get satisfactory results, and the permanency is always doubtful, owing to the possibility of electrolytic action. The reason of this difficulty is that metallic aluminum always contains a small amount of oxide, and therefore it is extremely difficult to coat the surface without having an intervening layer.

Even though a neutral flame (or the flame can even be adjusted to contain a surplus of carbon) is obtained with the oxy-acetylene torch, the molten surface of the aluminum being fused by this means has a coating of oxide which has to be broken up by puddling with a steel rod, allowing the metal to run together, thus producing a weld that is practically local recasting. It has often been attempted to remove the oxide chemically by means of a flux, but so far this has not been accomplished, though certain chemicals have been found that help considerably and add to the strength and smoothness of the weld.

It is interesting to note that, though the oxy-acetylene welding process originated in France, and is much more extensively used there than in this country, we are considerably ahead of them in the art of welding aluminum.

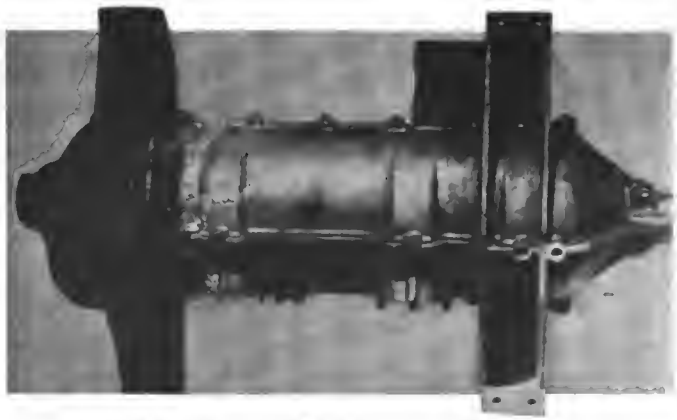
Though aluminum fuses at a comparatively low temperature (1,200° Fahr.), its high conductivity for heat, which has a ratio of 31.3 as compared with 11.9 for iron, makes it necessary to use more heat in welding than is required by metals having a much higher melting point. The heat being conducted away from the weld into the surrounding metal to such an extent that when the surface to be welded becomes molten the metal for a considerable distance around is close to the point of fusion and liable to collapse if great care is not exercised. This is often guarded against by placing what is practically a complete mold under the part to be welded. The first illustration above shows this in practice, the clamp being used to hold the mold.

It can be readily seen that one of the principal features of carrying out this work is the time taken, as the longer the flame takes to fuse the metal, the greater the amount of heat that is conducted into the surrounding parts; therefore, the hotter the flame, the less the time and the conduction of heat. This is the reason why it is necessary to use a flame of such a high temperature (6,300° Fahr.) as that produced by burning acetylene with oxygen to obtain satisfactory results on a metal of such a low point of fusion, as aluminum.

Another feature is helped by confining the heat to as small a space as possible by reducing the time for conduction, as this also reduces the expansion. The chance of the part cracking, due to the shrinkage of the metal in cooling is considerably reduced. The chance of cracking can be realized when it is known that the shrinkage of aluminum in cooling, from the point of fusion to atmospheric temperature, is three-sixteenths of an inch per foot. The modulus of elasticity of aluminum as given in textbooks is 11,500,000 lbs. per square inch. This is a theoretical figure that represents the weight per square inch that would be required to stretch a piece of the material to double its length. if the elasticity remained the same as it is up to the point where it actually ceases and commences to tear the metal apart.

Tensile tests of aluminum alloy, as used for automobile parts, generally show that the elastic limit and maximum strength practically coincide, the material not having any appreciable elongation, and this elongation is reduced to a vanishing point when the metal is heated to a few hundred degrees.

Taking an example of shrinkage in two inches, which is no uncommon length to have molten at one time, using the above figures, then the stress produced would be $\frac{11{,}500{,}000}{1/32 \times 2}$, or 718,800 lbs. per square inch, which is far more than any metal could withstand, and if it is not ductile enough to stretch, it would certainly pull part. This trouble is, however, eliminated in most cases by preheating the part to be welded, uniformly all over, and in this way reducing the extreme difference in temperature, and therefore the contraction between the metal at the weld and



This Case Was Nearly Severed, But Welding Saved It.

the rest of the casting. That is, the parts that otherwise would tend to hold the weld from contracting in cooling will themselves have to contract at the same time as the weld, thus practically eliminating the strain. It can readily be seen that it is not necessary to preheat the part when a foot or lug is broken off entirely, as there is nothing to restrict the contraction.

Castings having a thin part connected across parallel to a

Both Halves of Case on Which Fourteen Welds Were Made.

heavy section are practically impossible to weld with the present development of the process, though it is quite possible that means of doing this may be discovered any time. There is, of course, some difference in the action of the different alloys now being used, and what might prove a failure in one case might be a success with other material.

Up to the present time the new aluminum alloy, "Magnalium," which is coming into use, cannot be satisfactorily welded, due to a very heavy oxide forming on the surface, but a flux may sooner or later be discovered to eliminate this.

A few pictures showing work of this class are given on this page. They represent cases of entirely broken parts, those only cracked and instances where it was necessary to build up additional metal. Fig. 1 is a badly broken case prepared for welding with the mold and charcoal in place. Fig. 2 shows a lower half of a crankcase, which was nearly severed at one point. The third figure is a transmission case which necessitated welding in no less than fourteen places, as indicated by the small arrows. In the center of the figure, *A* shows where the metal was built up to form a new lug in place of one broken off and lost.

AMONG THE NEW AUTOMOBILE BOOKS.

The Gas Engine.—This 447-page work is an attempt to cover the whole of the field. The author, Forrest R. Jones, formerly an instructor at Cornell, and more recently at the head of the New York School of Automobile Engineers, has treated the subject in a manner that renders it more of a text-book than a reference work. The general order of the subject matter is as follows: Descriptive, operative, testing for faults, theoretical, results of tests. The very important subject of ignition is well covered, no less than 52 pages being devoted to it. The chapters on cooling, lubrication and exhausting are very brief, almost too much so. A short but very practical treatise on valve timing is followed by a number of pages on troubles and tests. A brief portion at the end of the book is given up to the pure theory of the heat cycles, which are well, if briefly, covered. The whole book is written in exceedingly plain language, the extremely technical being purposely avoided. This is a feature that will gain it many friends among the non-technical readers. The book is published by John Wiley & Sons, of New York City, and the retail price is $4.

"Automobiles."—This is the text-book of the American School of Correspondence, located in Chicago, and consequently its 186 pages are rather elemental. The author, Hugo Deimer, M. E., is professor of mechanical engineering at Pennsylvania State College. The book is called a practical treatise on the construction, operation and care of gasoline, steam and electric motor cars, including mechanical details of running gear, power plant, body and accessories, instruction in driving, etc. The subject matter is divided into five chapters and copiously illustrated with cuts of American cars and parts of cars, very few line drawings being used. Considering its audience, the book has been carefully freed from any and all traces of theoretical or technical matter; in fact, it is of an intensely practical nature.

THE AUTOMOBILE CALENDAR.

AMERICAN.

Races, Hill Climbs, Etc.

April 22-24.....Chattanooga, Tenn., Hill Climb on Lookout Mountain, Lookout Mountain Automobile Club.
April 23-25.....Denver, Col., Dealers' Demonstrating Tour, to Pueblo and return.
April 24.....Philadelphia, Roadability Run to Atlantic City, Quaker City Motor Club.
April 26-May 1...New York City, Second Annual Automobile Carnival, New York Automobile Trade Association.
April 26.....New York City, Second Annual Hill Climb, Fort George-New York Automobile Trade Association.
April 26-28.....Lawrence, Kan., Three-Day Endurance Run, Lawrence Automobile Club, Beatrice, Lincoln, Fairbury, Lawrence.
April 28-30.....Pittsburg, Pa., Gazette Times-Chronicle Telegraph Three-Day Endurance Run. Indorsed by Automobile Dealers' Association.
April 30.....New York City, Endurance Run, New York Automobile Trade Association.
May 3-6.....Harrisburg, Pa., Third Annual Endurance Run, 700 miles, Washington, Baltimore, Scranton, Motor Club of Harrisburg.
May 10-13.....Detroit, Mich., Four-Day Endurance Run, Detroit Automobile Dealers' Association.
May 18-19.....Norristown, Pa., Second Annual Endurance Run, Norristown Automobile Club, to Hagerstown, Md.
May 22.....Hartford, Conn., 200-Mile Endurance Run, Hartford Automobile Club.
May 22.....Newark, N. J., Third Annual Endurance Contest, New Jersey Automobile and Motor Club, 190 Miles.

Letters Interesting and Instructive

NAPHTHALENE INTERESTING.

Editor THE AUTOMOBILE:

[1,843.]—Will you please inform me where naphthalene can be procured and at what price? How is it used as a car fuel and can it be used in common runabouts?
A SUBSCRIBER.
Griffin Corners, Delaware County, N. Y.

Naphthalene is put on the market in three forms: flake, balls and crystals. These may be obtained from any wholesale druggist. The retail price cannot be given, but it will not be far from 3 cents per pound, as the wholesale price is 2½ cents. This is for all grades, but the first and last would be the most pure and, therefore, by far the most desirable.

To use it as a car fuel will require special apparatus: first, to melt it; second, to heat and vaporize the resultant liquid, and third, means for feeding the vapor to the engine as required. Aside from melting it, the process of using it will be exactly similar to the use of alcohol as an automobile fuel. Gasoline weighs a little over 6 pounds per gallon, so that at 18 cents per gallon the price per pound is about 3 cents. This gives a basis of comparison, but not very favorable to naphthalene. In France it costs 12½ cents per pound, while gasoline is 65 cents per gallon. This makes the latter cost about 10½ cents. Even at these apparently unfavorable prices, it appears that the motor uses less of the naphthalene fuel than of the gasoline. On the Paris-Versailles test, spoken of in the March 25 issue of THE AUTOMOBILE, the cost of fuel using gasoline only was $2.75, while the other cost but $0.82, with $0.22 added for gasoline used in starting. Apparently more tests are desirable.

AUTO RAILWAY CAR.

Editor THE AUTOMOBILE:

[1,844.]—I understand that there are some attachments made for use in running an automobile on railroad tracks. Will you kindly give me addresses of all the different makers of these attachments? H. E. H.
Princeton, W. Va.

About the only attachments necessary for cars of standard gauge are a means of locking the steering gear and railway wheels with the proper flanges. If the car is not of standard gauge, some sort of shims or washers will be needed to bring the gauge (tread of the automobile) up to or down to standard railway gauge. As to flanged wheels, you being a railway man, should know of more manufacturers than we do. Simply order them with plain hubs and bore the hubs out to suit your axles. We have never heard of a manufacturer of a steering gear lock for this purpose, but you can render the gear ineffective by taking off the cross connection back of the axle and the steering rod from the right knuckle to the moving arm of the gear.

It is not advisable to use an automobile in this manner, as it throws upon the springs and other running gear parts undue strains which they were never designed nor intended for. Ball bearings in the wheels, for instance, would not stand up very long under the pounding of uneven rail ends, nor would any hardened bearings.

INCREASING THE COMPRESSION.

Editor THE AUTOMOBILE:

[1,845.]—In case it is desirable to increase the compression in a cylinder, is it practicable to do so without recasting the whole cylinder? I refer to two cycle engines where it would be impossible to use plates on top of the piston. If you will give me the details of the best method to accomplish this result, I would appreciate it.
New York City. INCREASE.

There are four ways in which the compression of a two-cycle engine can be changed, and there seems to be some drawback to the use of nearly all of them. In case your engine has a separate cylinder head, held on by bolts, the upper part of the combustion chamber of this can be "fattened up" with some form of plate or any other means which will decrease the size of the chamber. In case your cylinders are not so made, this process will not be an easy one.

Then the second method could be tried. In case the cylinder casting is bolted to the crankcase, take the cylinder to a machine shop and have an ⅛ inch or the desired amount turned off of the lower face.

In place of this you can get a new connecting rod with the hole for the piston pin raised above the height of the present one by the desired ⅛ inch, that is, get a rod ⅛ inch longer.

The last resort will be a new piston with the hole for the piston pin bored lower than standard by the amount desired.

The only drawback to the first method is the work connected with it, particularly to do a nice job. In the case of the last three, however, the changes all alter the action of the piston in uncovering the ports in the cylinder walls, and with it the action of the cycle. That is, the piston would not uncover the inlet and exhaust ports at the same time in the stroke as at present, and possibly might not uncover them at all. This alteration of the cycle would probably eliminate some, if not all, of the power of the engine, and in any case would alter it greatly.

Summing up the advantages and disadvantages, unless your engine is so constructed as to allow of readily decreasing the combustion chamber volume as per the first method, it would not be advisable to try to change it. In any case, confer with the manufacturer before going ahead.

PROPER VALVE TIMING.

Editor THE AUTOMOBILE:

[1,846.]—Will you please give me some idea of the proper valve timing? My engine does not run very well and I am thinking of changing the valve setting. R. B. JOY.
Buffalo, N. Y.

In an article in THE AUTOMOBILE, October 29, 1908, the subject of valve timing was exhaustively treated. In that article figures were given for a number of prominent French engines. The average valve timing for the 31 engines was as follows: Inlet opens 8° 6′ past the upper center, inlet closes 26° 15′ past the lower center, exhaust opens 46° 20′ before the lower dead center and closes 5° 40′ beyond the upper center.

You do not mention what your trouble is or we might be able to offer some advice. In any case it is not advisable to tinker with as important a matter as this without first consulting the manufacturer. It is barely possible that your camshaft has been put in place one tooth out of the correct position. This would effect the whole cycle very materially, so it would be advisable to look at the gears and see if they are not marked at the point of correct meshing.

FLAT VALVES AND SPEED.

Editor THE AUTOMOBILE:

[1,847.]—Will you please answer the following questions in your "Letters" columns:
(1) When and by whom were the following originated: transmission on the rear axle, underslung frame, valves in the head.
(2) What American cars use flat seated valves.
(3) Did an eight-cylinder motor cycle ever do 120 miles per hour as has been claimed?
St. Paul, Minn. L. G.

It would be a hard matter to give an exact answer to all of your questions, thus it is impossible to say who was the originator of all automobile parts. De Dion was one of the very early users of transmission placed on the rear axle, this being in 1899. Valves in the head were first used by Diesel. We do not know who first used the underslung frame.

(2) Locomobile uses flat-seated valves for the inlet on the 40-horsepower car. Hewitt also uses them on his trucks. The manufacturers of the Jencick motors, employed mostly in motor boats, use flat seats. These are about all of the American cars using them. This type is more favored on the other side, as in England, James & Browne, Humber, Brush, Wilson-Pilcher, and some of the Napier output are so equipped. Fiat is a prominent advocate of this construction.

(3) We have never heard of this claim nor of any speed trials or races which would substantiate it. In "The Automobile" for February 25, 1909, you will find the following, relative to motor cycle time: "The fastest time recorded as having been

made on a motor cycle is that of a mile in 44 2/5 seconds, a speed of 81.08 miles per hour, by William Wray on an imported Peugeot machine. This is not recognized by the F. A. M. as a record, because the engine was rated at 14 horsepower. The record for a straightaway is 46 2/5 seconds, a speed of 77.58 miles per hour, made by G. H. Curtiss, on a Curtiss. The circular track record is 54 seconds, a speed of 66.66 miles per hour, held by Fred Huyck, riding an Indian." As a speed of 120 miles per hour would mean a single mile in 30 seconds, you can see thus far it has not even been closely approached.

WANTS TO DYE.

Editor THE AUTOMOBILE:

[1,848.]—Will you please tell me what to use to color a canvas top black, something that will not fade and will stand weather conditions. S. L. D.
High Point, N. C.

The best substance to use is boiled oil, which you can obtain anywhere. This is applied with a brush or in any handy manner. To color this, add the color pigment until the desired shade is obtained, stirring the mixture very thoroughly. Apply this to the top in a series of coats, the first of pure oil only, the others of pure oil or the colored mixture, as desired. These should bear some relation to the numher of coats which you wish to put on. Any number may be used, but beyond four the total coating becomes rather thick and therefore more liable to crack. Up to four, however, you are safe, and this number will shed water perfectly. With four coats, only the last needs to be colored, that is three coats of oil and a final coat of colored oil. If you have no fear of cracking, you can use as many coats as you desire to, the waterproofing effect increasing with the increase in the number of coats.

PECULIAR MISFIRING.

Editor THE AUTOMOBILE:

[1,849.]—Will you please explain to me the cause of my engine missing? It is a four-cylinder machine of a popular make and not over two years old. The valves have all been ground in very recently and the seats are O. K., the plugs have been carefully examined and are also all right, the cylinders all fire and apparently fire in proper order and at the proper time. Yet in spite of all this the engine misses, particularly at high speeds. On low speeds and at starting it runs fine as well as anyone should ask, but as soon as I speed up it begins to miss.
Rochester, N. Y. X. Y. Z.

Your trouble is apparently in a sticking valve stem or stems. Take out the valves one at a time, and see if the stems have become gummed with oil. In fact, if this is the only trouble, it will not be necessary to take them out, but just squirt kerosene on the stems. In case it is not a matter of gumming, you will have to ascertain if the stems are straight. You can do this by rolling the stem portion on a surface plate, when any deviation from a straight and true shape will show itself. The valve stem may be out of round, which the rolling process will also disclose. Having corrected these sources of trouble, if the engine does not run as it should, look to the valve guides in the cylinder. They must not only be clean, straight and round, but at right angles to the plane of the seat.

The trouble of missing with correct ignition and tight valves is made apparent in the missing at high speeds. If the valve sticks, a sufficient charge will be drawn in, but the valve will not close, due to some of the causes we have mentioned, and the compression stroke will blow the charge out again. At slow speeds, the valve spring has a measurable time in which to act, so the effect is less, but as the motor speeds up this time becomes less and less, so the final result is that the whole charge is blown out or such a large proportion of it that there is not enough left to ignite. As a result, the engine misses, and will continue to miss until the valve stems have been properly attended to.

WANTS TO MAKE GASOLINE.

Editor THE AUTOMOBILE:

[1,850.]—Will you please tell me what apparatus is necessary and what will be the process for making gasoline from natural gas? Would such a process be liable to be commercially successful? H. McGREGOR.
Harper's Ferry, W. Va.

Going into the chemistry of the matter, we find that natural gas, like many of our other fuels, is a compound, the principal constituents being hydrocarbons. These are themselves compounds, and are grouped broadly into two classes, the paraffins and the olefines. If a heavy hydrocarbon of the paraffin series be exposed to heat while under pressure it will be decomposed into a lower hydrocarbon and an olefine.

For instance $C_{12}H_{26}$ is decomposed into hexane C_6H_{14} and the olefine, hexylene, C_6H_{12}. In a similar manner, the reaction may be continued until the highest member of the series and the most desirable from a fuel standpoint, methane, CH_4, is obtained. The normal composition of natural gas is such that 93 per cent. of it is hydrocarbon. Gasoline being a hydrocarbon it is possible by means of heat and pressure suitably applied to produce it as the ultimate result. It is possible, but not very probable, and the whole matter should be looked upon rather in the light of a laboratory "stunt" than of any practical value.

The same line of reasoning has been applied to the production of alcohol from natural gas, this being given the preference over gasoline, for the reason that the present market price of alcohol is about twice that of gasoline, and thus there is a chance of the process being commercially successful.

MORE ABOUT TOWING CONTESTS.

Editor THE AUTOMOBILE:

[1,851.]—In the April 1 issue of "The Automobile," in Letters Interesting and Instructive, H. M. Conroy asks: "Wherein would the motor be tested, in a coasting contest with the clutch disengaged." It would not, and that is one of the things to be desired. Many a good motor is badly abused by having to propel a lot of junk. Most every rig has one or more places where power is being wasted, and the motor gets the blame. A dragging brake band causes overheating. Does the user fix the band? No! He gets a larger pump or gears the fan faster or puts on more radiator. He does not know any better. The coasting or towing contest would tell him better. It is true that there are tricks to all contests and that a contest proves little or nothing. But there is just as much trickery about a contest up hill as there can be about one down hill. If the honor of the contestants cannot be trusted (I believe it usually can be) then appoint investigating committees who will see that the rigs are in operative condition. Or put the winning rigs through a road test immediately after winning.

I have for years believed that every owner should know about how much it takes to move his rig on the garage floor. Either he should have a spring balance handy and tow it or he should push it often enough to know when it is pushing freely, and when there is something wrong that needs looking into.

I send photo showing a Buggyaut being towed. I have rigged on this a large scale so that the actual pull can be easily photographed. A cycle air tube forms the spring. A standard spring scale is also used to be certain the results are correct. Such a large scale could be easily used in a towing contest, and the public could see the actual pull for themselves. An asphalt street, and no wind, is all that is needed. These tests ought to be very common. They would add a lot to the improvement of the auto.

Mr. C.'s suggestion that a flexible motor is much to be desired is certainly correct. This can be gotten at by taking the slowest high speed on a hill and the fastest high speed time of the same rig.

CHARLES E. DURYEA.

Duryea Car Rigged with a Spring Balance to Measure the Pull Required to Move It.

CONCERNING AIR-COOLING AS OPPOSED TO WATER-COOLING

By ARTHUR HOLMES, First Assistant Engineer H. H. Franklin Mfg. Co.

IN THE AUTOMOBILE, March 18, appeared "Automobile Cooling Systems Analyzed," by Morris A. Hall, relative to the comparative efficiencies of air-cooled and water-cooled automobile motors. In this occurred several statements, evidently made without sufficient reflection.

After giving the reasons for cooling the cylinder walls of an internal-combustion motor—which, by the way, are undoubtedly correct—he quotes from the Franklin catalog relative to the cylinder wall temperature at which a gasoline motor does its best work. He then goes on to say that this temperature is entirely too high because, although he admits the thermal efficiency at such a temperature is indeed very high, the mechanical efficiency would be lowered correspondingly so that the net result or B.H.P. would remain the same.

Mr. Hall right here lays himself open to very serious criticism, for he forgets that it is the practically universal custom to compare the performances of gasoline engines by B.H.P. This, of course, takes into account the mechanical efficiency. For instance, suppose we had two engines of identically the same bore and stroke, the general design of bearings, etc., the same, one of these engines, however, being water-cooled and the other air-cooled. Suppose, then, these two engines were put on the block and tests for economy were run off. Inasmuch as it is impossible at the present date to accurately indicate the horsepower of a high-speed gas engine, it would be necessary to base these economy tests on the B.H.P. delivered by each motor.

Mr. Hall in his article makes use of a heat balance taken from a well-known authority (we think we have seen it in Dugald Clerk's book, "The Gas and Oil Engine"), in which the I.H.P. is given as 17 per cent. of the total heat units contained in the fuel. This is undoubtedly a very good example of what a water-cooled motor should do, and from the present writer's experience the B.H.P. seldom attains this figure.

We are safe, then, in assuming that the water-cooled motor which we are testing would do no better. On the other hand, however, the air-cooled motor would develop its power with an efficiency, calculated in the same way, of 19½ per cent. This can be verified by the authorities at Sibley College, Cornell University, under whose direction many such tests have been run off on a Franklin motor in the laboratory of that institution. This would mean that if these motors of the same horsepower were put into two identical cars and run over identically the same roads in the same way, the water-cooled car would use 14.1 per cent. more gasoline than the air-cooled car. Of course, it would be impossible to put these two engines in exactly the same cars, for Mr. Hall says "the more bulky, assuredly heavier, and admittedly more complicated fluid systems with positive circulation."

We have proved to ourselves and others, by such tests, that air-cooling does raise the heat efficiency based on the B.H.P., regardless of whether this rise is due to a great rise in thermal efficiency proper, accompanied by a smaller loss in mechanical efficiency, or by not quite so great a rise in thermal efficiency and no change in mechanical efficiency.

The mechanical efficiency is, of course, the ratio of the power delivered by and outside of the engine to the power developed inside the cylinders. This term is made necessary because of the fact that some of the power developed inside the cylinder is lost as far as useful work is concerned, in friction, due to the pistons working in the cylinders, the connecting rod and crankshaft bearings, the camshaft gearing, etc. In fact, wherever any mechanical motion occurs power is lost, due to friction. It is with this loss in friction in the engine parts which we have now to do. As Mr. Hall says, one of the chief reasons for cooling cylinder walls is to insure proper lubrication: he might very well have said, then, as far as lubrication is concerned it is unnecessary to cool the cylinders as long as they are perfectly lubricated. In other words, cooling, from a lubrication point of view, is merely a relative term depending entirely upon the nature of the lubricant.

We have no tests at hand showing the friction losses in motors running perfectly cool and others running at the temperatures attained by air-cooled motors, nor do we know any; but we do know that in general the friction generated between two surfaces is dependent upon their lubrication, and not upon temperature.

Quoting from Unwin, an efficient lubricant should possess the following qualities:

(a) It should wet the rubbing surfaces.
(b) It must not evaporate or decompose while in use.
(c) At the temperature at which it is employed it should have enough, and only enough, viscosity to remain between the surfaces.
(d) It must contain no acids or other constituents capable of acting on the rubbing surfaces.
(e) It must be free from grit or other foreign matter.

From the above it can readily be seen that the only qualification having any bearing on the case in question is that the lubricant should be correct for the temperature at which it is used. Now there are many lubricants which can stand a temperature of 350°, so the lubrication question is very easily solved. In fact, it is far easier than in many cases in so-called ordinary steam engineering which may have escaped Mr. Hall's attention. We refer now to engines using superheated steam or even high-pressure steam, in which case the cylinders are often jacketed by steam at a pressure of 200 pounds or so. In this latter case this means a temperature of approximately 375°.

Quoting Unwin, again: "With ordinary superheated steam, superheated about 100° or 150° F., the only care necessary is to use an oil which stands a high temperature, and various universal oils, some of them distilled or charcoal filtered, are available. The flash points of such oils are from 500° to 700° F." It would seem from this that long years ago the question of high temperatures in cylinder walls had received a great deal of attention, and that it had not scared engineers to any great extent. At any rate, we still hear of superheat and high-pressure steam and we also hear very little or nothing about loss of mechanical efficiency due to using high-pressure or superheated steam.

In his article Mr. Hall makes the statement that a tight, or even close-fitting, piston cannot be used in an air-cooled engine. If he means by this that when the cylinder and piston are cold the piston diameter is less than the bore of the cylinder by several thousandths more than would be the case with a water-cooled engine, he is probably correct. Mr. Hall goes on to say that "from this it is at once apparent that the mechanical efficiency is very low indeed." This is the first time we have ever seen a tight piston advocated over a loose one for the purpose of increasing mechanical efficiency. But he should remember, of course, that nobody knows exactly what clearance there is between piston and cylinder when the motor is warmed up to its working point. He should remember also that this clearance is the important one. Now what indicates that the lower limit of clearance has been reached is that the piston will seize or stick to the cylinder walls when the motor reaches its working temperature, even when the motor is flooded with oil. On the other hand, generally speaking, the fact that the upper limit has been reached will manifest itself in a slap or knock. It will be admitted by most engineers that the proper clearance is the least which will allow the piston to work freely in the cylinder under the hottest working condition. The reason for keeping this clearance as small as possible is to prevent, for some time at least, the ill effects due to the inevitable wear which will eventually occur.
